Set 1

How to raise Anemones from seed. 193.

Effect of light influences on Garden Culture 356 - 386. 404. 452-476

Adams

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

"You see, sweet maid, we marry
A gentle scion to the wildest stock
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend nature: change it rather:
The art itself is nature."—*Shakespeare.*

JEAN JULES LINDEN,

Of Brussels, Horticulturist and Traveller,

THIS FIFTEENTH VOLUME OF "THE GARDEN" IS DEDICATED

IN RECOGNITION OF HIS LABOURS IN THE INTRODUCTION OF EXOTIC PLANTS

TO THE GARDENS OF EUROPE.

W. R.

Crops, spring, and slugs, 392
 Croquet grounds, 348
 Croton Burtoi, 425; *Dormanianum*, 425; *Evsianum*, 425, 444; *Henry-annum*, 443; *Prince of Wales*, 109
 Princess of Wales, 405, 500; *rosopictum*, 171, 609; *Williams*, 109, 443
 Crotoms for market, 199; for table decoration, 218
 Crown Imperials, 248, 369, 390, 409
 Crystal Palace Show, 443
 Cucumber disease, 412, 446
 Cucumbers, *Wells's Perpetual Bearing*, 296
 Cucumbers, culture of, 211; soil for, 248; winter, 226
 Cupania elegantissima, 406, 425, 443; *filifolia*, 12
 Cupressus macrocarpa, 71
 Curculigo recurvata for market, 199
 Cynas intermedia, 12; *pluma*, 425; *silensis*, 425
 Cyclamen, *conu vernum*, 210; *Crimson King*, 229; *persicum pictatum*, 229; *Queen of the Belgians*, 260; *Reading Gem*, 70
 Cyclamens after flowering, 164, 176, 221; and *Carnations*, 23; at *Holloway*, 229; in market gardens, 43; plunged out-of-doors, 445; treatment of, old, 371
 Cymbidium lowianum, 229; *Parishi*, 475
 Cypress, *Pyrat's* golden, 131
 Cyphokentia nana, 152, 425
 Cyrtopodium Boxallii, 426; *Calceolus*, 492; *insigne* *Mauiel*, 128; *javanese*, 425; *pubescentes majus*, 444; *Schlimi*, 229; *spectabile*, 48, 492; *acaulis*, white-flowered, 521
 Cyrtopodiums, hardy, 588
 Cytisus racemosus in market gardens, 119

D.

Daffodil, new double-flowered, 349
 Daffodils at *Kew*, 290; culture of, 202; group of, 202
 Dahlias in market gardens, 156
 Daisy, the *Paris*, 56
 Dansons, in *Kent*, 239; varieties of, 35
 Daphne indica, 38; *indica rubra*, 25, 57; *mezerum*, 246
 Daphnes, grafting, 250; notes on, 290
 Darringtons, a new, 156
 Devalia (*Micropia*) *hirta* var. *cristata*, 503; *Mariesi*, 229; *ajensis major*, 522
 Delphinium decorum, 295; *casmerina* album, 521
 Dendrobium Ainsworthii, 210; *barbatulum*, 330; *Brynerianum*, 307; *carasinodae* album, 307; *Dalhousianum*, 436; *endocharis*, 171; *lasioslossum*, 139; *Hudsonianum* var. *Fresmanii*, 329; *nobile atropurpureum*, 346; *Varianum*, 144; fine variety of, 250; *McCarthyi*, 521
 Dendrobiums in small pans, 171
 Deodars, 71
 Dentzia glacialis, 75; in market gardens, 516
 Diary, extracts from my, 167, 186, 209, 224, 247, 251, 341, 459
 Dieffenbachia Leopoldi, 509
 Dieentra spectabilis, 190, 309
 Dichorisanthras, 183
 Dionaea muscipula, large, 415
 Diplacnes, 139
 Dios grandiflora, 466
 Doodia aspera multifida, 425
 Dracenas, floribunda, 336; *Laingi*, 425; *superba*, 406
 Dracenas at *Anerley*, 424; in market gardens, 181; table, 189

E.

Echinocactus capricornus, 509; *unguis-pinus*, 137
 Edelweiss, the, 295
 Edgings, Ivy, 260; plants for, 304
 Echeusop dentatus, 475
 Elder, red-berried, 26
 Elm, a singular, 470
 Euphorbia coccineum, hardness of, 40
 Euphephalaris Fridrica Guilielmi, 509; *Hildebrandi*, 425; *Williams*, 509
 Endive, Cheswick, trials of, 275
 Epacris, 88
 Epiphyllus, culture of, 80; on *Fern* stumps, 86
 Eremostachys laciniata, 521
 Erythraea robustus, 496
 Erica gracilis, hardness of, 180, 194; *propendens* tubiflora, 229

Ericas, new Cape, 192
 Eritrichium nanum, 410
 Erysimum punium, 389
 Erythraea Crista-galli, 157; *herbacea*, 295; *maritima*, 425
 Erythronium americanum, 365; *Dens-canis*, 239
 Eucalyptus amygdalica, 61
 Eucalyptus amazona, 425
 Eunymenes, 199; pruning, 177; variegated, 86
 Eupatorium odoratissimum, 122; *Wein-*
landii, 12
 Euphorbia corollata, 155; *Lathyris*, 63
 Euphorbias, stove, 77
 Evergreens in pots, 156
 Everlasting, *Wells's*, 154
 Exhibition, International, for 1880, 203
 Exochorda grandiflora, 169, 475

F.

Faillies, local garden, 356
 Ferneries, *Surrey* in, 466
 Fern-cases, Ivy in, 91
 Fern-house, 67
 Fern, dry, for protecting, 392
 Ferns, culture of, 145; evergreen, 111, 327; from spores, 7; in market gardens, 180; in windows, 177; Moss-clad tree, 32; propagation of, 355; selected hardy, 172; tree, 17, 279, 321; tree, reducing roots of, 172
 Ficus elastica, 199; minima, hardness of, 228; *radicans*, 130
 Figs, market garden, 351
 Fir, Spruce, timber of, 193; structure of, 195; pruning, 177
 Flax, New Zealand, hardness of the variegated, 391
 Floor wiper, india-rubber, 308
 Flower and fruit culture combined, 94
 Flower garden arrangement, 216, 408
 Flower forcing, 123; ditto in market gardens, 11
 Flower gardening, spring, 390
 Flower shows, provincial, 355
 Flowers, Alpine, 97; ditto at *Ryde*, 364; at *York*, 427; *Finderne's*, 75, 134; from Zurich, 174; hardly at *Eastcott*, 330; at *Tooting*, 229; at *Tottenham*, 388; *herbaceous*, at *Manchester*, 465; at *Wantage*, 454; in *Yorkshire*, 318; *situations*, 97, 347; white, 407
 For the garden, 462; woodland, 440; spring, 189, 347, 348
 Forestry, ornamental, 26, 195
 Forests, New Zealand, 450; royal, 237, 300
 Forget-me-not, a good bedding, 462; a striped, 460; the *Azorean*, culture of, 508
 Forget-me-nots in market gardens, 119
 Frames, shading for, 401
 Franciscaes, 183, 190
 Fraxina speciosa, 295
 Fraxinus remilensis, 9
 Freesia rectata alba, 32
 Fritillaria Hookeri, 97; *Karelini*, 124; *recurva*, 97
 Frgmore, notes from, 74
 Frost, effects of, 27, 42, 65, 87, 88, 430; in the *Riviera*, 69; in *Devon*, 440; plants injured by, 134; protection from, 19
 Fruit and flower culture combined, 94, 137, 234
 Fruit garden, site for, 19
 Fruit box, refrigerating, 33
 Fruit, culture of, for market, 199, 215, 227, 263, 301, 355; in *Hanover*, 35, 310, 314, 383
 Fruit growing in *England*, 450, 454
 Fruit houses, ventilation of, 372
 Fruit, orchard, 37; swelling of, 484
 Fruit prospects, 364, 325; in *Kent*, 374
 Fruit rooms, 268
 Fruit shelters, 374
 Fruit trees, American, 92
 Fruit tree protection, 52, 280
 Fruit trees and rabbits, 198; best kinds for home growth, 34; in kitchen gardens, 16; in orchard houses, 92; insects on, 401; naming, 335; pruning, 79; shelter for, 392; transplanting large, 33; winter dressing, 146; trees, pruning of, 392
 Fuchsia serratifolia, 112; splendens, 189, 232
 Fuchsias in market gardens, 99; in small pots, 232; in orchard houses, 92; old and young, 124
 Fuel, straw as, 116
 Fungi in leaf-mould, 239; remarks on, 70
 Funks, varietal, 278
 Furze, cutting, 112
 Furze seed, sowing, 198

G.

Galanthus nivalis Melvillei, 266
 Gardenia Fortunei, hardness of, 287
 Gardenias in small pots, 376
 Garden, a rock, in *Kent*, 491; amateur's, 450; sub-tropical, plants for, 279; wild, 286; flowers for ditto, 462; winter, at *Vienna*, 123; effects of local influences on, 404, 452, 476; shrubs for small, 295; the plough in the, 502; winter, 53
 Garden labels, 245, 483
 Gardening, in *Russia*, 173; landscape, M. André on, 447; spring flower, 300; wild, in *Hyde Park*, 289; American wild, 501; children's, 329, 370, 400, 476
 Genestylis Hookeri, 38; tulipifera, 325
 Genista prostrata, 486
 Gentiana acialis, 369; affinis, 295; *bar-*
varica, 275; *verna*, 389
 Gentians, Alpine, new varieties of, 520
 Geomom concinna, 346; gracilis bulbosa, 443
 Geranium, Anemone-leaved, 84; *armen-*
num, 496
 Gesneria Cliftoni, 57; *macrantha*, 246
 Gladioli and their culture, 240; in pots, 247; wintering out-of-doors, 493
 Gladwyn, the, 126
 Gloxera jasminiflora, 365
 Gloxinia, Duke of Connaught, 425, 444; *Xantho* Khan, 454
 Gloxinias at the year round, 415, new, 145; spotted, 162, 175; seedling, 189
 Goat moth, the, 226, 249, 302
 Goldsmithia isophylla, 56
 Gooseberry cuttings, 483
 Goose seed, sowing, 198
 Gracillaria syringifolia, 443
 Grafting *Daphnes*, 250; fruit trees, 315; remarks on, 46
 Grape Golden Champion, 274, 334
 Grapes, culture of, at *Bristol*, 350, 324; in market gardens, 213, 262, 325, 335; at *Oxford*, 224; from *Vines* raised from eyes the same year, 349, 420, 440, 450; late, 35; thinning, 420
 Grass seeds, lawn, 348
 Greenhouses, an amateur's, 138, 163, 211
 Greenhouses, heating small, 176, 211
 Grevillea robusta, 199
 Griffinia Blumenaya, 388
 Glycerium jubatum, 178
 Gypsophila cerastoides, 474

H.

Haberlea rhodopensis, 375, 450, 454, 463
 Habranthus pratensis, hardness of, 287
 pratensis fulgens, 409
 Habrochloa elegans, 23
 Hemanthus albus-maculatus, 109
 Hairberbs, annual, 356
 Hairs, plant, forms and uses of, 61
 Hannellus arborea, 101; *Zuccariniana*, 126
 Haricot, green, 247
 Heath, Cape, 96, 102; culture of, 243; soft-wooded culture of, 480; ditto, planted out, 84
 Heating and ventilating, 78; in cold weather, 30, 55
 Heating, for the, for, 60; bottom, Mr. Baines on, 95; hot water, 494; materials for, 200; oil stoves for, 217; small houses, 7, 51, 170, 211
 Hebecladia latifolium, 55
 Hedges and screens, 362
 Hedges, cutting, 27; cutting down *Ar-*
bustus, 225; Holly, 220; *Rose*, 277; town square, 280
 Hedychium, 96
 Hedyardum humile, 424; *Mackenzii*, 520
 Helianthus argyralis, 109
 Heliotropes in market gardens, 119; in winter, 94
 Heliolebes in pots, 163, 391; trial of, 33
 Heliolebes guttatus, 247; *maritima*, 137
 niger, 109; orientalis, 260; viridis, 117
 Hepaticas in masses, 280; seedling, 287
 Hesperochiron punium, 455
 Hibiscus, *Rees*, 455
 Hoes, spade, 204
 Hollies, roof-eaten, 288; variegated, 74
 Holly berries, scarcity of, or substitute for, 46
 Holly hedges, 226, 362
 Hollyhocks, seedling, 118
 Holbuds and their uses, 121
 Hotels, *Japanese*, for edging beds, 512
 Houses, glass-fronted, 77; intermediate, 29; heating small, 31; leather and span-roofed, 161
 Hoya bella, 131, 334; *carnea*, 214
 Humphreys, H. Noel, the late, 508, 521

Hyacinth, Duke of Connaught, 277
 Duchess of Connaught, 260; *Salmon King*, 266; *King of the Reds*, 266; *Leviathan*, 266; the *Sultan*, 266; with many flower-spikes, 266
 Hyacinthus, cultivation of, in *Holland*, 308; *Roman*, 111; select, 267
 Hybernia defolioria, 169
 Hyile Park, wild gardening in, 280
 Hydrangea, climbing, 257, 301; *Thomas Hogg*, 55; *paniculata grandiflora*, 289
 Hydrangeas, blue, 103; hardness of, 23, 138, 126; in market gardens, 118
 Hypogymna dispar, 382

I.

Iberia gibraltarica, 493; *Semperflorens*, indoors, 171
 Ice houses, 192; circular, 89; economical, 69
 Ice storing, 91, 161, 297, 239, 261, 286, 322
 Idesia polycarpa crispata, 471
 Ilang-Ilang, 239
 Imantophyllum concinnum, 434
 Insects, destroying, 13; on fruit trees, 401; *Rose*, 421, 461
 International Horticultural Exhibition for 1880, 498
 Iochroma longiflora, 475
 Ipsea speciosa, 229
 Iresine brillantissima, 228
 Iris alata, hardness of, 23; *fetidisissima*, 186; *Kempferi*, seedlings of, 247; longipetala, 497; *reticulata*, 206; *Telfordii*, 490; *tenax*, 454
 Irises, 296
 Ivy in Fern cases, 91

J.

Jasminum Hirsutum, 96
 Jurgemannias, culture of, 217
 Justicia speciosa, 33

K.

Kauri Pine, 169
 Kale, variegated, 344
 Kalmianthes, culture of, 87; in market gardens, 130
 Kennedy coccinea, 96
 Kentia MacArthurii, 346; *Wendlandiana*, 346
 Kew Gardens, debate on the opening of, 230
 Kew, notes from, 31, 58, 95, 108, 130, 144, 169, 199, 227, 246, 265, 266, 290, 317, 320, 334, 357
 Kitchen gardens, cropping, 128; site for, 18

L.

Label ties, metal, 345
 Labels, garden, 91, 102, 122, 145, 194, 344, 345
 Laburnum sports, 522
 Lace-winged fly, 187
 Lachenalia orchidioides, 170; pallida purpurea, 57; *peruviana*, 131; ditto, in baskets, 257; quadricolor, 109, 259
 Lelia elegans alba, 454
 Landscape gardening, M. André on, 447
 Lapparia alba, 57
 Lappagerias and slugs, 60; layering, 220
 Laurels in Kensington Gardens, 508; on chalk, 245
 Laurustinus, forced, 141, 220; glossy leaved, 196, 253
 Lavender in market gardens, 155
 Lavender, *Wells's*, 154
 Lawns, 397; formation of, 15; improvement of, 345; renovating, 136, 223; spring treatment of, 125
 Leaves, culture of, 239
 Leaves, skeletoned, 45; forms of, 515; diseased, 522
 Lettices, forcing, 192; preventing seed-pods in, 396, 311; winter, 295
 LIBRARY—
 "Chemistry of Common Life," 354

J. LINDEN.

M. JEAN JULES LINDEN was born at Luxembourg on the 3rd of January, 1817. He was educated at the Royal Athenæum of his native town. Before entering upon his travels he spent a few years in botanising in the Grand Duchy of Luxembourg and the Belgian Ardennes. Subsequently he went to Brussels to attend the classes of the Faculty of Science. Already he longed for distant explorations. The study of geography, botany, and geology engrossed most of his time. He made such progress in those sciences, that at the early age of nineteen he attracted the notice of Count de Theux, then at the head of the Belgian Government, who had recently decided upon sending a scientific mission to Brazil. M. LINDEN was appointed to bring that mission to a successful issue. The Count authorised him to appoint as companions two scientific men, and he chose M. Funck and M. Ghiesbreght (the former is at present manager of the Zoological Gardens at Cologne; the latter is well known by his botanical and zoological explorations in Mexico, where he seems to have taken up his abode). The three travellers sailed from Antwerp on the 2nd of October, 1835, and reached Rio de Janeiro after a tedious voyage, lasting well nigh three months. In those days steamers in Atlantic waters were unknown, and South America was all but a sealed book to explorers. The grand aspect of the Brazilian coasts, but especially that of Rio Bay, and the first virgin forests that met his gaze made a deep impression on our traveller. It was with real enthusiasm that he started on horseback to explore the regions of the interior—little known at that time—tracing his route through Morro Quemado and Canto Gallo, in the direction of the Rio Parahiba, which he crossed on the territory of the Puris Indians. He explored in succession the provinces of Rio, Spiritu Santo, Minas Geraes, with his travelling companions, and thereafter visited alone the southern provinces of St. Paul and St. Catherine. The mission returned to Belgium in March 1837 with considerable collections both botanical and zoological, and the three travellers had the honour of exhibiting their discoveries at the Royal Palace before King Leopold and Prince Albert. His Majesty conferred on each of the explorers a gold medal as a token of his regard and satisfaction.

Encouraged by the success obtained in this first expedition, the Belgian Government entrusted to the same travellers a second mission, more important than the first. Its object was the exploration of the higher Antilles, Mexico, and Guatemala. They left Havre in October, 1837, and reached Havannah at the beginning of December. They began their researches in the north-western region of the island of Cuba, and their collection of plants was sensibly increasing in quantity and importance when they received an order to join the Diplomatic Mission which the Belgian Government was sending to Mexico. They landed at Vera Cruz in March, 1838; the Mission arrived in Mexico after halting for a week at Jalapa, during which time the environs were carefully explored. Soon, however, our naturalists found the capital of Mexico irksome; they therefore parted with the Chief of the Legation, equipped themselves, and started afresh for the interior, regardless of the war that was then raging between France and Mexico. They visited the plateau of Anahuac, the volcanoes of Popocatepetl and of Iztaccihuatl, the Cofre de Perote, the peak of Orizaba, and the eastern slopes of the Cordilleras. Two years were devoted to this expedition, when the travellers embarked at Vera Cruz for Campeachy, whence they extended their explorations to every part of the Yucatan peninsula. In one of these excursions M. LINDEN was subjected, at La Leguna de Terminos, to a severe attack of yellow fever, from the effects of which it took three months to recover. Having reached by sea the State of Tabasco, our travellers explored it as well as that of Chiapas, and made their way to the northern regions of Guatemala, at that time in a state of revolution. They fell back on the Mexican Gulf, having visited in the course of their explorations the ruins of the ancient cities of Palenque and Ocosingo. M. Funck and Ghiesbreght on their return passed through Guadalupe de Frontera in August, 1840, whilst M. LINDEN, still a prey to fever, could only start the month following, passing through Havannah and the United States. He arrived in Belgium in February, 1841, having been absent four years and four months. The scientific results of this memorable journey were considerable. Since Humboldt no exploration had been prosecuted and brought to a successful termination with resources so moderate and surrounded with so many difficulties. War, illness, small and great privations constantly recurring, bad roads, numberless dangers, all these failed to abate the indefatigable perseverance of these pioneers of natural history in the New World. Without counting the innumerable dried plants that were distributed among the herbariums of Europe, we must mention, as relating more particularly to horticulture, the introduction of the following live plants, viz., *Aphelandra aurantiaca*, *Gesnera cinnabarina*, *G. zebрина*, *Abelia floribunda*, *Dion edule*, *Beaucarnea tuberculata*, *B. glauca*, *Ceratozamia mexicana*, *C. muricata*, *C. Miqueliana*, *Astrocarum mexicanum*, *Brahea calycarea*, *B. nitida*, *Chamerops staurocantha*, *Chamædorea Ernesti-Angusti*, and other species, *Cibotium princeps*, *Oreopanax dactylofolium*, and many valuable Orchids.

With M. LINDEN the passion for distant expeditions increased with years. He had scarcely set foot on Belgian soil before he was planning new discoveries; a craving for the unknown, the legitimate attraction that attaches to fame, induced him again to visit the New World. This time Columbia was the object of his attention. Having been put in communication with Humboldt, he received from him valuable information concerning the regions which he was about to explore. Again delegated by the Belgian Government, he set sail from Bordeaux in 1841. The vessel put into Cadiz harbour, and on the 24th of November resumed its voyage and anchored on the 27th of December on the shores of Venezuela. M. Schlim, a brother of M. LINDEN on the mother's side, accompanied him. After having cursorily examined the

vegetation of the torrid zone of Venezuela from La Guayra to Maiquetia, he directed his steps towards Caracas, whence he began a thorough exploration of the maritime Cordilleras, travelling over every part of the province of Caracas, beginning with the ascension of the Silla and Naiguata. On the 5th of May following he organised an excursion to the interior. He directed his steps towards the west, across the lovely valley of Aragua, passing through San Mateo (where was born Bolivar, the *libertador*), Maracay, the lake of Tacarigua, and stopped awhile at Valencia. Then he crossed the mountains on the coast in order to reach Puerto Cabello, whence he made his way in the interior of the continent by the province of Barquisimeto. The forest of San Felipe and the mountains of Aroa were visited, and on the 1st of June he entered Barquisimeto. He explored the extensive steppes of Quibo, covered with Opuntias, Cappariss, and Mimosas, as well as the Trujillo chain and Tocuyo. But here a terrible accident threatened to bring the expedition to a fatal end—a sudden rise of the Rio Tocuyo having stopped its progress. It was, however, decided to force the passage despite the rapidity of the current, and M. LINDEN had the mortification of seeing carried away by the river several of his mules, losing at the same time his reserve clothing, valuable instruments, several reams of drying paper, &c. The party arrived in bad condition at Humucaro Viejo, where the expedition stayed a few days before attempting the ascension of the Cordilleras. A week afterwards M. LINDEN crossed the Paramo de Mucuchies (4012 metres), and two days afterwards arrived at Merida, where he fixed himself for a time, visiting the surrounding country and making new discoveries. Without leaving the high mountains of the Eastern Cordilleras, the journey was prosecuted through San José de Cucuta, Pamplona, Socorro, Velez, Tunja, as far as Bogota, the capital of New Grenada. This was in October, 1842, six months after leaving Caracas and following dreadfully bad roads, but in the midst of natural scenes of infinite beauty and variety, consisting of the productions of the hottest climes as well as those that grow on the tops of high mountains. Two months were spent at Bogota, and these M. LINDEN took advantage of to explore the environs of that town, where he succeeded in collecting some interesting plants. In December, 1842, M. LINDEN came down from the cold regions to the valley of Magdalena, and, passing through Fusagasuga, Pandi, over the celebrated bridge of Icononzo, through Melgar, he crossed the river in order to reach Ibagué, across naked plains which extend as far as the first hills of the central Cordilleras. From Ibagué our traveller carried on his investigations in all directions, crossed the chain of the Quindío as far as its western slope, and spent several weeks in the neighbourhood of the now extinguished volcano of Tolima, the summit of which (5616 metres), conical in shape and of dazzling whiteness, is seen from all the surrounding country. Having returned to Ibagué, M. LINDEN resolved upon going towards the north, through Ambalema, Honda, Guaduas, Bogota, Tunja, Pamplona, Merida, Trujillo, Varinas, a part of the Llanos of Orenoco and Carabobo, whence they laid their course towards Caracas, which was reached on the 17th of August, 1843. More than fifteen months were spent in this expedition, which was unusually fruitful as regards the discovery of new plants.

His journey homewards, after visiting Sierra Nevada and Cuba, took place through the United States in 1844, and he re-entered his native town in 1845, after having spent ten years in dangers and privations, which had shaken a constitution naturally robust. His last journey was without doubt the most fruitful of the three in a scientific point of view, especially as regards horticulture. So many fine Orchids were discovered, that Lindley collected them together and described them in a special publication ("Orchidaceæ Lindenianæ"). Masdevallias, Odontoglossums, the Oncidiums of the higher Cordilleras, Selenipediums, Uripedium Lindeni, and all the Angulea known at the present day, &c., made their first appearance in Europe. Messrs. Veitch had not at that time established themselves in London. Loddiges & Rollisson were then the chief dealers in Orchids. To M. LINDEN, too, we are indebted for the Bejarias, Thibaudias, the Cyanophyllum magnificum, twenty-five species of Oreopanax and Aralias, Eucharis, Maranta alba and roseo-lineata, and hundreds of others. The numerous and brilliant discoveries made by M. LINDEN suggested to him the idea of forming an establishment specially devoted to the introduction of new plants. This he commenced to do at the end of the year 1845, in his native town, and his houses were soon filled with new Orchids and other plants which he had acquired in Venezuela or New Grenada. MM. Funck and Schlim were also dispatched by him as collectors to regions in which he had noticed plants which he had been unable to bring home with him. This establishment, though comparatively small at first, made rapid progress. Transferred to Brussels, it soon supplied Europe with plants, and took the first place among establishments devoted to the introduction of novelties. About this time M. LINDEN sent collectors for many successive years to Columbia, Mexico, Guatemala, and Brazil; also to Peru, Assam, Java, New Zealand, and, lastly, to New Caledonia and the Hebrides.

On his return to Europe M. LINDEN was appointed Director of the Zoological Gardens at Brussels, a post which he filled for ten years. From 1853 to 1867 he represented in this town the United States of Columbia in the capacity of Consul; and since 1867 he has been Consul-General for his native land, the Grand Duchy of Luxembourg. In 1851 the first honorary reward was granted him by King Leopold I., who created him a Knight of his Order; in 1864 he was promoted to the grade of officer, and in 1871 to Commander of the Order. Various Sovereigns of Europe also conferred distinctions on him on account of the services which he had rendered to botany and horticulture. At all the great international exhibitions M. LINDEN took the highest awards. At Brussels in 1864; Amsterdam in 1865; London in 1866; Paris in 1867; St Petersburg and Hamburg in 1869; Ghent and Vienna in 1873; Florence the year after; Cologne in 1875; Brussels in 1876. No one could oppose him successfully as regards new plants, and the reputation of his establishments at Brussels and Ghent has spread throughout the world. The number of live plants introduced by him or his collectors amount to over 2000 species. We will only quote a few: Orchids, 510 species, including 59 kinds of Odontoglossum and 37 of Masdevallia; Palms, 137; Aroids, 86; Gesnerads, 77; Bromeliads, 85; Melastomads, 57; Acanthads, 23; Rubiaceoous, 51; Ericaceoous and Vacciniaceoous plants, 116; Marantads, 49; Tree and other Ferns, 113; &c.

Such is some of the work of the man whose biography we have just sketched. His influence on the progress of horticulture has been considerable. Not only has he contributed personally to the advancement of science, but we must also place to his credit what he has done by means of collectors. He has created a generous emulation among plant importers, especially in England, a commercial undertaking which has been of great benefit to horticulture in general.

M. LINDEN, whose portrait we publish, is a man of tall stature and strong physique, which years do not seem to impair, notwithstanding the adventurous life which he has led. He is sixty-two years of age, kindly in disposition and

cheerful in conversation, which all who have the good fortune of knowing him appreciate. His knowledge is very extensive. He speaks the dialect of Luxembourg, French, German, English, and Spanish with equal fluency. The thousands of specimens of dried plants which he has distributed among the herbariums of Europe have made his name famous in connection with botany. Moreover, he has established along with M. T. E. Planchon a publication, with the view of recording his discoveries, the "*Plante Columbianæ*," and, with the help of M. H. G. Reichenbach, he has published a magnificent folio, filled with coloured plates of the finest Orchids of his hothouses, the "*Pescatorea*," thus named in honour of M. Pescatore, a great lover of Orchids, at St. Cloud. Under the name of "*Hortus Lindenianus*," two parts have been issued of a work devoted especially to the plants introduced by him. The journal "*L'illustration Horticole*," edited for sixteen years by M. Lemaire, having become in 1869 M. LINDEN's property, he entrusted its editorship to M. Ed. André, who for the last ten years has described in its pages not only M. LINDEN's new plants, but also those of other countries. Our only wish is that such a man may live long to continue the good work to which he has devoted his life, and encourage young travellers to follow his footsteps.

*Globe-flowers in the Wild Garden.*

THE GARDEN.

VOL. XV.

GARDEN PLANTS FROM JAPAN.

It is not too much to say that notwithstanding the enormous number of beautiful trees and plants already introduced into Europe from this far-off land, whose vegetation may be said to be so near and dear to our gardens, there yet remains a large residue, not of things less beautiful, but, on the contrary, of trees and shrubs most remarkable and characteristic quite unknown to this country. How this has come about is a question to be answered fully and satisfactorily by those who have so energetically explored its riches in the most cultivated parts; but perhaps a mere passer-by who only spent a month in this unique island may be able to give some data on such a point, and also indicate, however lightly, what riches must be in store for us from the large areas of unexplored lands, of hill and dale, of wood, or wild seashore. This glowing prospect of a coming wealth of beauty must needs have a shadow, for it is evident there must be some good reason why such desirable forms have never been sent us by any (as far as I know) of the indefatigable botanists who year by year have poured into our lap, as it were, so many riches; and briefly it is this, that, owing to the moisture and heat of a Japanese summer, these trees grow so luxuriantly that they never perfect seed, and sometimes are never known even to flower, as I am assured, but this must be clearly an exaggeration. It is a fact, however, that many trees which seed abundantly in China, and thus have been long ago introduced into Europe, where they also perfect seed or fruit, in Japan rarely or never are known to do so, and two well-known instances will illustrate this plainly, thus giving a clue which the Japanese climate explains still more fully. The beautiful *Salisburia adiantifolia*, or Maiden-hair tree, which adorns many an English garden, seeds so abundantly in China and in the south of France, that its Almond-like nuts are used as an article of food, while in Japan so rarely does it fruit, that when at Kama-Kura, admiring the celebrated *Salisburia* tree there, said to be the oldest in the country, planted long ago by some warrior, who placed it in the court of the temple, an old resident told me that he had never been able to discover any seed on it, though he had examined both it and many other trees at all seasons of the year for the last ten years. A still more striking instance is afforded by the *Paulownia imperialis*, a tree whose glorious flower-spikes are succeeded by such a mass of seeds in the south of France that it becomes unsightly, and even dies from exhaustion, while in its native country, Japan, it is rare to find a single capsule on the tree, as far as my experience goes, though the flowering is profuse. Want of seed and difficulty of propagation by other means, as well as the sad losses caused by the long voyage to Europe, must surely be the reason why a hardy evergreen tree such as *Machilus Thunbergi* is not well

known in our gardens ere this; a tree which is remarkably beautiful on the sacred island of Enoshima, large in stature, spreading as an English Oak, with leaves disposed on the ends of the branches something after the fashion of a *Rhododendron*, but of a clear, fresh green colour and somewhat undulated at the edges, and whose great trunk, now silvery, now mottled with red stains, enhances the charm of its foliage and habit. *Litsea glauca* and various *Ilexes* of the richest foliage and colouring must not be omitted from the list of strikingly beautiful trees, which should be ours at some future date; and a walk by the seaside, where the *Eunymus* bushes grow green amid the drifting sand, shows still further treasures, among which two *Photinias* are most prominent. *Photinia glauca*, with large, pale green, leathery leaves, and whose white panicles of flower are like *Spiræa Lindleyana* in shape, braves the sea with impunity, while its lesser congener, *Photinia arbutifolia*, nestles in the undergrowth near, and in spring produces flowers delicately coloured as Apple blossom, which contrast with the scarlet-stained leaves on old shoots, and atone for a somewhat straggling growth. It certainly seems strange that *Photinia serrulata*, which is common in many gardens, should be the only kind well known to us, when these two vie with the familiar *Eunymus* in Japan in braving the severest blasts of the sea, and yet, if ever introduced, are practically unknown to us. *Pittosporum Tobira*, which is less hardy, grows abundantly where there is a little shelter, and *Pinus Massoniana* is the first tree that boldly casts its long arms seaward, as if to defy the fury of a Japanese tornado. *Wistaria* drapes the land side of each bush, and the wild pink and orange *Lilium bulbiferum* grow abundantly down to very high-water mark, where the Venus-ear shells (*Haliotis*) strew the beach with their bright hues, a contest of colours between *Flora* and *Venus*. Inland there are again many fresh subjects of interest, but before closing these remarks I would say a few words on a climate so unlike our own, which yet gives us so many hardy plants. It is truly a case where "extremes meet," for Japanese winters are bright, dry, and cold, while ours are cloudy and wet. With them the flowering of the *Azalea* and the commencement of the summer heats is the signal for deluging rains and thunderstorms, which continue all through the long, hot summer, which a country mainly situated between the parallels of lat. 32° and lat. 42° must necessarily endure or enjoy, as the case may be. Hence vegetation is so stimulated that rank growth is made rather than solid, fruit-producing wood, and flowers, however freely produced in spring, are abortive, and to this we owe much of our success, as well as failure, our drier summer making up for less heat, and so causing a more solid growth. Of autumn they have but little, the change to cold coming very suddenly,

while we constantly prolong that season up to December. The causes are these: Japan has a vast continent to the west, a warm gulf stream to the south-east, and a cold current to north, so the east wind is mild and wet, and westerly winds dry and bitterly cold in winter, while with us, as is well known, conditions are almost exactly reversed, causing corresponding differences of climate. This being once fairly understood, it is evident that our cold, dry, easterly winds are those that most try Japanese vegetation, and that any plant that comes from the west coast of Japan, even though it be far south, is so exposed to dry, cold winds in winter, that it will withstand anything that our ordinary winters bring us, but those from the eastern side of the island, south of the district near Yokohama, cannot be trusted, while in the southern island vegetation becomes tropical.

Scarborough.

DOUBLE PIRETHRUMS.

I THINK I never before saw the double *Pyrethrum* in such fine character as at Mr. Robert Parker's nursery, Tooting, in the month of June last. Probably the cool, moist season had something to do with it, and a good deal was due to the fine soil in which they were growing—a rich, light, sandy loam, that appeared to suit *Pyrethrums* exactly, and in which they are carefully tended. The flowers were very large and full, and the colours brilliant, especially in the case of some of the newer varieties. I have also seen these *Pyrethrums* very fine in private gardens during the past summer, and I am glad to perceive that cultivators are becoming alive to their great value, both as decorative plants for the open border and as excellent and most useful subjects to cut from during the time they are in bloom—from early in May till late in October in the open air. One great advantage about the *Pyrethrum* is, that it is thoroughly hardy; but in all ill-drained soils wet will do the plants harm; especially slugs will be active in eating out their hearts. In autumn and spring slugs are very apt to prey on the *Pyrethrum*, and more especially in spring, when the young growths are forming. Choice varieties should, therefore, be fenced round with a slug guard of some kind until, by means of division, the grower has more than one plant of each. One of the best guards of this character is a piece of perforated zinc, 4 in. or so in depth, placed in the form of a collar round a plant necessary to be protected.

As there are now a large number of varieties, it is perhaps well to give a selection of some of the very best, taken from Mr. Parker's collection, which comprised all the newest kinds. We will begin with Brilliant, rich rosy-purple, flowers very double, and fine quality; Chamois, buff, with bronze centre; Coquette, delicate pink, very pretty, large and full; delicatissimum, bright rosy-lilac, very fine; delicatum, pure white, very good indeed; Dr. Livingstone, very pale lilac, distinct and fine; Diadem, bluish, large and full; Emile Lemoine, purplish-crimson, tipped with golden-yellow, striking in appearance, very large and double, one of those fine and distinct varieties that attract attention at once; Floribundum plenum, rosy-pink, a variety with a good free-branching habit; Fulgens plenissimum, rich carmine, extra fine quality, and good dwarf habit; Gustave Heitz, rich rosy-red, with orange centre, one that should be in a limited collection; Hermann Stenger, rosy-lilac, a variety of the finest quality and good habit; Imbricatum plenum, rich purplish-carmine, very fine, the centre of the flowers being prettily tipped with white; Gloire d'Italie, bright deep magenta, very fine indeed, one of the best; Icaride, bright purplish-carmine, extra fine; Le Dants, bright shining rose, with orange centre, flowers very large and double; Madame Monier, rosy-blush; Mlle. Patti, carmine-rose, a good dwarf-growing variety; Michael Buckner, rich rosy-crimson, with orange centre, remarkable for the large and double character of the flowers; Mrs. Dix, bluish, shaded with purple, remarkable for the size and great beauty of the flowers; No Plus Ultra, delicate bluish-white; Nemesia, lilac-carmine, fine and double; Peau Rouge, rosy-crimson, very fine and distinct; Progress, rich crimson, one of the finest; Rubrum plenum, rosy-purple circumference and deep rose centre, very fine indeed; Triomphe Denay, pale lilac, large and fine; Virginal, pure white, the centre tinted with orange; and Voie Lactée, pure white, suffused with delicate pink. Any dozen selected from the foregoing would form a good collection to commence with. The newer introductions show not only a tendency towards a larger size and more symmetrical shape, but also towards a greater depth and variety of colour. Such a fine variety as Progress well deserved its name, for it is a decided advance towards the fine crimson hue we are desirous of seeing present in the flowers. The best time to make a bed or plantation is in early spring.

There is this advantage about it, that the plants have not to stand the rigours of a winter without being well rooted into the soil. If the grower should be led to think he could get better plants in autumn than in spring, he can pot them up and winter them in a cold frame, and so get them well established before turning them out in the open ground. A good, free loam, well manured at the time it is deeply dug, suits the *Pyrethrums* well, and in it they stand a good deal of drought. I have seen beds of *Pyrethrums* doing finely that were well mulched with manure and leaves in early summer. This fed the roots near the surface, and its presence told in the increased size and brilliancy of the flowers. This dressing or mulching can be forked in during autumn, and a fresh supply given early in spring. Any variety can be readily propagated by dividing the roots. They throw out side shoots or growths during the summer, and if these be removed in the autumn, and potted singly into small pots, and wintered in a frame, they grow to a good size in spring. Another good plan is to prick out the offsets into a prepared bed of light, free, sandy soil, and cover it with a small frame or hand-glass. Slugs must be looked after, and killed. The single *Pyrethrums* are, to a great extent, lost to cultivation. There has been a kind of craze for double flowers, and in the struggle for existence which fashion decreed, the single forms went to the wall. They may become popular again, as the single Dahlias are just now. The great danger of these changes in floral fashion consists in this, that they lead to the neglect of certain plants, which, while under a shadow, become lost to cultivation. We want more harbours of refuge in the way of old-fashioned and botanical gardens to take care of such plants that the whim of the moment overlooks.

D.

Japanese Primroses Out-of-doors.—In answer to "Primula" (Vol. XIV, p. 563) allow me to say that our soil here is not too light for these Primroses, and that *P. cortusoides amena* does but little better here out-of-doors than japonica. The improved varieties of it, however, are magnificent in pots, and the simple protection of a cold or frost-proof pit is found sufficient for them both.—D. T. FISSE.

—It is to be regretted that the plate representing the varieties of *Primula cortusoides amena*, or *P. Sieboldii*, as it ought to be called, was labelled "Japanese Primroses." It has only, as I felt sure it would, caused confusion. The Japanese Primrose *par excellence* is undoubtedly *P. japonica*, and no other species ought to usurp its title. *P. Sieboldii* (*cortusoides amena*) ought to be called Siebold's Primrose. It is perfectly hardy, but, like most of the Primulas, capricious. I can do no good with it at all except in pots, but a few miles off at Ashridge my neighbour, Earl Brownlow's gardener, Mr. Gray, grows it without any trouble in the open border. I saw *P. japonica* growing like a weed a year or two since in Mr. Latimer Clark's wild garden at Hitherwood, near Sydenham, and a Cheshire correspondent once told me that he knew a garden in that county where the pretty little *P. nivalis* flourished and seeded itself in all directions like a Cowslip. The only one of the genus which has this delightful habit here is the Bardfield Oxlip, the true *P. elatior* of Jacquin, which the late Mr. Doubleday, of Epping, sent me a few years before his death.—H. HARPER CREWE, Drayton-Beauchamp Rectory, Tring.

How to Treat Plants Inclined to Ramble.—Those of your readers who wish to grow the *Calystegia* and *Egopodium Podagraria* fol. var. (recently noticed in THE GARDEN) or any other plants with a like propensity to ramble may easily do so by simply planting them first in an old tub or pot, and then plunging it nearly to its rim in the desired spot. *Tropaeolum speciosum* may be successfully grown in this way, with the advantage of knowing where to find it when it is wanted. Treated in this manner nearly all of these beautiful subjects may be associated with the most choice Alpines without becoming mere weeds; and, as for effect, let a *Calystegia* or *Tropaeolum* allowed to ramble at will over a dead branch speak for themselves.—F. GIFFORD, Edinburgh.

Buphthalmum Cordifolium.—This is a remarkably fine plant for the wild garden; it has large and handsome foliage, and large Sunflower-like blooms of a good orange colour. It is extremely hardy on any soil, and its true place is the wild garden among the larger perennials, or, still better, in a small spreading colony by itself. The species belongs to a very small family, some of which are tropical and others European, but none, so far as I have seen, is so suited for the wild garden as *B. cordifolium*, which attains a height of from 3½ ft. to 5 ft., and comes from Hungary. Like almost everything else of a similar character, there is no trouble whatever in either cultivating or increasing it.—V.

THE FRUIT GARDEN.

FAILURES AMONGST INDOOR PEACH CROPS.

In discussing this subject, I can only refer to the general causes of failure, for a cultivator may fail in many cases through causes entirely local. One of the commonest causes of failure is ill-ripened wood, a condition which should hardly exist under glass anywhere, in England at least, for, with the aid of a glass roof and the option of closing and opening the house at pleasure, there should be little difficulty in getting the wood of Peaches properly matured. It is simply a question of keeping up the necessary degree of temperature during the summer by judicious ventilation, and especially of economising sun-heat in autumn. Attention to these matters should not be relaxed until it is seen that the young shoots are hard, brown, and ripe, and the leaf and fruit buds prominent and well developed. Maturity is not a question of the leaves falling, for when the cold comes they fade and fall from ill-ripened shoots as well as from those that are well matured. Indeed, the leaves will hang quite green and fresh long after the wood has become hard and ripe, if a comfortable temperature be maintained; but in such cases they fall off readily if the trees are shaken. Another question, however, is, what are the best means to secure a crop of fruit when it is known that the wood is not so well matured as it should be? In such a case the first thing to do is to cut back the most unripe extremities of the shoots to where the buds are tolerably plump and the wood hard; and the next thing is to give the trees a complete rest during the winter months, neither exciting by fire-heat nor permitting injury by frost, though a few degrees will do no harm, and they had much better be exposed to frost than subjected to a temperature above 45°, which is sufficient to excite immature buds at any season, and probably, as a consequence, cause them to drop when the house comes to be started at the proper season. This dropping of the buds is sometimes a serious evil, and it often occurs in the best-managed Peach houses, early ones particularly; but in bad cases nearly all the buds drop off the tree, except the leaf buds at the points and base of the shoots, which never drop—a wise provision of nature, for did they fall it would be the almost complete ruin of the tree, as growth would entirely depend upon adventitious buds pushing from the old wood. For years here we were afraid to cut back the shoots of a tree of the Noblesse Peach, which was in the habit of dropping some of its buds every season; for it must be remembered that it is the natural terminal leaf bud that does not drop. The end bud of a cut-back shoot is quite as liable to fall as the others, and the wood, of course, dies back during the season to the next growth, unless it be cut away at the beginning, which is the best thing to do. When trees that are not thoroughly ripened are started, say in March, they should be pushed on gently in a day temperature ranging from 50° to 65°, accordingly as the weather is dull or sunny, and at night the temperature should be allowed to fall to 40° or 45°. The borders should be kept in a properly moist condition, but little moisture should be given overhead. A slight dewing will be sufficient on the afternoon of sunny days. In ill-ripened trees the leaf buds are apt to push in advance of the fruit buds, and when they get too much in advance the flowers do not open, and failure is the result. In healthy, well-matured trees the flower buds open first, and the shoots only begin to push noticeably after the fruit is set. In the case of ill-ripened trees, therefore, this condition of growth must be secured by artificial treatment, which consists in simply pinching the points of the leaf buds persistently as fast as they push, until the fruit has set, when they may be left alone. This will cause the flowers, that would otherwise have remained unopened, and which would eventually have dropped off, to expand; and when they are fully blown, and the pollen is dry and powdery, artificial fertilisation, either with the syringe on a fine day, or a camel-hair pencil, will insure a "set," when the chief difficulty may be considered over, though on ill-ripened trees a greater proportion of fruit will drop at the stoning period than otherwise ought to happen.

Another frequent cause of failure is an unsuitable temperature; sometimes the temperature is too low and sometimes too

high when the trees are in flower, and the fruit fails to set. This happens oftener in early than in late houses, as in the first the maintenance of an even temperature depends entirely upon artificial means. If the temperature be maintained at a very high figure, the fruit will not set well, but most danger is to be apprehended from a too low temperature. This is very often observed in cases in which the fruit sets just above or near to the hot-water pipes, and nowhere else. Failure from this cause is not so likely to happen when the days are bright and sunny, when with ordinary care the proper temperatures can be kept up, as in dull weather. In such times everything depends upon the judicious application of fire heat. In bright weather the heat may be allowed to run up to 70° or 75° as early in the morning as possible, and kept at those figures till the sun is off the roof, after which the thermometer should decline gradually to 45° during the night, but during dull days a steady temperature of from 55° to 60° should be maintained, with a somewhat dry atmosphere and a little ventilation back and front, and these degrees of heat should be preserved from daylight to dark during the short days. The trees may also be shaken now and then to set the pollen free, and it will do no harm whatever, but rather good, to syringe the trees to help to distribute the pollen two or three times a week, about one o'clock in the afternoon. It has been said that if the sky is constantly overcast when Peaches are in flower, scarcely any fruit will set; but that is not the case, as I have frequently, by the above means and other attentions, had a very good set on all our early trees when there has been a dull snowy sky during the whole of the flowering period. This happened only last January, when our early Peaches were in flower; yet there was quite a thick set, especially in the case of the Elrune Nectarine. As regards ventilation, it is our practice always to keep a little air in the house, both back and front, night and day, no matter what the weather may be. A very small chink of air keeps the atmosphere fresh and sweet, and that much should be given, even if coals are burned to keep up the extra heat required in consequence of the escape of warm air at the ventilators. In old houses, glazed with short panes and many laps, and not unfrequently breakages here and there, it was unnecessary to open the ventilators; but now, as houses are glazed with long panes closely overlapping each other, little air gets in, except by the ventilators.

In lately constructed Peach cases or glass-covered walls failures are far more common than they need be. In some places, in fact, such structures are, through mismanagement, little better than open walls. They are generally used for other purposes besides Peach growing; they are often, indeed, filled with plants, and to keep these comfortable the house is frequently kept too warm for the Peaches between November and April, and the consequence is, that the trees begin to move and come into flower too early in the season, and either fail to set their fruit, or the latter drops off before stoning, simply through a prolonged low temperature. Peaches that flower in February, or even early in March, in an unheated glass case, are more likely to fail than otherwise. They should be kept back by keeping the case cool as long as possible, and if they can be had in flower in April, the chances of a good crop of evenly-swelled fruit are greatly enhanced.

Among other causes of failure, I suppose over-cropping need scarcely be alluded to, its effects being but too well known. There is little prospect of fruit the season following an excessively heavy crop; but all trees are not alike, and hardly any rule can be laid down for guidance on the subject. I always crop according to the vigour of the tree, and even of the individual branches. On weak shoots the fruit at the final thinning is left about 1 ft. asunder or more; over strong and vigorous limbs much less. The Victoria Nectarine, which is an extraordinarily vigorous variety, we crop twice as heavily as any other sort, leaving the fruits from 5 in. to 6 in. apart, and frequently less, all over the tree; and, thus cropping, it stands for many years in succession, producing at the same time exceedingly fine large fruit. Grosse Mignonne is also a vigorous-growing Peach, and may be cropped heavier than some other kinds, but it is a shy setter. Heavy cropping is one way of checking excessive exuberance, and should be resorted to when trees are making strong shoots.

Very frequently failure of Peach crops is laid to the border, which is generally supposed to be too wet or too dry. My own impression is that the condition of the border has seldom anything to do with the matter. It is seldom that an ordinary, well-cared-for border is either so wet or so dry as to cause the crop to fail, either when setting or stoning, and, after these two critical periods are passed, only the grossest carelessness can cause what may be called really a failure. Gross growth from a too rich soil, or debility from the opposite cause, is of course a different thing, and in each case the remedy suggests itself. When Peach houses, either late or early, are started the border should be examined, and, if dry, watered most copiously and mulched. This will usually carry the trees on for a month or two; but, as summer advances, frequent waterings become necessary. S. W.

PEARS SUITABLE FOR NORTHERN ENGLAND.

I FIND it very difficult to lay down any straight line of proceeding for the culture of winter Pears—the whole thing is wrapped up in so many circumstances, the greatest of all being atmospheric changes. We never get too much heat, but often too much cold and too much wet, in the absence of heat; moisture and sun-heat are two essential elements in the culture of good Pears. The soil, which is various in different localities, has a wonderful effect on the growth of Pears. No doubt a good strong rich loam is the best suited for Pear culture. The border should be as rich as a Vine border, both for making good strong spurs and for growing the fruit to a good size and full of quality. The spurs should be as near the wall as possible, to allow the fruit to get the benefit of the heat contained in the wall. Root-pruning the Pear I have a great objection to, because the fruit must be small if the feeders are cut away. If my trees are too vigorous to make fruit-spurs, I ring the branches by taking out about one-eighth of an inch of bark all round with a sharp knife. This will have the desired effect of producing spurs, and the following season fruit is almost certain, the weather being favourable. The ring in the bark should be made as early as possible, when the bark will separate from the wood, and by autumn the two bark will be united, and ready to assist the swelling of the fruit in the following summer. If once a good quantity of spurs and fruit be produced, ringing is hardly ever necessary afterwards, as Nature will do its own work, and the tree bears fruit in consequence.

The varieties I now grow are very limited, and it must be taken into consideration that I am situated forty miles north of York, and I find so many of the varieties highly recommended by writers in the south to be quite useless here—some are too small, and others not at all suited for the climate. It would be difficult for me to name a promising variety that I have not tried here; quantities of them have now disappeared and are almost forgotten, and have given place to new favourites. Marie Louise is the greatest favourite of all, and no wonder, for I can supply the table with this Pear throughout the months of October, November, December, and a little into the new year; the size, if not very large, runs up to 10 oz., and it is exceedingly handsome. Our daily average use in November is about thirty Pears. I have the Marie Louise grafted and ingrafted four times over in some places, and I must say the stock has a wonderful influence on the fruit. One grafted on the white Doyenné Pear comes in very early, and often ripens on the tree by the last week in September; the next for earliness is twice grafted on the Autumn Bergamot, the one after this is three times worked, the last on the Swan's Egg Pear. I have a fine lot from this stock generally, and they are the best we have in quality. Those ingrafted on Gansel's Bergamot are great bearers and grow to a good size; those ingrafted on the Beurré Rance are in use now, and will continue through the month. Winter Nelis is the next favourite sort to follow Marie Louise. It is four times grafted, the last time on Uvedale's St. Germain's. This sort has wonderful vigour so grafted, always bears plenty of fruit, is always good, and never cracks. This sort is no use here on the Quince stock; it grows too weak. Glou Morceau twice grafted, the last time on Beurré Rance and on the south wall, is generally good and comes in for January and early in February; they are not so fine as I have had them other years; the earliest blossoms were killed in the spring, consequently they did not grow so large as usual. They are fine for stewing, and for that purpose they are being used this year. Easter Beurré is the next favourite, and a grand old Pear it is, always good; if not left to spoil itself on the trees, with a little management this Pear might be had in use for a long time. This sort I have grafted on various stocks, but none on the Quince. The sorts I have named will carry me through a winter, but I have many other good useful sorts to fill up a gap if needed. The common early summer Pears are no use here for table.

The Jargonelle is the first to be of use to me; this is grafted on the Pear stock, and is very fine generally; on the Quince it is subject to canker and useless. Marie Louise ingrafted on the Jargonelle never bears any fruit worth naming, and what it does bear is very small. I expected great things from this stock, and grafted three trees, two of which are now destroyed—the other I will give another trial, as it has a good promise of fruit-buds, after being very liberally treated at the roots, to give it strength. The blooms of this tree are very tender, and stand no frost when in flower. The next to follow the Jargonelle is that monster Pear, Souvenir du Congrès, two fruits of which will make a dish, and if eaten just when it is ripe it is delicious. It has a fine colour, and is very handsome on the table. Williams' Bon Chrétien comes in about the same time, and, like Souvenir du Congrès, requires to be gathered before it is ripe to have it fine in flavour. Beurré d'Amanlis ingrafted on Hacon's Incomparable is always very large and excellent in flavour, and will ripen on the tree or in the fruit-room. Louise Bonne of Jersey is another fine-flavoured Pear, but should always be on a vigorous stock. It is poor on the Quince stock, and apt to crack.

When I added Doyenné du Comice to my stock, I thought I had a great catch. I ingrafted it on various strong-growing stocks, and tried to palm it off as superior to Marie Louise, but Mr. Milbank pronounced it too sweet and wanting the fine aroma of the Marie Louise; however, it is a good useful sort for our climate and soil, and does well on any stock except the Jargonelle. Beurré Diel ingrafted on the Swan's Egg Pear is delicious and very large, but always a little gritty. Duchesse d'Angoulême is never first-rate here, neither is Beurré Clairgeau. Dunmore is a large, handsome Pear, and well suited to this climate; although it is not of the first quality, it is a good Pear. Hacon's Incomparable is a large handsome Pear of first-rate quality on the old Pear stock, but is rather shy in bearing; it bears well on the Quince, but the fruit is rather small. Josephine de Malines is very uncertain in quality, but bears well on any stock; not thoroughly good, except in very fine seasons, but useful for the kitchen. Beurré Hardy is a most delicious Pear ingrafted on the Pear stock. Beurré Sterckmann, Knight's Monarch, and No Plus Meuris are only very moderate sorts here. Beurré Rance never ripens here. Beurré Superfin is a good useful autumn Pear if grafted on the Quince; grafted on the Pear here it is very poor in every way. Bergamot d'Espèren in fine seasons is very useful. The gathering of Pears requires to be studied very particularly. The melting Pears will mostly bear hanging long on the trees without losing the flavour, while the gritty sorts should be gathered as soon as they show signs of ripeness, and are much improved if finished off in a warm temperature.—WILLIAM CULVERWELL, in "Gardener's Chronicle."

"Caledonia," described by Scott, Burns, and Ramsay," forms a large 4to volume, well printed and illustrated. Amongst the illustrations, which are by MacWhirter, are Linnithgow Palace, Tantallon Castle, the Hero's Targe, Fingal's Cave, Iona Cathedral, Neidpath Castle, Lochleven Castle, Fall of Foyers, and others, all well reproduced on wood by Patterson. The letterpress contains some of the best poems of the authors just named, and the book, being tastefully printed will prove a welcome gift at this season of the year. The annexed is an example of the illustrations, many of which are very good.

Nettles.—I read with the most profound amazement the statement of M. Lavalée that Nettles only grew in the vicinity of houses. We know, alas! to our sorrow, in England that beds of Nettles far removed from any house or building are as common as Blackberries. Where has M. Lavalée lived to make such an astonishing assertion? —H. HARPUR CREWE, *Drayton-Beauchamp Rectory, Tring.*

The Cretan Borage (*Borago orientalis*) is a somewhat vigorous growing perennial, bearing pale blue flowers early in spring, and in good soil having large and imposing foliage throughout the summer. Easily naturalised in any rough place, it is not worth a place in the garden proper, being very coarse in habit and occupying too much space; it should be associated with the early spring flowers. The common Borage is a very pretty plant, naturalised in dry places or banks, where it might be often welcome to those who sought it for other purposes than its beauty. *Borago laxiflora* is charming with its numerous suspended blue flowers; it grows very freely on sandy soils. The family is a small one of South European distribution.—V.

THE INDOOR GARDEN.

FINE-FOLIAGED CONSERVATORY PLANTS.

Nothing adds more to the interest attached to conservatories or greenhouses and helps their embellishment so much at this dull season as fine-foliaged plants, of which there are great numbers that are sufficiently hardy to bear the temperature of a greenhouse or conservatory remarkably well. Some of the noblest and best of these are Palms, but, unfortunately, many are deterred from growing them owing to an idea which is prevalent that they are mostly tropical plants, and require great heat, and that they soon attain such a large size as to be unmanageable in the limited amount of room that can be

afforded them. If potted in fresh soil frequently and encouraged to grow on, this would no doubt be the case, but with their roots restricted, it is surprising the great length of time they may be kept moderately small and in a thoroughly healthy condition, but to do this they must be afforded an abundant supply of water during the summer months, a season when, if the drainage is free and open, it is almost impossible to give them too much. One great advantage in growing Palms is that they will stand more hardships in the way of cold draughts, absence of bright light, the dry, heated air of rooms and corridors where gas is used, and such like adverse conditions, better than most other plants. A few years ago their high price was greatly against their extensive use, but of late they have been raised in vast quantities from seed and are

now offered at such a low rate that they are among the cheapest of plants, and, therefore, within the reach of all who wish to possess them. *Chamerops Fortunei* is so hardy that in anything like favoured localities it will stand out without protection, so that when this gets too large it may be turned to good account for planting out on lawns or other conspicuous places where it can have a little shelter from winds, which, if violent, somewhat damage the foliage. *Areca sapida*, a New Zealand species, is a very ornamental Palm of moderate growth, and very distinct in habit from the preceding, but like it it is many years before it reaches a large size, and it is a plant that always looks well, owing to its fine healthy green colour. *A. Baueri* greatly resembles it in every respect, but it is stronger growing, and, therefore, not so well adapted for small houses. *Scaevola elegans* is, as its specific name implies, a very ele-

gant Palm, having gracefully arching leaves, which, standing out clear of other plants beneath, have a very pleasing effect. *Chamerops humilis* forms a beautiful object, and, from its more compact growth and the way in which it sends out suckers with foliage near the base, it makes an admirable specimen for a vase or standing singly, so that it may be seen to advantage. *Latania borbonica* looks well, too, in the same way if placed beneath the eye, so as to show off to advantage the tops of its fine glossy leaves, and their exquisite form; but this is a variety which, owing to its spreading propensity, soon occupies a good deal of room. It is, however, a noble species where space can be afforded it, as are also the following, all of which will succeed in a greenhouse or conservatory temperature, viz., *Kentia Canterburyana*, *K. australis*, *K. Fosteriana*, *K. Bel-*

moreana, *Cocco procepeana*, *C. chilensis*, and *C. coronata*, *Thrinax parviflora*, and *Corypha australis*. Any of these are well worth growing, and are fine ornaments in any house, and when they get too large can generally be exchanged for others of smaller size, or, if not, wintered in any light sheds out of reach of frost and plunged or planted out in the sub-tropical garden during the summer, where they will be a great help in giving distinctness and character. For associating with Palms *Dracaenas* come in most usefully. They are all plants of a fine type and stately habit of growth that are easily managed, and if well cared for they are always in good condition. *Dracaena australis* is one of the best, the leaves of which are narrow and gracefully recurving, and when in a small state the plant is a very useful one for table decoration.

To this may be added *Cordyline indivisa*, *Dracaena Veitchii*, *D. cannefolia*, and *D. rubra*, all of which may be confined to small pots and kept in perfect health for many years. The soil in which these and Palms do best is tough fibry loam chopped up roughly, and in this they should be potted somewhat firm if it is desired to restrict the growth, and to keep the leaves of a healthy appearance nothing answers better than soot water, which, not being a very powerful stimulant, does not add materially to the vigour of the plants. The only insects that affect Palms to any extent are scale, which, from their minute size and the tenacious way they adhere to the leaves, are very difficult to eradicate by hand-washing, as they cannot easily be got at, especially in the case of such as have furrowed leaves or stems, in which depressions the small white scale generally take up their abode. With pot plants that can

"The Hero's Targe."

be laid on their side, the readiest way of getting rid of these pests is to use some Fowler's or Abyssinian mixture in the proportion of 4 oz. to a gallon of soft water, and syringe it on, letting it remain for a few hours, when it should be washed off again before the plants are placed in an upright position. This will prevent any portion penetrating the soil and getting to the roots or collar, where it would be likely to cause injury. Paraffin is found to be a capital insecticide used at the rate of a wineglassful to a gallon of water, but in applying this remedy it must be kept quickly agitated the whole time, or the paraffin, owing to its oily nature, floats and is not equally distributed, some parts of the plants getting more than they will endure with safety. *Dracænas* are likewise subject to scale, but not to the extent that *Palms* are, and, although they have a greater immunity from these insects, red spider frequently attacks them, especially if at any time they are allowed to get dry at the roots. These pests are easily dealt with by running a soapy sponge up the leaves, which not only takes them off but greatly brightens the foliage.

Another class of greenhouse plants that should be in every garden where vases in rooms have to be supplied, are the *Aspidistras*, the leaves of which closely resemble those of some of the *Dracænas* in their size and form, but instead of being borne up the sides of single stems like them, they have long footstalks and come from the joints of slowly creeping, fleshy roots or stolons that travel just beneath the soil. They therefore admit of propagation very readily by division, which is the only way they can be increased; this operation is best carried out in the spring just as they are beginning to grow, a time when the injured part quickly heals over. I know of nothing in the plant way equal to *Aspidistra lurida* variegata, and its normal green variety, for standing impure air, a striking proof of which may be seen in the Westminster Aquarium, where, although even *Palms* look wretched and most *Ferns* are dead and dying, *Aspidistras* are holding their own bravely, and appear as if they would bear with it all. This exceeding hardihood of constitution, coupled with its remarkably bright cheerful appearance, renders it valuable as an ornament to grow in windows in towns, where its presence would add a cheerfulness that few other plants could give. The fine bold leaves have broad bands of rich creamy-white running up them, and the contrast between this and the polished-looking green is most striking. Red-foliaged *Dracænas*, such as *D. terminalis* and *Cooperi*, associate well with it if placed one on each side or *vice-versa*, and when arranged in this way the whole has a capital effect. Although so thoroughly hardy as to endure a low greenhouse temperature, or even live outdoors in a sheltered position with very slight protection in winter, *Aspidistras* enjoy moist stove heat, and if grown in it in the spring the warmth brings out the variegation to a greater extent than it generally appears in others not subjected to such treatment. Peat likewise has a favourable effect in developing more colour, as, although they grow just as freely in loam, the plants have then an inclination to revert to their normal condition. If they have ample drainage these *Aspidistras* cannot well have too much water during the summer months, and, being little subject to insects, they seldom give trouble in keeping clean. A sponging, however, now and then is a great help, and always pays for the labour.

Burya latifolia variegata is another capital plant for greenhouse decoration, and one that, from its habit, associates well with *Camellias*, the foliage being nearly of the same shape and character, but with a good deal of colour, which is always stronger and more permanent in the old leaves than on any of the young growth, and it is, therefore, at its best in the winter. Besides having such beautifully marked foliage, the stems of the shoots are red, and when seen under artificial light, show up to great advantage. This *Burya* is said to be nearly or quite hardy, but of this I am doubtful, as I lost a handlight of cuttings that had been struck outdoors, and were left till late in the winter without any protection, when they were killed by the first sharp frost that occurred. Unfortunately, it is rather a slow-growing plant, and takes some time to get up good specimens, unless they are subjected to stove heat early in spring, so as to get a double growth out of them in a year. This may be done by giving them a rest in June, and then

starting them again where they can be shut up early in the afternoon and syringed overhead. Like most variegated plants, *Eurya variegata* is benefited by a rich, open soil, and likes liquid manure if given when growing freely during the summer. I find it propagates best if the cuttings are put in early in autumn, and placed in a cold frame under a clear bell glass, or where they can be kept close till April, and then removed to where they can have a little extra warmth to induce the formation of roots. *Coprosma Baueriana* variegata is likewise remarkable for the great beauty of its foliage, the leaves being broadly banded with rich yellow, and the centre a fine glossy green, the whole surface looking as if polished, thus giving the plant a very healthy and cheerful appearance. Seen in contrast with sombre-looking *Camellias*, the contrast is very striking, and a few good specimens of it quite enliven a house. Being of a somewhat pendulous habit, it makes a capital basket plant for suspending in windows or conservatories, and with a little tying and support by means of stakes, forms neat bushes in pots. Cuttings strike readily in heat in spring, and the only insect that affects it is green fly, which, if not taken in time, cripples the young leaves to such an extent as to quite spoil their shape and beauty. S. D.

BEGONIA REX, ITS PROPAGATION AND CULTURE.

Few plants have created a greater sensation and attained such rapid popularity, as did this species of *Begonia* on its introduction into this country. Numerous varieties were raised, and almost every establishment possessed a collection of them; now they appear to be much neglected, and one seldom sees them thoroughly well grown. It is difficult to assign a reason for this neglect, inasmuch as they are really useful for indoor decoration, and may be used with considerable effect, either in apartments, or as growing freely amongst the other inmates of the stove. Their culture and propagation are very simple, and good plants may be easily grown by anyone who possesses the convenience of a genial, regular temperature in early spring. In order to obtain young plants, cut off an entire leaf, lay it with the under side resting upon silver sand, then with a sharp knife cut through the main veins of the leaf, just below the conjunction of a small vein. Peg these down so that they rest upon the sand, and place them, if possible, in bottom heat. If such accommodation cannot be afforded them, then place the pan where it receives the greatest amount of atmospheric heat. If carefully attended to in watering they will soon emit roots where severed, and little leaflets will show themselves, when they may be carefully potted into 2½-in. pots. At this stage they are liable to the attacks of the woodlouse, which will often, if not checked speedily, clear the whole lot off. When once fairly established it does not appear to molest them. If a few *Potatoes* are placed about them, cut into halves, and the inside scooped out, placing the hollow part downwards, these pests will resort to them in preference, and may be thus destroyed. As soon as the little plants are well established shift them into the next sized pots, and from thence successively into 4-in. and 6-in. pots. The compost should consist of well-sanded, turfy peat with a small proportion of loam amongst it. The pots should be well drained, so that when fairly in growth abundant supplies of water may be given. These plants require but little air; they luxuriate in a warm, moist atmosphere, free from drying air or cutting draughts. In such conditions the leaves develop finely, and the shades of colour therein are well defined. They should, however, by no means be excluded from the light when in full growth; they should be merely screened from the hot sun. When fully grown, they may, if required for general decorative purposes, be removed to a cooler house, as they will thus be better enabled to withstand the vicissitudes of climate which the placing in apartments entails upon them. The same plants may be grown on from year to year, shaking them out and repotting in the spring. If at all leggy they may be cut off near the crown, and treated as cuttings. They will soon form fresh roots, and may be grown on again. These old plants serve admirably for the formation of larger specimens. By putting a few of them together in a 10-in. pot, a handsome mass of foliage will be obtained. A few well-grown examples placed amongst *Ferns*

Orchids, or other occupants of the warm house do much towards enlivening and creating variety therein. This *Begonia* will do well in a window during the warmer months of the year, and the effect in large light rooms is excellent, if it be associated with bright flowering plants. I may add that propagation may be carried on with facility during the summer; and, if placed in a close house or pit, they will need nothing more than the natural warmth of the season to enable them to make roots. I have myself generally preferred to propagate about July; the leaves are then healthy and free, and the young stock is of a much better description than that obtained from plants that have seen some wear and tear. In this case it is only needful to let them remain until spring, and then pot them off and grow them on as above directed. J. CORNHILL.

Byfleet.

HEATING SMALL PLANT HOUSES.

DURING such wintery weather as that which has just visited us the most important question to thousands is that of how best to keep the frost out of their small plant houses. A costly heating apparatus will often prove as expensive almost as the erection of the building, and therefore it is but natural that the cheapest method of warming should be sought for by those whose means are limited. Few methods of heating have of late been so persistently pressed upon our attention as that of gas stoves and petroleum lamps, but most of these have proved but as snares for the unwary, as it is simply impossible that the amount of heat required to exclude severe frost can be got out of the flame of a gas burner or that of an oil lamp. Heat must be proportioned at all times to the amount of combustion that produces it, and because an oil flame may give a medium amount of warmth to a small lamp stove, it does not follow that it can transmit that heat to any considerable distance beyond it; indeed, as the flame alone is the generator of heat, it is self-evident that the more the stove absorbs the less there is for the warming of the atmosphere. It is therefore only by making a costly use of lamps or stoves within a house that sharp frost can be excluded. A further drawback to these lamps is found in the consumption of air on which the plants exist, and in the unpleasant perfume emitted. Either of these results are destructive to healthy plant existence, and even if capable of excluding frost, such gain would be more than counterbalanced by the mischief done to the plants in these directions. Without doubt the simplest and least costly mode of heating small plant houses is by means of a flue, an old-fashioned method, but one that will answer every purpose, if it be properly constructed, and the fire receives efficient attention. One special advantage which the flue presents to the amateur is its comparative simplicity. Except it actually wears out, it can hardly get out of order, and the fire may easily be left to the attention of an assistant. A flue can be built with the house, or it can be put in at any time afterwards. The chief essential to its success as a heating power is that it shall, from furnace to outlet, have a slight incline, and then a fair amount of draught is assured. Too strong a draught is not desirable, the object being to secure enough heat to exclude frost, let it be ever so severe; and, to do this, it is simply necessary to keep the fire looked to, perhaps a couple of hours later at night than ought to be necessary when only moderate frost prevails. Any tendency on the part of brick fires to promote dry air can easily be remedied by placing a few pans of water upon the flue. If it be found to take longer to warm a brick flue than water pipes, at least it is longer in cooling. As a hot-water boiler for the heating of small plant houses, I have found none better than a small conical one, that does not need setting in brickwork, and which can be placed in a tool house or outhouse adjoining the plant house to be heated. One of these, costing 50s. only, will heat 100 ft. of piping—more than enough to warm any medium-sized amateur's greenhouse. That it can be used without brickwork is a great advantage, as it can be transferred here and there if required, at little cost. It is the question of first cost that most affects all amateur growers, and, if this be moderate, the future expense is of small consideration. A. D.

The Candle Plant (*Cacalia articulata*).—This old-fashioned succulent used to be very popular as a window plant, a purpose for which it is well adapted, but now-a-days it is seldom seen. I entertain a liking for quaint plants of this kind; they are singular in form and easily grown. Such is the Candle plant, which I have until lately merely regarded as a curiosity, giving it little credit for decorative value. I was, therefore, somewhat surprised to find that it could be grown so as to develop considerable capabilities in that way.

The plant itself is rather singular as regards growth. It has a straight, cylindrical, fleshy stem, of almost uniform thickness, but tapering abruptly at the apex. Its leaves, which are produced upon the current season's growth are deeply lobed, and the whole plant is of a clear glaucous green, and covered with a delicate powdery bloom. At the commencement of the summer the leaves die right off, and this is the time to form a specimen, which may be effected in the following manner:—Take a 4-in. or 6-in. pot, drain it well, and fill it with a good, light, free compost; in this insert the stems, putting several of the longest in the centre, and arranging the remainder somewhat irregularly, according to their length, finishing off by placing a row of the smallest round the edge of the pot. There will be no difficulty in finding stems of the required height, as some will be composed of several joints, the growth of successive years. Place the plant in a greenhouse or frame, or in a window in the full sun, and keep the soil moist; they will soon root and begin to grow. By the beginning of winter we shall therefore have a very pretty and unique specimen, which will be a source of pleasure the whole winter through. It thrives well in a window, and requires but little attention, bearing, without apparent distress, any neglect in the way of watering to which it may be subjected. Although the flowers are by no means showy, they acquire some little value from the fact of their being produced in mid-winter, when blooms of any kind are so welcome. I would recommend any of your readers who may not know it to give it a trial; if treated as described they will hardly fail to be gratified. I am strongly inclined to believe that this plant will again become popular, as the tide of fashion appears now to have set in in favour of plants of a succulent character and easy culture.—J. CORNHILL, *Byfleet*.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

***Primula sinensis coccinea*.**—I procured a packet of the seed of this *Primula* last spring, and have now many plants of it beautifully in bloom, some of them being quite scarlet in colour, and well deserving the name *coccinea*. They were grown in a cold frame all summer, and kept near the glass, but they were raised and kept in a warm frame until they had become established in 3-in. pots.—H. HILLMAN, *Fenay Hall, Huddersfield*.

***Crassula lactea*.**—I have grown this rather largely this season, and I can endorse all that "S." says (Vol. XIV., p. 577) in its favour. Its flowers, looked at individually, remind one of those of an *Ornithogalum*. I grow it in loam, leaf-mould, and sand, to which is added just a sprinkling of lime rubbish. During the summer months the best position in which to place it is on a shelf fully exposed to the sun, watering it sparingly. Early in September it will require more water, and it should be transferred to a light, airy house early in winter, where the temperature does not exceed 45° at night.—A. HOESACK, *Ragley, Alcester*.

Raising Ferns from Spores.—All the small-growing Ferns, including *Gymnogrammas*, *Adiantums*, *Cheilanthes*, &c., are raised yearly from spores by thousands in Mr. Ley's nursery at Croydon. The fertile fronds are laid on stages, on which have been placed a few inches of fine soil. No bottom-heat is applied, except that which is furnished by pipes running round the house under the stages; neither are bell-glass or lights used, except for very rare kinds, and seldom have I seen so many seedlings as are now to be found in this nursery. When large enough to handle, the young plants are pricked off singly into thumb pots, and placed on shelves near the glass, where they grow bushy and strong, and are soon ready for shifting into large pots for table or window decoration.—S.

***Sparmannia africana* in Winter.**—Now that greenhouse flowers are somewhat scarce, it may interest some of your readers to be reminded that the *Sparmannia africana*, one of the easiest of plants to manage, and quite free from insect pests, is now in bloom.—A. K., *Eastcott Cottage, Pinner*.

***Schizostylis coccinea* Planted Out and in Pots.**—"K.L.D." (p. 577, Vol. XIV.) evidently failed in getting good results from planting out this plant by following a wrong method, and succeeded in the pot culture by doing it well. If the suckers are planted out in the autumn singly, 3 in. apart, and in rows 9 in. apart, they will form strong flowering plants by next autumn, with one-tenth of the labour bestowed on pot plants. The strongest should be lifted for house decoration not later than the end of August, and potted ten or twelve together in good soil, after shaking off all the soil and removing all the suckers for replanting for the next year's supply. The pots should then be placed in the shade for a few days and kept well watered, and by the end of October every plant will be throwing up a flower stem, and the foliage will be everything that could be wished.—T. B.

TREES, SHRUBS, & WOODLANDS.

GOLDEN-LEAVED CHESTNUT.

(CASTANEA CHRYSOPHYLLA.)

CAN any of your readers give some account of the growth of this tree either in England or Ireland? I hardly expect to hear of its existence in the north. There is a specimen here 20 ft. 3 in. in height, and with a growth of 17 in. at 3 ft. from the ground. I have, unfortunately, no record of the date of planting, but, as it was purchased soon after its first introduction by Messrs. Veitch, it cannot be less than twenty years old. It is planted on a sheltered bank of the old red sandstone, in a soil and aspect highly favourable to growth and protection; it is in fine condition, making a good annual growth, the bark of the stem clear, smooth, and healthy. Hitherto, I have been unable to discover a single perfect seed among the numerous "burrs" which it bears annually; nothing but the empty husks of a miniature Chestnut, about the size of a Pea, is to be found. On a still day this tree, with its small, glossy leaves, might well be mistaken for an evergreen Oak, but if there be any wind the waving branches reveal the powdered-looking, golden under surfaces, from which it has acquired its specific name. I have failed to meet with it in the collections I have visited, though I have often heard of its having been planted and having died. I should be glad to hear of any place where it has succeeded, with dimensions, &c.; perhaps some of your readers may be able to give an account of it as it appears in its native habitat. The description of it in Nuttall's supplement to Michaux's "North American Sylva" is meagre and uncertain. He states, that it grows from 20 ft. to 70 ft. high, that its leaves are 4 in. or 5 in. long (here, they are little more than half this length), and that it is said to be common at the Grand Rapids of the Columbia. He did not meet with it himself, and he says that the species rests entirely on the authority of Douglas. It is a tree well worth growing, but from its apparent rarity I should suppose either that it had not attracted the attention of arboriculturists to any great extent, or that it was difficult to please in the matter of soil, aspect, &c. It has been planted here sufficiently long to prove its hardiness, and now, after a severe frost, it seems in as good condition as before.

DUCIE.

Tortworth Court, Gloucestershire.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS

Beeches and Underwood.—To my last note (Vol. XIV., p. 579) allow me to add that I find large old Yews and Hollies growing close to the bole of very large Beeches, which must have been planted contemporaneously. In many cases Rhododendrons are close to the bole, 6 ft. or more high, and they might have been much higher, but they are topped over every year for game cover. These may be seen near the carriage drive from Kelso to Floors, yet "J. S. W." says he knows the Floors estate well, and informs us that there is no such thing there as underwood under Beech. As for the Ivy, Laurel, and Portulaga, they are quite as thriving, but the rabbits eat these in severe weather.—HENRY KNIGHT.

—Beeches grow here plentifully, and under the greater part of them there is not a vestige of underwood, but in one of the woods there are a good many Beech trees, under which Holly has formed a good underwood, growing luxuriantly and healthily. I may add that the Hollies are growing close up to the trunks of the Beeches.—J. JEFFERY, Ross Carbery, Co. Cork.

—Most of the writers on the practicability of planting shrubs and other plants under Beech trees seem to ignore the fact that Beech trees, when in a cultivated form, often grow on soils widely different from each other, and only occasionally in the kind of soil which they would prefer if in a state of nature. When in the latter position, on the dry chalky downs of the southern counties, a sort of a wild, disorderly shrub called the Way-faring Tree is often associated with Beech trees and Beech scrub. It is, I believe, a *Viburnum*; its foliage has a downy appearance, and in a mixed plantation, where Beeches occupy the same position as other trees on a soil at variance with that above alluded to, the undergrowth does not differ much from that growing under other trees; and I have seen the surface covered in spring with a dense bed of the bright-foliaged and equally bright yellow-flowered Pilewort. At other times a sort of short

wiry Grass takes possession of the place. The Rhododendron is not often found under Beech trees; not that the roots of the Beech are more pernicious than those of Elms, but the Beech is seldom planted on soils suitable to the Rhododendron, the latter associating more with the Birch and the Scotch Fir; and amongst them I have seen Rhododendron seedlings struggling successfully with the long Grass and coarse herbage and succeeding in attaining a large size, but I should doubt if any one ever saw the Rhododendron reproducing itself under Beech trees growing on a chalky subsoil. Possibly amongst shrubs the different species of *Rhus* might succeed better than most other plants. The *Acouba* usually thrives as well as most evergreens under trees, but I have seen young Yews spring up under trees of all kinds on a moderately dry soil, while on a stiff one Hollies often do better; and Mr. Thomson (p. 571, Vol. XIV.) is right about Ferns thriving up to the very collars of Scotch Firs, but the soil must have been congenial. I have also seen a Scotch Fir plantation almost overgrown with *Pyrola uniflora*; a *Plane* often grows in wet clays than in the usual dry habitats of the Fern. Bulbs of many kinds growing freely underneath trees and bushes are the exception to the rule. I once knew a plantation of Coppice wood (mostly Hornbeam) which resembles Beech very much. The soil was of a medium character—not very dry nor yet very wet—and that was so densely grown over with *Dafodils* that it was called "Dilly wood" by the country people; and I know of a meadow or rather a Grass orchard where the Snowdrops prevail to such an extent that they have to be mown over in spring, otherwise they would spoil the Hay. The character of the soil, therefore, ought always to be taken into consideration where planting either under trees or in open situations is contemplated.—A RETIRED GARDENER.

—Having lived in the immediate vicinity of large Beech woods for some years, I can most positively assert that, as a rule, no underwood will grow beneath their shade. In the centre of the large woods the ground is perfectly bare. If the trees are rather thinly scattered, Brambles will grow pretty freely, and just at the edge of the wood there is generally a fringe of Maple bushes intermixed with a few Ash saplings, but in the centre of a wood of any size, or under the shade of a large Beech tree even in the open park, it is not much beside the mark to say no underwood will grow. Two local terrestrial and parasitical *Orchids* grow freely very often beneath the shade of Beech trees, namely, *Serapias grandiflora* and *Listera Nidus-avis* (the Bird's-nest *Orchid*). *Monotropa Hypopitys* (the yellow Bird's-nest) is also generally to be found in a Beech country, and in our Buckinghamshire and Hertfordshire woods the pretty little Lesser Winter Green (*Pyrola minor*) is often found. Its roots creep like *Twitch* for yards amongst the flint stones, of which the ground is full, and it always dies when transplanted into the garden.—H. HARPUR CREWE.

—Mr. Knight's instance of underwood thriving and flourishing under Beeches, turns out exactly as I expected. Ten years ago he tells us "it was generally thought (at Floors) that nothing would grow under Beech trees," but at that period Mr. Knight began to plant under them, and has continued to do so down till last year, when he planted 2000 large Rhododendrons "on bare spots under Beech trees," and these, and others planted previously, he offers to show as proof that underwood will thrive in such situations. Testimony of that kind, however, throws no light on the subject, as few are so inexperienced as not to know that what underwood can be kept up under Beeches by planting it there as often as may be needful, but it in no way alters the fact that while underwood can be grown successfully in plantations of other trees, and, indeed, springs up contemporaneously with the same, and maintains its existence, it simply perishes before the growth of the Beech. As to the exception at Alderly Park, like "Cambria," I was much astonished to hear that Rhododendrons not only thrive amazingly, but flowered equally well, and even seeded under the Beeches. Of this, we shall, doubtless, hear more by-and-by.—J. S. W.

—The preponderance of evidence on this subject appears to be against shrubs of any kind thriving under the Beech. We have here some fine Beech trees, under which green Hollies thrive equally well, to all appearance, as in open places. These Hollies are from 8 ft. to 10 ft. high, and so dense in growth as almost to hide from view the trunks of the Beeches, and many of them are growing within 1 ft. of the base of the tree. They have not been planted by hand, but have evidently sprung from seeds deposited by birds, or some other agent.—J. ROBERTS, Gunnersbury Park Gardens.

—Having had some experience in planting under Beeches, I have come to the conclusion that it is a waste of time and money. The underwood may look all right for a time, but the hot, drying weather in summer kills it. If, however, it were planted close to the Beech before the latter had filled the surrounding soil with roots, it might grow, for then it gets below the roots of the Beech, the latter being a surface feeder, and this moisture is obtained from below, but

if the underwood be planted on the top of a mass of roots it will die. I last year cut down Portugal Laurels that grew quite up to the branches of a large Beech, and within 3 ft. of its trunk. But they were very old, and, I have no doubt, were planted when the tree was young. We have Beeches, too, that have scarcely a particle of vegetation under them. Our soil is very suitable for the growth of Rhododendrons, being composed chiefly of sand and peat.—H. CANNELL, *Felthorpe Hall*

—It would hardly be fair to presume that "North Hants," in his attempt to grow Rhododendrons under Beeches, merely had them planted without previously preparing for them some suitable compost to give them a start. This I consider the most essential portion of the work if we are to be successful. What plant is there that we could expect would flourish on soil already exhausted from supplying the requirements of a forest tree. As I am situated in a locality unfavourable to the growth of the Rhododendron (our sub-soil being rock marl, with hardly an average depth of 10 in. of soil), I cannot invite "North Hants" to come and see these shrubs growing under Beeches, but I could show him masses of the Spurge Laurel growing under them. Still, notwithstanding the natural unsuitability of our soil, we have now beds of Rhododendrons, also of *Kalmias*, *Andromedas*, *Ledums*, &c., all flourishing, but to obtain these results the amount of labour has been considerable, much more than that which I ever experienced in establishing Rhododendrons under Beeches.—A. HOSSACK, *Ragley*.

A CURIOUS ASH.

THE accompanying engraving represents a very singular variety of the Ash, of which two trees exist at Remilly, not far from Metz.

Fraxinus Remillyensis.

M. Carrière has named this variety *Fraxinus pendula remillyensis*. The two trees are nearly close together, and very much alike. They are not less than 65 ft. high, with trunks about 6 ft. in circumference. With the exception of three branches, the tree figured is of pendulous habit. The leaflets on the pendulous branches are broad, and generally very much like those of the ordinary weeping Ash, whilst those on the erect branches are narrow, very taper-pointed, and of a

deeper, more glossy green. As may be seen, the erect branches spring from pendulous ones; it seems to be a case of partial reversion. W. B. HENSLEY.

NORTH AMERICAN WILLOWS.

PROFESSOR C. S. SARGENT, Director of the Botanic Garden of Harvard University, Cambridge, Mass., informs us that cuttings of the following North American Willows can now be supplied by mail to the correspondents of that establishment. They have been grown and determined by Mr. M. S. Babb, of Illinois, who has devoted many years to the study and collection of the genus *Salix*. Applications, indicating by number the species or varieties desired, should be received before February 1, 1879.

Mr. Sargent will be glad to receive cuttings of other Willows, including all Asiatic species and forms, in exchange.

Elongation of Tree Trunks—The statement (Vol. XIV., p. 579) from the "College Quarterly," that "the popular notion that the trunks of trees elongate is entirely erroneous" requires qualification. Although they do not elongate by ordinary growth, in many trees, especially Beech, when a double or triple fork takes a vertical direction, the arms eventually meet forming a single stem. I can show several which are doing so. In one the trunk is about 6 ft. longer than it originally was, or rather, the fork is 6 ft. higher up; the lower 2 ft. have thoroughly banded, there being but a slight seam visible; the upper 4 ft. have united; but it will be many years before they have become one perfect stem, although they doubtless will, should nothing happen to the tree.—C. E. ISHAM, *Lansport, Northampton*.

Pyrus sinensis.—This sub-evergreen is well worth planting as a spring-flowering park tree. Its foliage is large and glossy, and it is a strong grower. Its fruit, I believe, is worthless.—G. B.

Cornus Mas aurea elegantissima.—Amongst variegated deciduous shrubs this is quite a gem, its rich and varied tints being hardly inferior to those of some of the best variegated stove Crotons. It is a new plant, and as yet rather expensive, but, being really good, it will be sure to give both pleasure and satisfaction.—G. B.

Holly Berries.—These are scarce this winter: they are now nil. The fieldfares and other birds have made a clean sweep of the lot. Old berries and young have all disappeared, and seldom has a white Christmas been so little relieved by scarlet berries or colour of any sort. Should the present severe weather last, the birds will have a sorry time of it soon, for Hips and Haws have all disappeared, as well as the Holly berries; even Acorns, which were almost the only fall crop of the past season, are going fast under the combined onslaught of the pheasants and the pigeons, which have crowded the woods in swarms for the past eight days after the Acorns.—D. T. FISH.

ROSES.

NOTES BY AN OLD ROSARIAN.

As these papers are written for amateurs (meaning by that not amateur exhibitors, but for those who love the Rose, and who value it for its own sake, and not for the honours it may bring them), I must say that the manner in which it is grown is too often neither creditable to the possessor nor fair to the flower. Here is the character of Rose growing as I have seen it over and over again. There is probably a Grass plot or lawn, or whatever term it may be dignified by; around this a piece has been dug out of the soil at intervals; in this has been planted a row of tall standards, which are elegantly supported by green stakes, and on the top of this standard is, or was, a head of some 2 ft. or 3 ft. in diameter and a fair amount of bloom. But is there any beauty in a standard Rose tree? Is this the most graceful way in which the loveliest of all flowers can be grown? Are green mops the perfection to which skill and patience can bring our Roses? There is but one place in which they are to my mind tolerable, and that is where a Rose border is made, and they occupy the back row; the front rows then hide the stock on which the Rose is budded; but to place them in a small garden and in a place where they are fully in view is surely subversive of all principles of good taste. But then there is another drawback. The owner has, perhaps, noticed at Rose shows some remarkable blooms, and, of course, he must have the best, and equally, of course, he does not stop to consider whether they are strong-growing varieties or not; and so he gets home his Marie Baumann, Marquise de Mortmarte, or Mademoiselle Marie Cointet (for he could never think of ordering anything but Hybrid Perpetuals), and is surprised to find that, instead of getting larger, the heads of the plants diminish in size until they have vanished altogether. Blanks are left, the beautiful regularity is spoilt, and a whole year must be spent before the row can resume its regular appearance. Another favourite plan is to have a round bed with some half-dozen standards planted in it, and some annuals sown in the soil beneath. This is often done in the front gardens of villa residences, where it is as much out of place and in as little harmony with the surroundings as a huge Deodar (which one often sees) filling up the entire space and darkening all the front windows of the house. Then there are other Roses scattered throughout the grounds, sometimes stuck in the middle of a clump of shrubs, sometimes arranged in beds with other plants. Have I not before my mind's eye now a lovely (?) arrangement which I saw this last summer—a bed of dwarf Roses, and planted in amongst them, of all things in the world, some Chilean Beet? I was certainly not asked by the lady who showed me the garden to admire this, for she pointed it out as an example of the taste of her gardener, in whose hands the arrangement had been left. When dwarfs are grown, I have over and over again seen what seemed to the owner as flourishing bushes, but of which the complaint was sadly made that they did not flower. Nor was this to be wondered at; the poor Rose had long since departed, and the Manetti stock had flourished vigorously, as it always does, and the wood, not being so distinct in its appearance from many Roses as the Brier, the result is as I have indicated. Then no attention whatever is given to the aspect in which the Roses are planted; sometimes it is a bleak and windy spot in the garden, where they are well-nigh blown out of the stocks; sometimes in a dreary border, where the sun never reaches them until late in the afternoon; sometimes in a dry and arid spot, where they are left to shift for themselves and never mulched or watered, and yet their owners are very much astonished that they cannot grow Roses such as Messrs. Paul, or Cant, or Baker, Jowitt, or Hole exhibit at the Great Rose tournaments. As well might an ordinary farmer, who does not stall feed, groom, or carefully house his cattle, complain that his beasts are never so fine as those which he sees exhibited at the Smithfield Club show. None of these results can be obtained without a great expenditure of money, time, and anxiety, and it is unreasonable to expect them without it; but, at the same time, Roses of nearly equal size and beauty may be grown, if attention be given to some of those points which are essential to the well-being of the Rose. There

is one fact which it may seem ungracious to notice, but it is true, for all that, that it is utter waste to attempt to grow the Rose where it comes under the influence of smoke. Many and fruitless have been the attempts to overcome this, and yet wifal people do not like to think that they must give up their favourite. Do I not remember how my friend G., who had been living in a cool and open spot, where his Roses flourished well, on removing near a large town, persuaded himself—Ah! it is not like London, and my dear Roses need not be given up. They were removed tenderly and carefully planted, but, alas! do what he would they obstinately refused to grow; they missed the gentle zephyr which used to come and woo them with pure and sweet breath, and the dew distilled in all its purity on every leaflet. Instead of it, clouds of poison-laden vapours swept over them; fierce breezes, that whistled through long rows of houses, caught them; they shrivelled up under these baneful influences, and when I saw G. last, the Roses had all gone and scarlet Pelargoniums had taken their place.

What advice, then, can I give to the lovers of the Rose whose ambition it is to have a few good Roses, and who also wish for variety in their gardens? I would, in the first place, strongly recommend the rejection of all standards; independently of their ugliness, there are other reasons which I think should insure their rejection in small gardens; the sap has to travel a long way up, and unless they are in thoroughly good Rose soil, which is not very often the case in small gardens, sufficient nourishment is not conveyed to the scion, and hence feebleness and death take place, and a gap amongst standards is more noticeable than amongst dwarfs, amongst which, too, deaths are not so likely to take place. Then as they do not throw out so many shoots, unless they are very carefully watched the worm in the bud attacks them and the bloom is destroyed; doubtless hand-picking will remedy this, but it is not everybody who can spare the time for that, and as regards abundance of bloom, as a rule, we must claim it for dwarf Roses.

Then, I would say, be careful as to the position you choose for your Roses, and, if possible, give them a place to themselves. I do not mean a Rosery, a grand place with trellised arches and elaborate arcades, but even if it be only two or three beds, by all means endeavour to keep them to themselves. The Rose will not brook nursing with other flowers, and no real lover of it will care to see it lowered by a plebeian mixture. Even when we cut our Roses we do not care to see them mixed up in a bouquet with other flowers; we prefer putting them in specimen glasses or vases by themselves, wanting nothing but their own foliage to set them off. It must not be forgotten, too, that Roses suffer very much both from wind and frost; and hence, if a position can be given to them which is sheltered and, at the same time, not confined, it should unquestionably be done. Dwarf Roses do not suffer so much as standards from either of these foes; they are not so much exposed to the wind, and it is comparatively easy either to mulch the beds in frosty weather or to place some Fern or small branches of Spruce or Laurel amongst them; but they do not like a confined space; it generates mildew and Orange fungus. As it is not in every small garden that these requirements can be met, the best must be made of circumstances, and the spot most in accordance with these conditions chosen. I have seen as healthy and fine plants, and as good blooms, in some small suburban gardens as I have seen anywhere, and keeping these in view, and remembering the lamentable shortcomings I have seen in other gardens, I wish to show how it is possible for the lover of the Rose to enjoy his favourite flower. In my next paper I hope to enter on the question of stocks and soil, both very important elements in successful Rose growing.

DELTA.

Souvenir de la Malmaison Rose.—Can any Rose grower explain how it is that this fine Rose is nearly always malformed and comparatively useless early in the year, so many of the hearts being hard and green or black, while in the autumn almost every flower is perfect in form, and far more delicate and elegant in bud than it is early in the season? Can it be that there is an excess of vital force early in the year, and that, as this gets expended or used up, the buds get fined down, and the Roses grow into proper form? This rather receives confirmation from the fact that plants on strong soils are, as a rule, more grossly malformed than those on light and poor

soil, though it is seldom, indeed, that the earlier crops of *Roses* escape malformation, and equally rare to find imperfect flowers on the *Souvenir de la Malmaison Rose* in the autumn.—D. T. FISH.

FLOWER FORCING IN MARKET GARDENS.

HYACINTHS, TULIPS, AND NARCISSI.—The quantities of these forced every year are immense. One grower uses 160,000 *Hyacinths* and 10,000 *Tulips*, another grower 70,000 *Hyacinths* and 50,000 pots of *Tulips*, yearly, and others in proportion. The bulbs are all, of course, imported from Holland, and as soon as they are received in autumn they are potted into 6-in. pots, placed in square beds out-of-doors, and thickly covered over with cocoa-nut fibre; this, being light, can easily be removed, so that the most forward bulbs may from time to time be selected as required for forcing. Good growers always endeavour to send a few dozen pots of *Hyacinths* to market the day before Christmas. There is then a ready sale for them at good prices, sometimes as much as from 20s. to 30s. per dozen being paid for them. For this purpose the bulbs are placed in a gentle bottom-heat in a warm and partially dark house until their flower-heads show themselves, when more light is gradually admitted until they are subjected to every possible ray that can be secured. In this way successive batches are continually being brought on until the end of April, after which time *Hyacinths* are nearly over.

Tulips are placed in shallow wooden boxes, and in these they remain until their flower-buds can be seen, when they are lifted and potted, four or five in 5-in. or 6-in. pots, using good sandy loam for the purpose. The sorts of *Tulips* principally grown are the scarlet, rose, and white *Van Thols*, the yellow *La Pluie d'Or* or *Golden Prince*, and the common single *Van Thol*.

Roman Hyacinth.—This charming early-flowering plant is largely grown by nearly all market growers. The bulbs are imported from France, Holland, and Belgium; and in some seasons, when Continental growers anticipate a larger demand for roots than the supply is well able to meet, very high prices are often demanded for them from English growers. Notwithstanding this, they are extensively cultivated, and invariably realise good prices in Covent Garden, their sweet-scented, pure white blossoms being so much sought after just at a time when good flowers are comparatively scarce. There are few bulbous plants that will bear rapid forcing better than this *Hyacinth*, and few that better repay the little trouble which they incur in bringing them into bloom. From the end of October to Christmas there is always a good sale for *Roman Hyacinths*; and any one visiting Covent Garden at that time of year may see large vases and glasses full of fine large spikes of flowers, waiting to be consumed in the making of bouquets and other floral devices. Another kind closely allied to this *Hyacinth*, and indeed one that may be termed a blue-flowered form of it, is grown as a succession crop, but coming in as it does a month or so later, and the blossoms being coloured, they do not fetch nearly so high a price as the white ones. *Roman Hyacinths* are brought on in successional batches, the bulbs being put thickly in boxes as soon as imported, and placed out-of-doors under a 6-in. covering of spent Hops or Cocoa-nut fibre. When the shoots are 2 in. or so in height, the boxes are removed, put into a little warmth, and snowy flower-spikes come up directly.

Narcissi.—All kinds of these are grown extensively in orchards, near old walls and in other bye- corners, and

their blossoms are always desirable; amongst the many kinds that find their way to market, none are more beautiful than the *Paper-white Narcissus* (*N. papyraceus*). Its flowers are produced naturally in February and March, and, being small and of the purest white colour, they are highly esteemed for bouquets and other decorative purposes. The *Pheasant-eye Narcissus* (*N. poeticus*), too, is very pretty; it comes in later—say, about the first week of April; but then flowers are getting plentiful, and it is not so much thought of as it would be were it produced earlier in the season. After this comes its beautiful double variety. Immense bunches of both kinds may be seen on the stalls, and in market women's baskets, &c., and are suitable for those who trade in second or third-class flowers. Great piles of the common yellow *Daffodil* of our woods may be seen at every turn in the market in spring, as well as the choicer kinds of our gardens. The latter generally come from places where the bulbs are grown in quantity for sale. Most of the bulbs of the *Narcissi* which are forced are imported from Holland; they are chiefly grown to supply cut flowers. The *Paper-white Narcissus* is the first to bloom; then follows the double *Roman*, with five and six and more large double flowers on a truss; *N. gloriosus* comes in afterwards. The bulbs attain great strength during the time they are hidden from view under a heavy coating of rich fertilising material, and their blossoms are always in great demand. Immense quantities of flowers of *Narcissi* of nearly all species and varieties are supplied to Covent Garden from bulb nurseries, the removal of the blooms being said to benefit the bulbs, and the money obtained for them where large quantities are grown is considerable.

CROCUSES.—These are not forced in very large numbers but are grown extensively between fruit trees. They are planted on raised beds of good rich soil, and when they come into bloom are lifted in little clumps, their roots tied in Moss, and placed in boxes for market. The common yellow, blue, and white are the kinds principally grown, and to see the beds—which sometimes occupy more than half an acre of ground in one place—in full bloom is a sight better imagined than described.

LILY OF THE VALLEY.—Few flowers are more universally admired than the *Lily of the Valley*, and few are more remunerative to the grower when he can get a ready sale for them. The earliest plants are usually got into bloom about Christmas, when good potfuls sell retail for 10s. 6d. each in the market. For this purpose single imported crowns without any earth adhering to them are used. These are selected by the Belgians and Dutch, who grow them extensively; and all are warranted flowering crowns. A large quantity of these can be packed in a very small compass; therefore the freightage costs but little, and the roots themselves, when bought in quantity, are very cheap. These are placed as soon as received in strong bottom-heat, and when nearly in bloom they are potted, together with a few roots grown for their leaves, in 5-in. pots; they are well watered, and, after being hardened off a little are taken to market. Sometimes, however, the rapid forcing causes them to come "blind;" but good, plump-looking crowns can generally be trusted. Ferns are sometimes mixed with the bulbs in potting, and sometimes the beautiful blue-flowered *Scilla sibirica* is employed with good effect. Some growers force *Lily of the Valley* early for cut blooms alone; and where they can sell all they grow, this plan is perhaps the most remunerative, as at Christmas single sprays fetch from 6d.

to 1s. each. Later supplies are grown from imported clumps, which contain from twelve to twenty buds; these are potted in 5-in. and 6-in. pots, and placed under cover, a quantity being introduced at a time as required. Market gardeners always put as large clumps of crowns of Lily of the Valley as possible into the pots. If they come up well, and the shoots are too thick, all superfluous shoots are removed when they are about 3 in. high and have formed their flowers. As many roots as possible are obtained with each shoot so removed, and six or eight of them are potted together into other pots. A little soil is placed on the surface of the pots from which they were taken in order to fill up the vacancy, and the whole is placed in warm quarters to develop their flowers and leaves perfectly. The thinnings never make good plants; on the contrary, they fail even to make a single rootlet; but the sole reason for potting them is that they produce a few sprays of cut bloom, which, early in the year, fetch high prices, and it being found that as much money can be obtained from a moderately well-filled pot as a thickly-filled one, thinning of the crowns becomes a profitable practice. One grower uses as many as 6,000 clumps of Lily of the Valley yearly, in addition to several thousand single crowns imported free of earth. Indeed the weight of roots used by him every year exceeds four tons. Outdoor flowers of Lily of the Valley brought to market from the country are generally green and poor compared with those produced either early or late on imported plants. The method of growing Lily of the Valley adopted by the Dutch growers is somewhat different from that practised near London. They dig up single crowns and tie them up in bundles of ten or twelve together, and plant them in a soft loamy soil, well manured with cow manure, at a distance of 10 in. or 12 in. between the bundles, in a shady position. The plants are not disturbed for three years, when they will be found to have formed good clumps. Plants thus treated, are remarkably well adapted for forcing. For this purpose they are planted in pots of suitable size, covering the crowns with an inch or two of soil, and then the pots are plunged for about a fortnight in Cocoa-nut fibre. By that time they will be well rooted. The pots are then plunged in Cocoa-nut fibre in a hot-house, covering them to a depth of 5 in. or 6 in. They remain there until the plants appear above the surface of the fibre, when the pots are taken out and put for a few days in a warm place, after which they are removed into a light house to expand their flowers. C. W. S.

A WINTER GARDEN.

A VERY suggestive illustration of what is possible in a winter garden, scarcely differing from an ordinary building, may be seen in the private gardens of the Emperor at Vienna. There an enormous building with only one side (and that not wholly) of glass is planted as a winter garden, and the effect in some respects is superior to anything of the kind to be seen elsewhere. The main lesson, however, that the building affords is in showing how far it is possible to make a beautiful winter garden in a building which is not a glass shed, and which, therefore, allows of the usual architectural treatment. Generally, the most successful winter gardens are those wholly of glass, and we have recommended such as the only satisfactory means of securing a healthy growth and satisfactory results therein. The conservatory in the Botanic Gardens in the Regent's Park may be taken as the model of a good house for the purpose alluded to. Unlike it, the winter gardens we allude to, however, are those in which tubs and pots do not appear, in which the vegetation is planted out, and a natural and artistic effect sought. All those that we have illustrated in

THE GARDEN were houses of this kind. The Vienna winter garden is quite as graceful as any of them, with this difference, that nearly all its plants are out-of-doors during the summer. It is, in fact, an immense "Orangery," in which a large collection of plants is stored in the most graceful and natural way imaginable, with devious walks, little carpets of turf formed of Lycopodium, Tree Ferns, giant Dracaenas, with Ivy festooned naturally among them, and Ferns in abundance. Apart from the question of winter gardens, this points to the fact that we require more courage as regards embellishing semi-lighted places with plants, not for a day or a week, but a season. Numbers of subjects that make their growth in summer, whether in or out-of-doors, would not suffer in the least from being grouped in imperfectly-lighted positions, always assuming that a suitable temperature was maintained, and that they were not exposed to injury from gas.

PLATE CLVIII.

STOBÆA PURPUREA.

This is a member of a numerous genus of South African Thistles, or rather Thistle-like plants, for they are more nearly related in floral structure to Senecio than true Thistles. Many of them are exceedingly handsome and noble plants, and *S. purpurea* is perhaps the finest of its genus; but in spite of their ornamental character, few of them have been introduced into our gardens, and those which have have found little favour. This is probably due to the fact that they are scarcely suitable for indoor culture, and to grow them in perfection in the open air some little attention is required, as they are not perfectly hardy. *Stobæa purpurea* is, however, one of those plants which recommend themselves to the genuine lover of flowers. In its native haunts, in the valleys of the Winterberg, Mrs. Barber found it growing in large patches, many thousands of plants growing close together, as if they had been planted in beds, and making a very imposing show. Like our less showy Thistles, then, it is of a gregarious nature, and it is very effective in masses, though single plants in a mixed border are equally prominent. In a wild state it grows from 2 ft. to 3 ft. high, and doubtless in a rich soil it would grow higher. Nearly all the *Stobæas* have yellow flower-heads, but our plant has them of some shade of violet, purple, or lilac, and in the Kew Herbarium there is a specimen of a variety having pure white flower-heads. In Bentham and Hooker's "Genera Plantarum," *Stobæa* is referred to Berkheya, forming together a genus of upwards of seventy species, all, except one tropical African, natives of South Africa. *Berkheya grandiflora*, a fine yellow-flowered species, was formerly in cultivation, and a figure of it appeared in the "Botanical Magazine," t. 1844; and in the same volume, t. 1788, there is a figure of the comparatively insignificant *Stobæa pinnata*. This is the first publication of a coloured plate of the handsome *S. purpurea*, which flowered in Mr. Ware's nursery last summer, and which was introduced into this country a few years ago by Mr. Wilson Saunders, through the agency of Mr. McOwan, of Yale College, Somerset East, South Africa. W. B. HEMSLEY.

Cupania filicifolia as a Specimen Plant.—This makes a handsome specimen plant, when well managed, for the decoration of the stove or warm greenhouse. It grows freely under liberal culture, and retains its graceful lace-like leaves down to the base. Old plants of it, cut down and allowed to push up a single shoot, soon develop into handsome specimens. We lately saw some which had been thus treated in the Victoria Nursery, and which are now from 6 ft. to 8 ft. high, and well furnished with foliage down to the pot. This plant is here very successfully propagated (a somewhat difficult operation as a rule), and grown into neat little plants for table decoration.—S.

Cycas intermedia.—This noble plant is much better adapted for the decoration of the conservatory than any other *Cycas*. Its leaves are long and graceful, of a pea-green colour. It is also said to be harder than *C. circinalis* or *C. revoluta*, and, being less stiff and formal in habit, it is preferable to either of them. I lately saw fine examples of it in Mr. Williams' nursery at Holloway.—S.

GARDENING FOR THE WEEK.

Stove.

There is a considerable difference between the stove proper—that is, the house devoted to heat-requiring plants, wherein a sufficient temperature is kept up to preserve in a growing healthy condition those that come from the hottest regions, of which, for example, may be taken *Ixoras*, *Dipladenias*, *Combretums*, *Crotons*, *Anthuriums*, *Artocarpus*, *Diefenbachias*, *Marantas*, *Nepenthes*, *Pandanus*, *Cyano-phylums*, *Spherozygnes*, and many others of similar nature—and the intermediate house, where a temperature is maintained enough for such plants as do not require quite so much heat as the genera already named, but yet need keeping considerably warmer than true greenhouse plants. It often happens that an attempt is made to keep through the winter plants that at all times of the year need a high temperature, in houses where really no more heat is at command than is requisite for intermediate subjects; the result of this is, they are, during the winter season, so checked that the spring is far advanced before they get into a decent healthy growing state, making comparatively little progress, and, in the case of plants grown for their flowers, producing a correspondingly small amount of bloom. In place of this I have always found it best, where there is not the means of keeping up sufficient heat, to confine the cultivation to those plants that do not want more than an intermediate temperature. The stove should now for some weeks be kept in the night at from 65° to 68° or 70°, according to the state of the weather, with a rise by day of 5° or 6°. Frequently, when it is clear and sunny, the thermometer will for a short time run up a few degrees higher than this. The intermediate house will do some 10° lower, day and night.

Fermenting Material.—Nothing is more conducive to a healthy growing atmosphere than a good body of fermenting material present in the stove, independent of whether it is the practice of the cultivator to plunge the greater portion of the plants, or only such as bottom heat is found indispensable for. With this view the requisite quantity of tan, than which nothing is so enduring in the heat it keeps up, or leaves, if they are used, should be at once got in. In clearing out the old material care should be taken to remove the whole, so as to get rid of worms, that are almost certain to have more or less got possession of it, and from which they find their way to the balls of the plants, and do much injury. Advantage should be taken to hot wash the inside of the pit as well as all other brick-work surfaces in the house, also to give a thorough cleaning to the glass and woodwork, by which the greatest possible amount of light will be admitted to the plants. Where the heating power happens to be deficient, a considerable body of tan, as already described, will, in a short time from its introduction, increase the temperature of the house several degrees, and maintain such until the weather is warmer by the increase of sun-heat.

Ixoras.—Any plants of *Ixora* that were not cut back after flowering in summer—which is much the best time for the operation—if there appears a likelihood of their getting into a too straggling condition before the end of the season, may be shortened back; but in doing this it must be borne in mind that it will a good deal delay the time of their blooming. Where several of a kind are grown, if a portion be thus treated, a succession will be secured.

Dipladenias.—These, when they have attained sufficient size and strength, should be freely cut back every year, reducing the shoots (almost like what is done in ordinary Vine culture) to a little beyond the point to which they were shortened the preceding year.

Bougainvillea glabra.—This, the most useful and manageable of the genus, should be started early, by which means it will flower two or three times during the season. In pruning it, it is better to remove the weak shoots, retaining those that are sufficiently strong to push stout blooming growths. If the plants have been, as they ought, well ripened up and dried off by withholding water at the roots until the leaves have fallen, they should now be thoroughly soaked in a tub or bucket containing as much tepid water as will admit of the balls, pots and all, being immersed for twelve hours; this is far safer than simply giving water in the ordinary way, which is often so deceptive as to only moisten a portion of the soil, in which case they break weakly, the cause often not being discovered until a good deal of time is lost.

Allamandas should be at once cut back in the case of full-grown specimens, removing, as with the *Dipladenias*, the greater portion of the preceding summer's shoots; for if too great a length of these be left, the plants get crowded with useless wood. I have found it best, when these plants have attained their full requisite strength, to re-pot at the time they are pruned, as in this case they require so far shaking out as to necessitate disrooting to one-third or

one-half the whole extent of the previous season's formed roots; and if this be not done until the plants have broken into growth, a considerable portion of the young shoots started will not make further progress. As they, like the *Bougainvilleas*, will have been allowed to get quite dry at the root, they should be similarly soaked before potting, so as to insure the whole of the soil being moistened. *Allamandas* grown as roof climbers should be in like manner cut back, in extent according to the size they have attained, and the space they are required to cover; and, if planted out, must have some of the surface soil removed and replaced with new, to which a good quantity of manure has been added.

Shrubby Clerodendrons.—These, including the different kinds of the *C. fallax* tribe, should, in the case of old plants, be well cut back, reducing them to 1 ft. or so above the collar, otherwise they get naked and unsightly. Previous to pruning, let the soil get comparatively dry, keeping it in this condition until they have broken freely.

Gloxinias.—By judicious management, these may be had in flower for a considerable portion of the year, and when treated in the manner that gives them the stout, robust character which admits of the flowers standing satisfactorily in a cut state, they are most useful for this purpose. With this object, a few of the tubers earliest put to rest may be started, shifting them into not too large pots, and, if possible, putting them on a shelf or other position where they will be close to the glass, as upon their having all the light possible depends the full amount of usefulness being secured, either for general decoration or for cutting, as already alluded to.

Gardenias.—If the plants have been well cared for the preceding season, and are clear from insects, they will furnish a long succession of flower through the spring, keeping them well up to the glass, by which means their advancing buds will be much less likely to drop off—a circumstance that frequently occurs when they are subjected to a good deal of heat, with a view to getting them on early.

Pentas carnea and P. rosea.—These continuous and free-flowering subjects, if well attended to and grown in moderate warmth, will keep on flowering from every bit of growth they make.

Bouvardias.—Where sufficient plants exist, and there is the convenience of keeping them in different temperatures, a portion should occupy the lightest position in the stove, with their heads close to the glass, as upon this, like many other winter-flowering stove subjects, depends their ability to endure when cut. If well-grown plants with strong shoots are secured, these, by keeping thus warm, will continue making growth and bearing flowers for a long time, as, when the bloom produced from the leading portions of the shoots has been cut away, they will keep on breaking from the lower eyes, in this way yielding a succession.

Plumbago rosea and Eranthemum pulchellum will, if the plants have been strong, continue producing flowers from the weaker growths after the leading shoots are over, and will be benefited by a little weak manure water.

Intermediate House.—Where the means do not exist of keeping the warmest plant house above an intermediate temperature, such operations as the foregoing should be delayed for some weeks yet, so far as the shaking out and potting of any plants go, inasmuch as these matters should not be carried out until there is enough heat to at once excite growth.

Destruction of Insects.—In plant growing there is no such thing as an immunity from insects, as, with the utmost vigilance, some of the less objectionable kinds are certain to be troublesome from time to time; and with the most injurious species, such as mealy bug, where these exist it is impossible to keep any collection of plants, large or small, in a condition that will give the best results in general appearance and the quantity of bloom they produce, without either absolute extermination, and afterwards the greatest care, so as not to introduce affected plants amongst the stock, or by continual application to keep them so thinned that the injury they inflict will be reduced to a minimum. As it is at this comparatively dormant period that insects can best be coped with, it may be well to remind those in charge of collections of plants, that the hours spent in the destruction of these pests at this time will be more effectual than a corresponding number of days when the season is further advanced and their increase much greater. Whatever insecticide is used, it should be such as admits of the whole of the affected plants above the soil being dipped or syringed with the liquid so as to reach every part, bark and leaves. I have no faith in any but liquid applications for the worst descriptions of insects, such as bugs and scale, as with anything in the form of dust or powder there is no certainty of its reaching the whole surface of the plants; neither are such liquids that do not admit of being used in sufficient quantity to get

to every part of the affected specimens of any good except where there happens to be only a very few small plants infested, as their use involves too much labour and uncertainty. Where anything like an attempt is to be made at complete eradication, not only should those plants that are known to be affected be subjected to the cleansing process of immersion or syringing, but every plant, large or small, on which the insects can find food or shelter, should also be similarly treated, and the operation repeated continuously until there is something like a certainty of both eggs and mature insects being destroyed.

Forcing Pit.—Upon the sufficient size and right construction of this structure depends, in a great measure, the ability to keep up a supply of cut flowers now for some months where there is a considerable quantity required, for with such plants as are brought into flower in heat, through the winter more particularly, those that after the first production of bloom will immediately make successional growth and flower from it, unless this growth be made in a thoroughly light house, with the heads of the plants elevated as near the glass as they can be got, the bloom is certain to be worthless for cutting from its soft, flimsy character. It is through imperfect realisation of this that many winter-grown flowers receive an undeserving character for being of little use, when the fault rests in the way they have been grown and not in the plants themselves. The temperature kept up here should be from 65° to 70° in the night, with a rise of 10° by day, according to the weather.

Tuberose.—As these are brought on in succession, with a little bottom-heat if possible in the first instance until they have got their pots well filled with roots, they should be placed with the points of the shoots close to the roof, lowering them as they advance in growth. Do not over-water, but give sufficient to keep their somewhat moisture-impatient roots in an active condition. Withhold water altogether from the successional bulbs until it is certain that they have pushed a good amount of roots.

Lily of the Valley.—Bring in sufficient quantities of this to keep up the supply, plunging them in heat until the shoots have made considerable progress, after which expose them gradually but slowly.

Lilacs.—Where these are forced in quantity and there is no place where they can be kept perfectly dark in the way necessary to produce the blanched flowers, a few may be introduced to the forcing pit, but in all cases the plants should consist of such as have been previously prepared and grown on for the purpose, as ordinary bushes if dug up have generally an unsightly appearance, and bear little flower compared with their size. Where a forcing pit or house, such as here described, exists, and which is an absolute necessity where large supplies of winter-forced flowers are needed, and the object is to have them with the least expenditure of fuel and labour, as well as to obviate the unavoidable compromise in treatment that becomes necessary when brought on in an ordinary stove, the annual winter-blooming occupants, of which that may be said to consist of an annual growth prepared through the summer, will find their best and most suitable place here.

Hyacinths, Narcissi, and Tulips.—These, especially the two former, must be brought on in succession, but they require a cooler position than in the house under consideration.

Potting Soils.—The most successful cultivators of pot-grown plants at the present day are fully aware of the absolute necessity of selecting the best, and nothing but the best and most suitable soils for the requirements of the different plants they grow, without which it would have been futile to look for the high standard that has been reached; but, unfortunately, there are very many who do not to the full extent realise the importance of this, and follow the penny-wise course of attempting to grow their plants in any sort of material that is called peat or loam as the case may be. The greatest mistake is committed in respect to the former, by using any description of poor, worthless material, provided it comes under the name of peat, often of a close, black, hungry character, which, even if the plants appear to thrive for a time, has no lasting properties in it to keep the roots in the required healthy condition; hence the plants never attain the full vigour they are capable of, but go off prematurely. Nothing but the best peat selected and obtained from localities where such is to be had should satisfy the cultivator, and the same may be said as regards loam, only the latter can be had from many more sources. Anything less than this is simply a waste not only of labour, but also in the cost of fuel and the glass erections in which the plants are grown. As the time for potting many plants is fast approaching I could not give more seasonable advice to all desirous of growing their plants well than to procure those soils that are best adapted for the kinds which they cultivate.

Orchids.

East Indian House.—The temperature best calculated to meet the requirements of the many plants from different countries located here may be put down for the night at as near 60° for the next six or seven weeks as it can be got, with a rise of from 6° to 8° by day, according to the weather.

Saccolabiums.—Put these at the extreme warmest end of the house; they will not bear well such a lengthened drying up of the roots as the generality of *Aerides*. Care must be taken that they are not long kept so dry as to cause the leaves to shrivel to any appreciable extent, for should this occur, more of the old lower ones will turn yellow and fall off than is consistent with the ever augmented numbers and increasing size that healthy plants should consist of.

Aerides.—These, like the *Saccolabiums*, should be now at rest; their leaves, being considerably tougher and harder in texture, as well as the plants generally, they are able to bear a lower temperature than *Saccolabiums*, and can stand without injury a totally dry state of the roots somewhat longer; but if the plants have been grown under conditions of light, air, and a healthy, not saturated, atmosphere, they will show plenty of flower-spikes without too much drying up, and the temperature above indicated will not induce them to push flower too soon, or bring the bloom on earlier than required by those who may wish to somewhat retard it.

Vandas.—These will bear keeping dry for a time, but great care must be taken not to carry it too far, or the loss of numbers of the lower leaves is certain to follow. To this cause, coupled with the plants being grown under conditions that have made the leaves soft and deficient in substance, is directly attributable the unsightly naked state in which they are too often seen.

Phalænopsis.—Consisting, as they do, of little besides roots and fleshy leaves, an undue amount of drying at the roots is fatal to them, ever increasing in size, as is their wont, for when subjected to this, the loss of leaf at the base is generally equal to what they have made at the top during the current season, but though, as I have already urged with the preceding family of plants, the necessity for care in seeing that a totally dry condition of the material in which the roots are placed is not carried too long when water is given, it should by no means be applied in such quantities as to wet it to the extent requisite in summer during the time they are making growth, but just a little, so as to bring the *Sphagnum*, &c., to that state best described as being neither wet nor dry.—T. BAINEs.

Flower Garden.

Auriculas.—A grower of these, writing from the north, says, "My frames are covered with a thick blanket, and over that 1 ft. of snow;" and then he adds, "What shall I do with them?" The answer is, let them alone. If the pots are frozen, it matters little whether the frames are closely shut up or not. When the frost disappears, the plants should be looked over, and all decayed leaves removed. Only water the plants if the soil in the pots be dust-dry, but not at all during frost.

Carnations and Picotees.—The instructions given for *Auriculas* apply to these, but it is better not to allow the soil in the pots to become quite so dry as that of the *Auriculas*. Of course, it would be injudicious to water at all during severe frost. There will be a number of decaying leaves to be removed, and the soil in the pots should be pressed in a little, if loose.

Dahlias.—It is quite necessary to look over the roots. Decay frequently takes place at the crown. Such roots can be saved by placing them in heat—a very gentle, rather dry heat. It is almost too early to start any of the roots yet; but those who want a good supply of plants from a limited stock of roots will be making preparations for a start.

Gladioli.—Seedlings of these in pots may have been stored away with the soil quite dry, and, if such moisture as it contained has quite evaporated, the bulbs, being small, may not start; but if the soil contains moisture, they will. It is better, therefore, on the whole, to shake them quite out of it. The large roots keep well if each sort be wrapped up separately in paper, and stored in a dry place in a frost-proof room.

Hollyhocks.—Choice varieties of these, potted from the open ground two months ago, should be placed on a shelf in ainery or Peach house near the glass. Frost should not be allowed to get into the house, and if placed in a warmer situation, the shoots will be ready by the end of the month to be taken off as cuttings, or to be used for grafting on pieces of roots. The commoner sorts wintered in frames will be safe there for the present with a few mats thrown over the glass during severe frost.

Pansies.—These should be potted into their blooming pots early in the year, but this cannot be done unless the weather is fine. Soil should be prepared for them, and pots also should be in readiness. Pansies like a rich soil, and the best stimulant for them is rotten cow manure.

Pinks.—During frost these require no attention, except to see that rabbits cannot attack them. Make any plants thrown out of the ground by frost firm, by pressing them into the soil with the fingers.

Phloxes, Pyrethrums, Pentstemons, and similar hardy plants in beds, require scarcely any attention during winter. It is a good plan to place some dry manure on the surface of the beds, or a layer of leaves that have lain in a heap since autumn. It is astonishing how severe frosts may be kept out by a very slight protection applied to the surface of the ground.—J. DOUGLAS.

Hardy Fruit.

The late severe weather will have somewhat retarded operations in this department, and, therefore, some energy will be required as soon as a more favourable time sets in to bring up arrears of planting, pruning, nailing, dressing, and similar operations. In the meantime proceed with trenching, digging, draining, and soil carting, and so get the work forward as possible. If not previously done, Strawberry plantations should be "pointed" over, after which mulch them thickly with half-rotted stable manure. Of course, previous to the pointing remove all runners and decayed foliage, but avoid wanton destruction, for though some even recommend mowing off the old foliage the practice is not a good one. New Raspberry plantations may be made at any time between this time and the end of March, but the sooner the better, as such a plantation if well made will last for ten or twelve years. The ground should be deeply trenched and heavily manured, i.e., if the nature of the soil demands it. A good loam, inclining to adhesiveness, requires but little manure, but in light, sandy soils Raspberries must be freely manured if good returns be desired. The pruning and tying of established plantations should be done as soon as possible, after which well stir the surface, but do not dig it, and mulch with the best manure at command. In favourable weather Peaches and Nectarines should all be untied or unnailed as the case may be, and after carefully cutting out the long naked branches and superfluous shoots, well wash them with soap-suds, which is best done by means of the garden engine. If the trees, during the past season, have been badly infested with aphides, the most effectual preventive is to have the whole painted with a solution of Gishurst Compound, according to the directions accompanying the same. Apricots are rarely subject to the attacks of aphides or other insects; still, as prevention is better than cure, as soon as pruning and nailing are completed let these also have a thorough washing with soap-suds. Our trees a season or two ago were badly attacked with soft brown scale, which was entirely annihilated by means of the washing here recommended. Cherries, Morellos in particular, are very subject to the attacks of black aphids, and, therefore, strong measures should be taken to ward off such attacks; winter dressing of both walls and trees is, in such a case, imperative. Orchard trees, consisting of Apples, Pears, Plums, &c., may be greatly invigorated by judiciously thinning out any branches that cross or chafe each other, freeing them from Moss and Lichen by dressing them with quicklime or brine. As such work as this can be done in weather, so to speak, when nothing else can be done, any negligence in respect to it is unpardonable. Any trees that are old and worn out should in hard weather be grubbed up and the ground trenched preparatory to planting as soon as favourable weather arrives. Trees that are to be regrafted in March or April had best be headed down at once. All prunings and grubbed-up wood not required for fuel should be converted into wood ashes, which is an excellent manure for all kinds of fruit trees, and, indeed, for almost everything else. If a new orchard is to be formed, the first matter to be considered is in reference to draining it effectually, and this done the whole should be deeply trenched; or, should this be thought too expensive, the proposed distances at which the trees should stand apart should be marked out, and a space trenched for each tree, which space ought not to be less than 8 ft. in diameter.

Kitchen Garden.

Trenching and digging will doubtless have fallen into arrear, and if so these operations should be advanced as soon as favourable weather arrives. Advantage should be taken of hard frost to get all wheeling and carting completed, and also to get manure and vegetable refuse heaps turned over. Leaf carting and clearing up should also receive attention, and hotbeds should be made up preparatory to advancing sundry crops, such as Carrots, Radishes, Potatoes, Peas,

and French Beans. Early Broccoli not protected during the late severe weather will, doubtless, be found to be greatly injured, but late kinds have all escaped; still, it will be advisable in the event of another such a period setting in to protect them with bracken or long litter, and the same remark applies to Celery, Globe Artichokes, where not covered with protecting material at their base, will certainly be killed; some that were not covered have all but disappeared, but those mulched with long stable litter are safe. It will, however, be well to prepare for losses by making a sowing at once, and as soon as they are well up pot and grow them on in gentle heat, finally planting them out at the end of May. Plants so treated will yield a few fine heads in autumn. Having had complaints as to the toughness of Beetroot this season, it was all left in the ground and taken up as required, and the difference to the palate is certainly remarkable, and will lead to our always leaving it in the ground in future during winter, and covering it with bracken. Where there are not frames for the purpose Endive, Lettuces, and Parsley will also require a little protection, and nothing is more handy, neat, or effective than a few straw hurdles or roofing felt tacked to a light framework of wood made of convenient size for moving from place to place. These, supported by inverted flower pots or bricks, not only keep off snow, but many degrees of frost. On the first favourable opportunity a sowing of early Peas should be made; Ringleader and William I. are the two best varieties for this sowing. A southern aspect, sheltered from north and east winds, should, if possible, be selected for them. As soon as they are through the ground they will require protection against the depredations of sparrows, for once the latter get a taste of them, they clear a large quarter of them in a day or two. The best protections are wire guards, but where these cannot be had, stake the rows thickly with short, spray sticks, which will serve to protect them both from sparrows and cutting winds. A small planting of Early Long-pod Beans should also now be made on a warm border, for we find that the earlier these can be had the more they are prized, while, on the contrary, after other vegetables become plentiful they are but little appreciated. Decaying vegetable matter should in all cases, after a thaw, be forthwith cleared away to the manure heap, when, if thrown together and sprinkled with quicklime, it soon becomes a valuable fertiliser, and perfectly inodorous. In order to make some amends for the comparative barrenness of the garden at this season, let all walks and paths be kept in good order, and endeavour to maintain neatness everywhere.—W. W.

Public Parks and Open Spaces.

A few words as to what should be done in these during January may not be out of place. If the frost be not too severe, the digging of borders and plantations should be finished without delay, and in so doing, care must be taken that the roots of trees and shrubs are not injured; for such work no implement is better than a four-tined steel fork. Many object to disturb the soil after trees and shrubs have become well established, but, from long experience, I have come to the conclusion that this is necessary work in poplars, tunders, where the surface becomes coated with deleterious matters, rendering it impervious to air. In carrying out this work, all dead and useless wood should be removed, and where trees and shrubs are too much crowded, it is necessary to thin out and transplant, or take them out altogether. Great care must be exercised in this matter, as the appearance of plantations and shrubberies much depends upon the manner in which it is done. It will also afford a good opportunity for planting trees and shrubs which may be required for filling up blanks. All young trees should be firmly re-staked, and where herbaceous plants occupy borders round plantations, dead and decaying shoots and leaves must be removed, and the protection be given necessary to preserve the roots and crowns from frost. This may be tan, Cocoa-nut fibre, ashes, or similar materials. Trees and shrubs, the requiring it may be mulched with advantage. This is, likewise, season for forming new plantations, should the weather permit. Lawns or Grass plots do not require much attention, except where they are in very bad condition, and where they require levelling, re-turfing, draining, &c., of course much of this work depends upon the severity, or otherwise, of the weather; if favourable, however, no better time can be chosen for the purpose than the month of January. Lawns improperly drained are never satisfactory. Drain pipes should be placed in rows at from 15 ft. to 60 ft. apart, and at a depth of from 2 ft. to 6 ft., according to the nature of the subsoil, and with sufficient fall to ensure the water being carried off with rapidity. 6 in. or 1 ft. of brick rubbish, faggot wood, or, in fact, any kind of porous rubble, may, with advantage, be placed upon the pipes before filling in the trench, and should any subsidence occur hereafter, it must be rectified in the ordinary way, by lifting the turf and adding soil. Where breeze or ashes are easily obtainable, 1 ft. in thickness placed upon the ground, about

6 in. or 1 ft. beneath the level of the turf, will greatly improve its texture, appearance, and elasticity. Burnt ballast (burnt clay) will answer the same purpose, and is easily and cheaply made where clay is abundant. If the weather permits, Grass plots may also be cleaned by cutting out rough Grasses, uprooting Dandelions, Daisies, and other weeds. This, if done carefully, will cause no injury to the turf. Surface-dressing, which may consist of well-rotted manure, road drift, or artificial materials, should be spread upon Grass which is in bad condition in consequence of the poorness of the soil, or other causes, and will much improve it. Roads and walks, where made of gravel, must be kept in good condition by frequent rolling, and all channels, gullies, and drains should be thoroughly cleared out, in order that no water may accumulate which would render them unfit for ordinary wear and tear. January is one of the best months for re-metalling roads, or forming new ones, on account of the moist state of the materials, a condition which assists in binding them together. The best kind of stone for the purpose is either broken granite or flints. In re-metalling roads the surface should be broken up 2 in. or 3 in. deep, and from 3 in. to 6 in. of stone should be spread evenly over the whole surface; when this has been well rolled, 2 in. to 3 in. of fine gravel should be put upon the stone, and thoroughly watered and rolled. In forming new roads, after sufficient soil has been excavated to allow of from 15 in. to 18 in. of materials, and the drains laid, from 9 in. to 1 ft. of chalk, or brick rubbish, should be laid down, levelled, and rolled; then proceed as before to form the surface. Roads made according to these instructions will prove most durable carriage ways.—C. DENNIS, *Southwork Park*.

Woodland Work for January.

Those who have hitherto been in the habit of delaying all planting up of their woodlands until the winter is far advanced will have learned a salutary lesson from the enforced suspension of their operations, which took place early in December. We have for years persistently advocated the late summer or early autumn removal of evergreens, and the completion of the transplanting of deciduous trees by the end of November, and the rapid advance which such early removed trees make in the spring, in consequence of the roots having become turgid with the accumulated moisture, and the root-lets having made a considerable start before winter set in, ought to convince the most sceptical of the advantages of the system. The unusually severe weather which has set in while the land was saturated must tell severely upon young trees which had been just removed from warm nursery quarters. Though January is not a desirable month for continuing the work, on account of the frequent sudden changes of the weather, yet where a large breadth of woodland has to be filled up, the forester must avail himself of every open period for planting; he should now select the drier portions, reserving the wetter parts for operating upon in February and March.

Excellent opportunities have already been afforded for the removal of felled timber, which should now be, to a great extent, cleared off. Thinning should still be continued, but, at the same time, it should be remembered that neglected or overcrowded plantations may become permanently injured by too great a clearance or too sudden an exposure at this season of the year. The operation of thinning, like that of pruning, should be gradual, and both require the exercise of much sound judgment. Whoever undertakes the task while ignorant of the fundamental principles of vegetable physiology, must work in a twilight of uncertainty; and though sound common sense may prevent his doing any great amount of mischief, he will fail to accomplish the amount of good he might do if familiar with the principles of his operations. In executing thinnings of plantations, the principal consideration should be the permanent good of the standing timber, as, compared with this, the market value of what is cut down is unimportant. Thinning must be regulated by the closeness of the original planting as well as by the age and size of the trees, the quality of the soil, the amount of shelter or exposure, and the ultimate object of the plantations. Whoever plants thickly must thin early and frequently, or else fail to obtain the maximum amount of profit from his woodlands.

It is impossible to specify any limit for the distance of standards which shall be applicable to all trees; much must depend upon soil and climate. Where the production of timber alone is the principal consideration, the preservation of an unbroken leaf canopy will insure the tallest trees and the cleanest timber; but where it is deemed desirable to cultivate a considerable proportion of strong and healthy underwood, the standard trees should not occupy more than from one-third to one-half of the entire wooded area. Even in close plantations trees should never be allowed to overhang or whip each other. Firs and Pines may stand much thicker than deciduous trees, and during the earlier years of their growth they require much

less thinning; indeed, it is seldom necessary to thin a plantation of Scotch Pine until it is nine or ten years old. In situations where the deciduous trees require to be thinned out at intervals of from 25 ft. to 30 ft. at the age of forty years, resinous kinds may stand at little more than half that distance—say, from 15 ft. to 18 ft. In order to obtain sound timber no branches should be allowed to die back close to the bole. The process of natural pruning, by which the upper branches gradually destroy the lower ones by excluding sunlight and air may conduce to the production of the greatest amount of rough timber and fuel; but the largest yield of lengthy, clean, straight-grown, sound, and valuable timber is obtained by timely and continued attention on the part of the forester. Great care is necessary in the thinning and pruning of bells or narrow strips of plantation. If allowed to remain too thick the slender, drawn-up stems fail to produce the screen or shelter which was the object of the planter. Here an admixture of underwood will prove serviceable, and sometimes it may be found necessary even to pollard a few trees upon the margins in order to obtain the required density.

Continue to collect cones of the Larch, Scotch Pine, and Spruce Fir; those of the Larch in particular require to be well dried before being laid up in heaps. Towards the end of the month plant the remaining Acorns and Chestnuts, and in dry weather undercut the tap roots of two years' seedling Walnut, Oak, Chestnut, and Beech which are not to be transplanted; after cutting tread the soil well in around the plants. The seeds of Yew, Holly, Hawthorn, and Mountain Ash may also be taken from the pits and sown in open ground if the weather will admit. Wherever it may still be thought desirable to plant out single trees, either in the park or in the hedgerows, select strong and well-furnished plants which have become fitted for these positions by standing in fairly open nursery beds.

Hawthorns may be planted out for hedges, and old hedges cut off and plashed. Collect leaves from ditches, scorings of watercourses, and refuse soil of all kinds for making composts. Where trees have been cut off by the saw the work of grubbing and cording up the wood may now go on; though to-morrow is now coming into use for such operations, the work of the mattock and the beetle and wedges is not yet at an end. The cutting up or cleaving of a tree butt may, to the uninitiated, appear a simple operation, but we often see an athletic man wasting his strength while a less powerful but more expert man does the work with ease; the line of natural cleavage is from the heart or pith of the tree to the centre of each large root or spur, and, by inserting the wedges along this line, the stoutest butt is soon split up into segments, and these, in their turn, may be further reduced by taking off slivers in the direction of the annual rings.—A. J. BURROWS.

Fruit Trees in Kitchen Gardens.—It is well known that the art of maintaining a plentiful and regular supply of vegetables is one of the most important parts of practical horticulture. In the generality of private establishments, slight deficiencies in the fruit or flower department may be passed over, but the supply of vegetables must be kept up. Even in good soils, and with plenty of space at command, vegetable culture is by no means easy work, a great deal of judgment being frequently required to contend successfully with the variable and trying seasons so often experienced. Such being the case, and the importance of this branch of gardening being fully recognised, it is a matter of surprise that the owners of gardens should so often fail to afford sufficient facilities for carrying out the work with satisfaction to themselves, and credit to the person in charge. One of the most common complaints that one hears is, that the space devoted to vegetables is too limited, and a considerable amount of ingenuity has to be exercised to supply the wants of the household. Not only is this the case, but the kitchen garden is often so crowded with fruit trees, that a great portion of it is rendered almost useless for vegetable culture. Whilst the trees are young they are not much in the way, but year by year they encroach upon and shade the ground, and it is found almost impossible to keep up either the quantity or quality of the vegetable crops. When there is plenty of land, I only consider planting fruit trees in a walled-in garden a mistake; it not only cripples the vegetable supply, but the fruit crop is apt to be deficient. Many instances have come under my notice, where the standard Apple and other fruit trees were crowded into the vegetable ground, when there was an abundance of good soil in the immediate vicinity occupied by ordinary farm crops or coppice wood, where fruit would have flourished better in every way.—J. CORNHILL, *Blyth*.

Crocus speciosus.—This has continued to flower freely at Tooting all through the severe weather, and a good display of it will shortly be found where the soil is light and well drained.—S.

NEW OR RARE PLANTS.

A MINIATURE TREE FERN.

(ATHYRIUM SCANDICINUM).

THIS beautiful little Tree Fern is a native of the Sandwich Islands, and was introduced from California into this country by Mr. Williams, junior, and it has been exhibited by Mr. B. S. Williams under the provisional name of *Alsophila plumosa*. By some botanists it is associated with *A. aspidioides*, a variable species having a wide range in Tropical America, South Africa, and India. Perhaps this is a correct view, for the different specimens we have seen of *A. scandicinum*, from the Sandwich Islands, differ more from each other than they do from some of the specimens of *A. aspidioides* from other regions. Be that as it may, there are several varieties sufficiently distinct from each other to deserve cultivation. Like the Lady Fern, to which the present species is closely allied, *A. scandicinum* varies very much in the degree of fineness of the cutting of the frond, and in the relative development of the stem. The variety before us is a Lady Fern, with finely-cut fronds and a short, stout trunk; indeed, we might justly call it the Tree Lady Fern. Its small size, as a Tree Fern, combined with the grace and elegance of its foliage, renders this one of the most attractive of recent acquisitions in a family so rich in beautiful forms, and in which there is so much variety.

W. B. HEMSLEY.

BAPTISIA (False Indigo).—Tall and stout herbaceous perennials, with ornamental leaves and fine long spikes of handsome, blue, Lupin-like flowers. Being among the most hardy and vigorous perennials, they will thrive well in almost any position in woods and copses, and well-grown tufts of them would look to great advantage near wood walks. They grow well in almost any soil. The species are North American—the best cultivated kinds being *B. australis* and *B. tinctoria*, which inhabit dry and alluvial soils (as distinguished from boggy places) in the United States. In England they thrive on moist or clayey soils as well as on those of a more open nature.—V.

THE KITCHEN GARDEN.

FORCING SEAKALE AND RHUBARB.

By the present system of forcing these two esculents, all uncertainty as regards production is done away with; and now we almost know to a day when we can cut, whatever the state of the weather may be. So accommodating, indeed, are Seakale and Rhubarb as to admit of being dug up bodily and forced in any hole or corner where there is waste heat; but the best place of all is a Mushroom house, and any one who has a structure of this kind may have them in prime order and with great regularity the whole winter through. In the genial, sweet

atmosphere that there prevails, they always come free from taint, and are invariably tender, rich, and succulent. The only time when there is any deviation from this is when more is put in at one time than there is use for, and it, in consequence, remains long uncut, when it becomes stringy and tough, which no amount of boiling or good management in the kitchen will rectify. This, of course, only applies to Seakale, as age and length of stalk little affects Rhubarb, except in a favourable way, by rendering it more solid and less watery, and, therefore, of superior quality altogether than could otherwise be expected. In places where there is not the convenience of a Mushroom house, and there is any back wall warmed by a

A Miniature Tree Fern.

boiler chimney or flue, a good way is to enclose a space with bricks, and line them up round with soil, so as to form a sort of pit, over which a shutter can be fitted, and then cover the roots over with straw to exclude light and prevent the heat from escaping. Thus circumstanced, both these esculents grow beautifully, and require no attention beyond an occasional watering to keep the earth about the roots moist, as any vapour that escapes surcharges the internal air and maintains it in a healthy condition. If the pit is large enough to admit of a few fresh roots being put in every fortnight or so till others can be got out and replaced, a constant succession may be kept up till they can be had from the open ground.

Another capital plan of forcing Seakale is to get a very large flower-pot, and pack into it as many roots as it will hold,

with a fair quantity of light rich soil between them, and then plunge it in a bed of leaves, or other gently-fermenting material, with another pot of the same dimensions turned over it, when, if this is again covered with litter, some splendid heads may soon be had. In digging the roots of Seakale up, those with the largest and best-developed crowns should be chosen, and the same with Rhubarb, for, unless the plants have been well grown, what they yield must of necessity be meagre and poor, as all depends on their strength at the time of starting, and the amount of organisable matter they have stored up in their stems. One great advantage in forcing these vegetables in this way is that, unlike Asparagus, the plants of which are spoiled for ever after, and have to be discarded, Seakale and Rhubarb are none the worse after a season's rest and fresh growth, as they may then be taken up and used for the same purpose again. Instead, however, of planting the old, thick portions of the stems of the Kale, I prefer the large and tough roots, numerous pieces of which break off at the time of digging them up, or may be saved after the forcing is over. These cut into lengths of 4 in. or 5 in., or so form excellent sets and start away vigorously in spring as soon as warm weather sets in. When preparing these for planting, I always make a practice of cutting the lower end sloping and the top flat, otherwise, so near are they alike as regards size that it is impossible to distinguish between the two, and they would most likely, therefore, be planted the wrong way upwards. These sets or cuttings may be made and dibbled out in rows at any time, but it is quite as well to bury the whole in moist sand or ashes as they come to hand till the whole is ready, and then put them out. This should be done in ground that has been trenched and thoroughly enriched with well-rotted manure, as Seakale is naturally a gross-feeding plant, and likes to penetrate deeply in search of moisture.

Salt, added to the manure or sown over the ground in May or June, is a capital help, as it not only acts as a suitable stimulant, but destroys seed weeds, and thus saves time and labour in hoeing. The proper distance for the rows is about 15 in. apart, and 1 ft. from plant to plant, which affords sufficient room for a full spread of the leaves and admits of their full development, which would not be the case were they nearer together. For permanent beds, where the heads are covered with pots or are blanched in any other way, the rows should be at least 2 ft. apart, and the plants placed triangularly about 9 in. from each other down the rows, so that each clump of three has a space of 18 in. between. I find a very good way of getting fine late Seakale is to cover the whole bed during winter, with long stable litter, under which the heads come on slowly and beautifully white, as well as being very tender and succulent. Besides being propagated and increased by means of cuttings of roots made in the above-named manner, Seakale grows readily from seed; but plants so raised, unless under exceptionally favourable circumstances, take two years before they are large enough for forcing, whereas the others are quite strong enough in half that time. To get large crowns of Rhubarb, it is a good plan to dig large holes and work a quantity of manure in the bottom before planting, adding more when filling in the soil around the sides, and if, in addition to this, sewage be given occasionally during the summer, growth will be most rapid and vigorous. What is required for forcing should not have any pulled from it, unless it be a few sticks early in the season, as the loss of every leaf decreases the plant's strength and capabilities for the following season. S. D.

February, and the result was no difference between the two sowings. A neighbour, who sowed in December and again in February, had only an advance of a day in favour of his plan. Last season I sowed here (North Hampshire) Dickson's First and Best and Laxton's Alpha in the open border, and also some in strips of turf for planting out on January 18 and again early in February in the open border. Those sown on turf were put into a Vinery and then hardened off in a cold pit, and from these I gathered May 28. Those sown in January and February in open borders yielded usable pods on June 3, there being no difference between the two sowings. When in Dorset and Norfolk my experience was much the same. The earliest time I ever remember to have seen Peas gathered from that were sown in the open ground was on May 17 or 18, and this was at Haywood House, Westbury, Wiltshire, some few years ago; however, this is undoubtedly not so early as they are in warmer localities. My experience is unfavourable to Kentish Invicta; I have grown it two or three times, but I did not find it a sort to which I could trust. It rotted in the ground when sown before the middle of February, and it is not so good a cropper as many other sorts. No Pea have I ever had as an early one to beat Dickson's First and Best.—J. C. F.

SITES FOR KITCHEN AND FRUIT GARDENS.

As a well-designed whole is always better and more satisfactory than fragmentary work can ever be, so, in selecting the site for a gentleman's residence, not only the mansion itself, but also the whole of the appurtenances belonging thereto, should be taken into consideration, and duly marked out on the plan, with special reference not only to the relations they bear to each other, but also that each may occupy the most favourable position for securing the objects for which it was intended. Now, the kitchen and fruit gardens certainly form no inconsiderable part of what may be termed the necessary adjuncts of a first-class establishment; and there are several matters in connection therewith that come more especially within the province of the practical gardener, and which I know to be often overlooked by the architect or landscape gardener. These are mainly shelter, soil, aspect, and elevation. It is no uncommon occurrence to find extensively-constructed gardens dropped into some hollow, as if the main object had been to get them out of sight; or, it may be, the extra depth of alluvial soil in the bottom of the valley had proved an irresistible temptation. No doubt depth of soil is an important matter, and forms one of the constant aims of the practical cultivator; but the bottom lands in the valleys are well known to be several degrees colder than the sloping hillsides. The cold fogs are carried down by their own weight and the moving force of currents of air till they reach the lowest points, where they chill and freeze everything at all tender. This is more especially noticeable in spring and autumn, as every competent observer may easily ascertain for himself. In such positions it is next to impossible to obtain good crops of fruit or early vegetables, for the hoar frost destroys the tender blossoms of the one, and checks and blackens all tender growths of the others. The difference of a few feet in the elevation of a garden or orchard has a wonderful influence in this respect. The crops of fruit and early vegetables in one garden may be ruined by spring frost, whilst another in the same neighbourhood, but situated at a slightly higher level, may escape altogether; and this fact alone will account for much of the variation that is constantly occurring in English fruit gardens. In low-lying gardens, too, there is often a difficulty in securing an outfall for the drainage; and even if the land be naturally dry, there are stake-holes, fruit borders, walks, and other points that must be laid dry, and for which a good drainage outfall is necessary, or they will be an endless source of trouble. The best site for kitchen and fruit gardens is on the site of a gentle slope, where the inclination does not exceed 1 in 20, and preferably less. A southern aspect is best, but a point or two either east or west will not matter. It may be an advantage to have the shelter of hills to east and west as well as north, but such favourable positions are not often met with, and it is of but little importance, as, unless the culinary gardens are placed at a considerable distance from the mansion, it will be necessary to plant screens and shelters of trees and shrubs to blind them. Though a well-managed kitchen garden is at all times an interesting study, yet there are objections to its being placed in too conspicuous a situation, at least so far as regards its worst features; such, for instance, as the backs of sheds or offices being visible from any window or any part of the grounds. But this is a detail than can be easily arranged without creating an eyesore. The shelter belts or screens should not be placed too near, if anything beside shrubs are used, as, in the winter especially, they may give too much shade and prevent the land drying properly.

The most important matters next to aspect are elevation and soil, as shelter can easily be secured by raising plantations, and these are

Winter-sown Peas.—My experience of Pea sowing does not agree with that of Mr. Legge (p. 530), although I must say, at the outset, that seasons, and soils, and situations have a great deal to do with late-sown Peas; but I believe that in nine cases out of ten (and the same as regards seasons) Peas sown some time in January, all points considered, are to be preferred to those sown in the autumn. When I was in Backinghamshire we used to sow in the end of October or beginning of November, on a south border, and again in January, but when the picking time arrived only two or three days were gained by autumn sowing, and the crop was not so heavy as that on the January sowing. Some of the rows were very much injured by slugs and other causes to which autumn-sown Peas are so liable. In 1874 I was in Dorsetshire, on the seacoast, twenty miles from Weymouth. There I sowed January 15 and again early in

generally necessary for other reasons. In large establishments the kitchen gardens are often placed a considerable distance from the mansion and private grounds, but this adds a good deal to the expense of keeping. There is a great loss of time in moving plants, manures, &c., from one department to the other, and I cannot see, if the departments are so separated, that there is any corresponding advantage; there should be no difficulty in hiding any feature that may be objectionable, and the kitchen gardens may be—indeed, ought to be—a pleasant sheltered promenade at all seasons of the year. To a mind capable of being roused to a study of such matters, there are many interesting features in the cropping and management of a kitchen garden; and as regards fruit growing, either under glass or in the open air, there is always something to attract attention. In the winter there is the pruning and training to be seen to; and when the trees are bare, the different styles of growth of the various kinds of fruit trees are brought out more prominently, revealing the fact that, like human beings, it is difficult to find two in all respects alike. And as the days lengthen, and the buds begin to swell and unfold in succession, how absorbing the interest becomes; and it continues to increase, and only culminates when the treasures are gathered in and stored away, in autumn. I am sorry for those people who are anxious to hide up and place out of sight altogether the culinary department, because they lose a most interesting subject for study. There has been a tendency during the last quarter of a century to place fruit and vegetable growing in the background. I think scarcely anyone who knows what gardening was at the period to which I have referred, and has watched its growth since, will deny that such growth has been mainly in ornamental gardening and in the glass erections which the style adopted has rendered necessary. There is scarcely one place in ten at the present time where the kitchen gardens are not starved, both in labour and manure, in order to keep up the expensive show in the ornamental department. This would not continue if employers took a greater interest in fruit and vegetable growing; and no doubt by-and-by things will right themselves again.

Assuming that the residence with its buildings occupies the crest of an eminence, the kitchen and fruit gardens might be appropriately placed on the flanks, sheltered and surrounded where necessary by belts and groups of trees and shrubs, and among whose sheltering folds might be found excellent positions for groups and plantations of choice fruit trees. Arranged in this way, the whole south front would be open to be treated in any manner most in accordance with the character of the building, or most agreeable to the wishes of the owner. The size of the kitchen garden must depend in some measure upon the demand that is likely to be made upon it; but very large gardens in these days of dear labour are, I think, a mistake, at least so far as regards the walled inclosures. No doubt an extensive system of walled inclosures gives a large extent of surface for training wall trees, as well as a variety of climates in their different aspects, that are not without their uses. But I think the time will come when fruit-growing, as regards the choicer kinds at least, will be carried on more under glass, and then fewer walls will be required; and, as all the coarser kinds of vegetables can be better and more cheaply grown outside the garden walls, the walled-in space may be much curtailed, and reserved for early vegetables, salads, and such like. The sides of the paths may be utilised, as at present, for Pears and Apples or other fruits on espaliers; but fruits and vegetables do not agree well together on the same plot.

I have seen in Worcestershire and elsewhere good crops of Apples grown in the Cornfields, where the plough is used almost close to the trunks of the trees; but the rows of Apple trees are at wide intervals apart, and the plough does not stir up the soil so deeply as the spade. Surface culture under large spreading trees, I believe, is beneficial; but then such trees have obtained a firm grasp of the soil, and, what is more, the soil for several feet in depth is not inimical to their well-doing. But on land under spade culture, if fruits and vegetables are mixed, it is generally at the expense of both. The plan that appears to me to offer the best chance of coping successfully with the altered state of things which we must expect in the future, is to build a few roomy span-roofed houses, to make sure of a crop of the choicer kinds of fruits; to have a much smaller walled-in space, and to devote that mainly to trained fruit trees, early vegetables, and salads; whilst the bulk of all vegetables crops should be grown entirely outside the garden walls. It is not easy to form an estimate as to the space required to grow fruit and vegetables for a given number of persons, as the requirements of different establishments vary considerably; but to supply well, all the year round, an establishment of (including servants) twenty-four to thirty persons, allowing at the same time for visitors and the customary parties being given, will require about five acres of good land. Supposing the family have two country residences (which is a common occurrence), then about three acres at each would suffice. The best form for the walled garden is for the north of the kingdom an oblong parallelogram, with the

longest faces pointing to the south and north, for the purpose of securing a greater extent of south wall. In the south a square garden will be more suitable, as good fruit can be grown on eastern or western aspects, and an unusual length of south wall is less sought for or required. One of the most important matters in connection with vegetable and fruit growing, if all things are to be well done, is a good supply of pond or soft water. For some reason hard to discover, this want has not had so much attention given to it as its importance deserves; and when the site for the gardens is chosen it should be borne in mind, as any arrangements it may be necessary to make, to secure a good supply of this indispensable fluid, will be more economically carried out then than afterwards.—“Field.”

AFTER THE FROST.

THOSE who, like myself, are growers of hardy plants, both in pots and in the open ground, will have cause to look after their plants now that thaw has followed severe frost. In my cold house, and also in my outdoor frame, the possibility of frost coming at Christmas or thereabouts had been considered. All hardy Primulas in pots, Auriculas, Polyanthus, Primroses, and the representatives of various species, also Christmas Roses, Pinks, &c., had been allowed to become pretty dry, and when the frost came there was but little moisture in the soil for it to fasten upon. The great danger of frost laying hold of the soil in pots, consists in this, that when it is pretty moist, the expansion caused by frost will crack the pots, hence the importance of the soil being as dry as possible when it threatens. My cold house has a north aspect, and there was an additional reason for avoiding a superabundance of moisture. The first night of the sharp frost everything was frozen, and newspapers were carefully laid over the plants two or three thick, but the plants, the papers, the glass, and rafters, were all encased with hoar frost. The papers were left on the pots till the thaw had passed through the house, to keep the drip from the melting hoar frost from falling on the plants. Quite small plants of some delicate-growing Auriculas are unharmed. The only sufferers have been the greenery here and there; all the life has gone out of them. I have gone over the plants, picking off the decayed foliage, pressing down the soil about the roots, and giving a little water where necessary, but taking care to thoroughly soak the soil of plants that are quite dry. It is surprising how fresh and well they look after being gone over and touched up in this way. The fear is that if this mild, close, moist weather continues, some of the Primulaceae, and especially the Auriculas, will become preternaturally active. The time for moving will soon be here, but I shall be in no haste to witness it. It is an old saying that “the ice that will bear a goose before Christmas will not bear a duck afterwards;” but there may be an abundance of skating yet, and premature activity in plants brings no gladness to the heart of the florist.

On a raised ash bed in front of my cold house are Polyanthus, Aquilegias, Anemones, and many species of Primulas, &c., in pots, and it was a matter of considerable anxiety that the frost would do harm here. As soon as there were indications of its being severe, light strips of wood reaching higher than the points of the foliage, were laid on the rims of the pots and over these a covering of old newspapers, and upon these garden mats and old pieces of sacking. Then came the snow and added to the covering, and though the frost penetrated through to the soil of the plants, it was felt the covering had averted its effects. This covering was kept on for more than a week, and when the time came to uncover, not a single pot was broken. It was necessary in many cases to litter the soil about the plants, and the soft rain which fell subsequently, has decidedly refreshed them. Not a single loss has occurred so far as can be ascertained at present. Beds of Auriculas, Polyanthus, and other plants in the open ground, not having the advantage of covering have had the soil much loosened, but a gentle pressure soon restores the plants to their proper positions. About the middle of December the beds were well top-dressed with a mixture of leaves and ashes from a burnt heap of refuse. The leaves lying roughly on the surface formed guards from the cold, and the plants appeared to nestle among them as if feeling quite secure. There is nothing like a good top-dressing of this kind in autumn. It is an excellent protection during winter, and in spring it mingles with the surface soil and affords nutriment for the plants. I never waste any house refuse of a vegetable character, and indeed everything that will rot or burn is utilised for the garden. It is laid by in a heap, and when required charred till it is fit to be used as a top dressing. Times of severe frost are not without their uses to gardeners, though they have their attendant discomforts. A small heap of manure infested with worms and other insects was turned over two or three times during its continuance, and the birds and frost combined, have cleared it of insect life.

GARDEN DESTROYERS.

THE COMMON DARK MOTH OR TURNIP MOTH.

(AGROTIS SEGETUM.)

This moth is very common, and is very generally distributed throughout the United Kingdom, and, in fact, over a large portion of the world, as it may be found in almost every part of the Continent, and is very abundant at the Cape of Good Hope. The caterpillars of this insect, as well as those of several nearly allied species, are generally known by gardeners and farmers by the name of "the grub." This species is particularly troublesome both in the kitchen and flower gardens, as well as to certain farm crops, by feeding on the roots and leaves of various plants. Among its favourites are Auriculas, China Asters, Dahlias, Balsams, &c., and in the kitchen garden Cauliflowers and Cabbages of all kinds, Lettuces, Spinach, Beetroot, Radishes, Turnips, &c. On farmland at times it does an immense amount of mischief to crops of grain of all kinds, Mangold Wurzel, Swedes, and Turnips. These caterpillars generally begin by attacking a plant at the crown or a little below it, and do most damage among young plants, whose roots they eat right through. In some seasons they appear to continue at their work of destruction all the year round, in the winter feeding on the lower parts of the roots. There does not appear to be any way of destroying the eggs, which are laid by the moth in the earth near the roots of plants; but many are, no doubt, destroyed by various birds and beetles. As the caterpillars only feed at night, remaining under shelter during the day, it is not very easy to destroy them. Salt and water, in the proportion of 1 oz. of salt to a gallon of water, has been found very efficacious, when

Agrotis (Noctua) segetum.

the plants have been well watered with this mixture, in preventing the caterpillars from attacking them. Soot laid thickly on the ground, dug in or placed round the roots, and then covered with earth, has been found to be very useful in keeping them away. One pound of soap mixed with sixteen gallons of water, applied warm to the roots until the neighbouring holes and cracks in the ground are full, will cause the caterpillars to come quickly to the surface, when they can easily be collected. Tobacco water would kill them if it could be applied so as to reach them. If in great numbers, search should be made under clods and stones, not only near the plants which are suffering, but round those which are not yet touched, for the caterpillars, and the plants may be searched after dark with a lantern. Their natural enemies are numerous; moles, several kinds of beetles, and various birds help to keep this pest in check. The rooks, perhaps, are their greatest foes, and, though they are often accused of doing much damage in gardens and fields to various crops, it will seldom or never be found that they destroy a plant which has not already been attacked by some insect; on no account should these useful birds be scared from gardens. The moths are very difficult to find during the daytime, on account of their dull colour and their habit of remaining in some sheltered place until dark, when they may be found during the summer months flying about at times in great numbers, the males being generally much more numerous than the females. The chrysalis may often be found when garden ground is being dug, and should always be destroyed. The moths make their appearance in June, and may be found during the summer, and as late as October. The females lay their eggs in July or August, choosing a position in some light earth near the plants which will afford food to the caterpillars, which are hatched in ten or fifteen days, and they remain hidden during the day under clods and stones, or in

holes which they form for themselves, 2 in. or 3 in. deep in the earth; at night they emerge from their shelter, and carry on their work of destruction until dawn, when they again hide themselves. They can move at a surprisingly rapid rate, and as soon as the root of one plant is eaten through they are off to another. Ten or twelve have been found at the root of one Turnip, and in France very great damage has frequently been done to crops of Beetroot. A few of the caterpillars become chrysalides in October, from which the moths appear in a few days; but they mostly burrow 2 in. or 3 in. into the earth at the approach of winter, and live on the lower part of the roots of various plants, or, forming an egg-shaped ball of earth round themselves in which they are sheltered from cold and damp, pass the winter in a torpid condition. Early in spring they reappear, and in May or June again descend into the ground and form a rough cell, in which they change into chrysalides, from which the perfect insects emerge in about a month. The moths measure about 1½ in. to 2 in. across their expanded wings. The males may be distinguished from the females by their lighter colour, the greater distinctness of their markings, and by their antennæ, which are very finely toothed, whilst those

Caterpillars of Agrotis segetum.

of the female are smooth. The upper wings of the male vary in colour from pale greyish-brown to yellowish and reddish-brown. Those of the female are dark chocolate or reddish-brown, with the markings very much blended with the general colour. In both sexes there are two double wavy, transverse, blackish lines on the upper wings, between which, near the upper margin, are two spots, the nearest the base being surrounded by a lighter ring, and the other being somewhat ear-shaped and blackish. Near the outer margin is a very irregular dark double line. The lower wings of the male are pearly white; those of the female dirty white, with the margin darker. The thorax is of the same colour as the upper wings; the body is greyish-brown, somewhat lighter towards the base. The caterpillars, when fully grown, are 1½ in. to 2 in. in length, and have eight pairs of legs, the first three joints of the body being each furnished with a pair, as well as the sixth, seventh, eighth, ninth, and last joints. The head and first joint of the body are horny, very smooth and shining, and brownish in colour; the latter being marked with three paler lines. The eleven other joints are smooth, shining, and of a smoky yellow colour, the back being somewhat pinkish or purplish. There are three longitudinal pale stripes, bordered with a dark line on either

side, one down the centre of the back, and one on each side, of the caterpillar. On each joint are ten slightly-raised, darker spots, each bearing a hair; four are placed on the back, two in front (one on either side of the central lines), and two behind in the same position; the others are placed three on each side, just above the feet, in the form of a triangle. The chrysalides are about 1 in. long, and are of a bright brown colour.

S. G. S.

THE GARDEN IN THE HOUSE.

CULTURE OF PLANTS IN WINDOWS.

THERE is no branch of gardening which embraces such a wide range as that relating to the culture and preservation in a healthy state of plants in dwelling houses. There are and always will be so many who have no frame or greenhouse, that the question of how to grow plants successfully in windows is necessarily of the greatest interest to them. Those who have even the convenience of a cold frame will, of course, find the task of decorating the dwelling much facilitated; but, as I have said, there is unhappily a great portion of our population who not only are not provided with this simple accommodation, but whose garden is of the most fragmentary character. This is more especially the case in large towns where windows in many parts form almost the whole available space in which garden operations are conducted. There is, however, no reason for any one to despair of attaining success, for I have noticed that it is more from a want of knowledge than from adverse circumstances that failures occur.

Choice of Subjects for Cultivation.

Formerly the choice of plants suitable for culture in rooms was somewhat restricted, Cactuses and various other kinds of succulents being mainly relied upon for that purpose. Now, thanks to the exertions of plant collectors and to the improvements which have been effected in many of our florists' flowers, we have an abundance of subjects from which to choose. It is almost impossible to give a list of plants suitable for every one, as the conditions of air, light, warmth, and atmospheric humidity vary according to the situation and uses to which the rooms are put. For instance, a plant that would do perfectly well in an apartment that is not constantly occupied, where ventilation is somewhat freely given, and where artificial heat is but seldom applied, will linger and die where a fire is constantly kept and oil or gas is freely burnt. On the other hand, we shall find certain plants that can only be kept in health by placing them where they are screened from draught, and where the air is maintained at a certain temperature. The care which these two classes of plants will require will necessarily be of an entirely different description, and it is just in this respect that the plant grower in windows will have to exercise judgment. As an illustration let us take the *Cyclamen*, a beautiful window plant, but one which will only succeed in a cool room; confinement is certain death to it. An india-rubber plant, on the contrary, will thrive best if kept tolerably close, but it must receive certain attentions which the *Cyclamen* will not need. It will thus be seen how widely varied the treatment of room plants must be, and how necessary it will be to choose suitable subjects for each situation. Then, again, we must take the aspect of each window into consideration. A Moss or a Fern will thrive admirably where a *Fuchsia* or a *Pelargonium* will give but little satisfaction. In most dwellings there are windows having different aspects; all that is necessary, therefore, is to ascertain in which of them the desired plant will best thrive. The various types of vegetation, flowering and fine foliated plants, &c., may be all represented, and the grower will thus be enabled to secure a series of plants, pictures, as it were, each one presenting distinct characteristics of its own. Whilst indicating a few of the plants best adapted for window gardening, I would advise that growers should allow some scope to their individual likings, and make trial of those plants which they may have a fancy for. There is much yet to be accomplished in this branch of gardening, and the pleasure and honour derived will be in proportion to the diffi-

culties surmounted. There are many plants now considered difficult of culture which probably only require to be better understood to render them amenable to room culture. For a confined atmosphere, such as an ordinary sitting-room, we must rely chiefly upon fine foliated plants, those possessing leaves of a somewhat hard, leathery nature being the easiest to preserve in health. *Ficus elastica* and *Chauvieri*, *Aspidistra lurida* and its variegated form, *Dracena terminalis*, *congesta*, and *indivisa*, *Cordylus rubra*, *Chamærops excelsa*, *Livistona borbonica*, *Corypha australis*, *Maiden-hair*, and other Ferns are amongst the best for such situations. For apartments that are but occasionally heated, *Grevillea robusta*, *Acacia lophantha*, *Aspidistras*, *Chamærops excelsa*, *Aralia trifoliata* and *reticulata*, *Cyclamens*, *Solanums*, *Primula sinensis* and *denticulata*, *Violets*, *Mignonette*, *Tropæolum tricolorum*, and bulbs of all kinds may be grown. The plants enumerated are all suitable for winter and early spring. In summer we get a much greater variety. *Pelargoniums*, *Fuchsias*, *Lobelias*, *Petunias*, and all the various kinds of bedding plants will grow and bloom admirably in windows during the summer season. A very effective and gratifying display can be made by sowing different kinds of annuals in boxes made to fit and affixed to the outside of the window. *Nasturtiums*, *Sweet Peas*, *Eschscholtzias*, *Mignonette*, *Phlox Drummondii*, and such free-growing, persistent blooming plants when thus grown make a dwelling very pleasant to the eye. This method of floral decoration is not nearly so much adopted as it should be; the cost of a box or two and the necessary fittings, as well as the small amount of seed required to sow them, is very trifling, the cultural care, too, being of the simplest. Windows facing the north and east are most suitable for boxes, inasmuch as they there get only the morning and afternoon sun, and, being shielded from the fierce noonday heat, the flowers last longer in perfection. For a northern aspect there is no more beautiful plant than the common *Moneywort*; when well grown it forms a drapery of lustrous green and bright yellow, such as is scarcely equalled by any other plant. In windows facing the north nothing will give more satisfaction than Ferns and Mosses, which, at all times lovely, acquire additional luxuriance and beauty in just those very places where most other plants refuse to flourish. Any of the following may be selected, they being all of fairly easy culture: *Asplenium bulbiferum*, *Adiantum Capillus Veneris*, and *conestum*, *Pteris cretica* and *scaberula*, *Oncidium japonicum*, *Davallia Novæ Zealandiæ*, *Niphotolus Lingua*, and *Selaginella denticulata*. Succulent plants should not be omitted, as they afford variety, give but little trouble, and are really interesting; they must, however, be grown where they get the full heat of the sun. Many of the old-fashioned plants, such as the *Candle plant* and the *partridge-breasted Aloe* are now but seldom seen. They are, however, very distinct in manner of growth, and deserve a little more attention than they now get. *Vallota purpurea* is a handsome, evergreen, bulbous-flowering plant which anyone may grow. *Campanula Barbellieri* is a pretty little trailing plant suitable for a small basket. I once saw a beautifully flowered specimen of it hanging on the outside of a window in a crowded part of London. *Saxifraga sarmentosa* and *Cactus fabelliformis* may be both employed in the same way; the one in a shady situation, the other in the full sun. The plants above enumerated may all be cultivated and kept in health in the dwelling-house. There are, of course, a great number which may be introduced for a time into apartments, but which cannot be retained therein without injury, but of these it is not my intention to treat. The owner of a glass house will, of course, not need to grow these plants in the windows of his residence.

General Treatment.

It will naturally be understood that cleanliness is of the first importance to plant life. Leaves breathe, as it were, through their pores, and if these be choked by impurities of any kind, the functions of the plant are in a manner paralysed. The more confined the atmosphere the greater need is there for frequently washing and syringing. All plain, hard-foliated kinds should be well sponged, using plenty of clean tepid water. Ferns, Mosses, &c., may be gently but thoroughly syringed, taking care that the under surface of the foliage is well cleaned. Insects often make their appearance, and must be kept under either by

brushing them off with a soft brush or by means of fumigation. The latter is the most effective method, although if the stitch-in-time principle be acted upon and the first insects destroyed, there will seldom be any need for it; should a plant, however, become badly infested, place it under a tub and fill the same with Tobacco smoke. Two applications at the interval of a few days will generally suffice to clear them all off. When we come to watering we touch the most difficult part of our subject. It is utterly impossible to lay down hard and fast rules; the attempt to do so would merely result in disastrous failure; nothing but practice can give proficiency in this branch of plant culture. The great point to be kept in view is, that in winter water is merely required to maintain life, whereas in summer when the functions are active and growth progressing, enough must be given not only to supply waste, but to allow of the extension and formation of new tissues. Were these facts kept constantly in mind, there would not be many disasters arise from over-watering. In dull, sunless weather let each plant dry out thoroughly, and then give just enough to well moisten the ball of earth. In a hot parching time this care is not so needful; if the roots are healthy, and the plant growing freely, copious and frequent waterings must be the rule. These general rules will form a basis upon which the grower may safely work. They will, however, have to be varied and modified according to circumstances and the plants cultivated, but for the acquirement of this knowledge he must rely upon constant practice and unremitting attention. In the matter of ventilation be careful to avoid cutting draughts; much harm is often done by injudicious air giving. Do not either run into the common error of turning your plants out upon the doosteps or balconies in weather which, although sunny, may yet be of a chilling nature. Harden gradually on the approach of spring by increasing the amount of air, and only turn them out-of-doors on mild, moist days. A safe rule is to be guided by one's own feelings; if the atmosphere be congenial to the human frame it will be beneficial to plant life, and *vice versa*. That, at least, is the conclusion at which I have arrived.

Potting and Propagating.

Many who grow window plants make a point of getting them shifted by a professional cultivator. This is, however, by no means necessary, and is wrong in principle, as the nature of a plant is but imperfectly understood if its root action cannot be observed. I would advise that the soil be purchased at a nurseryman's, stating for what kind of plant it is required. Be careful never to give large shifts, and see that your soil is well sanded and not too rich; any little deficiency in nutriment can easily be supplied by a top-dressing of any of the concentrated manures. For Ferns and delicate-rooted subjects allow plenty of drainage; in fact, all kinds of plants grown in rooms should be amply provided for in this respect. Nothing can be more injurious than a stoppage of the drainage, and to secure immunity from injury in this respect, each plant should be examined at the commencement of the winter, and fresh drainage given, if found necessary, using some good clean potsherds or broken charcoal for that purpose. There is no reason why window gardeners should not try their hands at propagating; it is amusing, and greater pleasure is derived from the culture of home-struck plants than from those which have to be bought. Most of the so-called soft-wooded plants may be increased with ease, and if a few cuttings be put in every year, they will supply the place of plants which get too large. The appliances necessary will consist merely of a few bell-glasses, some soil of a light description, and some silver sand. Fill the pots to within 2 in. of the rim with soil, and finish off with sand, making the pot quite full. The pot should be filled about one-third of its depth with drainage. The cuttings are inserted in the sand and kept covered with the bell-glass until rooted. Fuchsias, Heliotropes, Verbenas, Lobelias, &c., may all be struck in this manner in an ordinary living room. Pelargoniums only will need no covering. Put each cutting in a small pot; it will root freely enough. Seeds of annuals may also be raised by sowing in a pot filled to within 1 in. of the rim, and covered with a piece of glass until fairly up. I have here indicated comparatively little of what may be done in the way of window gardening, but

enough, I think, to enable even beginners to try the undertaking with a fair prospect of success. I trust that they may not be daunted by a few failures for, permit me to add, in this, as in every other branch of gardening, there is no royal road to success.

JOHN CORNHILL.

Byfleet.

THE FROST AND THE THAW.

It is, probably, rather early to write positively as yet of the effects of either of these, but, as far as appears, the effects of the frost seem less disastrous than might have been expected from its great length and extreme severity; and if vegetation has escaped with less injury than usual, this has arisen from the mode of thawing rather than from any lack of severity in the freezing. It was a rain thaw, and no doubt that is the very best. The water relaxes, as it were, the hold of the frost in vegetable tissues, and draws the ice out gradually and gently without rupturing them. It is somewhat singular that vegetable tissues, unlike water pipes or other mere mechanical tubes, seem to burst rather in the thawing than in the freezing. It is the suddenness of the former, rather than the severity of the latter, that seems to kill plants; hence, partly at least, the greater destructiveness of spring than of winter frosts. No doubt the sap is also more plentiful and more active in the spring, but it is probably the greater energy of the sun, and consequent rapidity of the thawing of vegetable tissues, that render spring frosts so exceedingly and exceptionally destructive. Be this as it may, it is pleasing to note that the severe frosts seem to have passed away without any very serious injury. Even the Laurustins, generally the first to be browned or killed here, seems to have escaped, and looks as if the full head of bloom even would still expand. This comparative immunity from injury as regards shrubs and plants could hardly, I should think, arise from the amount of snow that has scarcely sufficed to cover them. Possibly, however, the unusual amount of hoar frost might have helped to keep the plants warm. I never remember seeing so much hoar frost for so long a time as this winter.

D. T. FISH.

Hardwick House, Bury St. Edmunds.

—A correspondent writes:—"The three weeks frost broke up a few hours ago. The thermometer, for something like that period, has indicated many degrees of frost. The ice in our ponds and canals was 10 in. thick, and our pumps and water-works pipes were frozen. To-day (Dec. 28) I have walked round my garden, very carefully, for there is still ice like glass two or three inches thick on the paths. I expected to lament many favourites destroyed, but I find my new Strawberry beds green as emerald; Couve Tronchuda and Spinach with not a soddened leaf; All the Year Round Lettuce, sown in September, perfectly sound; leaves green, and not yet fallen from several pyramidal Apple and Pear trees; bush Roses still full of leaf, and many half-grown buds not drooping; many standard Roses full of leaf where I expected to find the heads destroyed; and, on the house wall, facing the east, Belle Lyonnaise, Climbing Devoniensis, and Maréchal Niel, still covered with unfrozen foliage. Some scores of Rose cuttings, planted like Gooseberry slips, in the open ground, last September, seem perfectly uninjured—a curious circumstance, as I have for years tried to raise Roses on their own roots, under glass and otherwise, and never could succeed. My garden is fully exposed on all sides. I reside on the east coast of Lincolnshire, on a tidal river, five miles from the sea. The only explanation, to my mind, is that we have had no east wind. The wind, north-west, has been very often a dead calm, and the ground, for the last week, has been more than 1 ft. deep in snow, but there were many days and nights of severe black frost before the snow came."

Boston.

W. C.

Paraffin as an Insecticide.—This is one of those remedies that appear to me to vary in their effects according to the manner in which they are applied. We have lately been using Paraffin freely for washing plants, and also houses that have been badly infested with meanly bug, mixing it in the following manner, viz., a wineglassful to three gallons of water, with a good handful of soft soap, mixing altogether until worked into a froth. Then we have a copper of soft water, boiling hot, and mix the quantity required, which then mixes without difficulty. If for washing glass houses, apply it with a garden engine with force, and extra strong if no tender foliage be in the way. If for plants, do not exceed the strength named, and apply the mixture carefully with a syringe. I feel sure, if every part be reached, that a clearance of insect pests will be the result. If mixed with cold water, and the plants be dipped in it, as some state, there is no wonder if the cure prove worse than the disease.—J. G. L.

NOTES OF THE WEEK

The Cape Pond Weed.—Notwithstanding the severity of the weather of late, numbers of flowers of the *Aponogeton distachyon* may still be seen in a stream of water in Mr. Parker's nursery, Tooting. Although the water was frozen over to a considerable depth, neither the plants (which are in pots) nor their flowering properties appear to have sustained the slightest injury, and should the weather continue as mild as it is at present, hundreds of blooms will soon be opened.

Hardiness of Iris alata.—This charming winter-flowering *Iris* (lately figured in THE GARDEN) commenced to expand its blossoms in Mr. Barr's grounds before the late severe frost set in. Blooms of it, which were then half opened, have withstood the severity of the weather without injury, and are now expanding rapidly, and will soon be fully developed. This proves that, in addition to this being one of the handsomest of the winter *Iris*es, it is also one of the hardiest, and, on this account, it is needless to say, the most valuable.

Angreum sesquipedale.—Plants of this charming *Orchid* are grown in Messrs. Veitch's nursery, Chelsea. A specimen of it at the present time bears about twenty buds and partly-expanded blossoms, whilst the plants themselves, owing to their green and healthy appearance, are far from being unattractive, even when not in bloom.

Daphne indica rubra.—This has become comparatively a scarce plant, even in nurseries; it is, therefore, satisfactory to find a good stock of it in Messrs. Veitch's nursery, consisting of compact little plants, in 4-in. or 5-in. pots, each shoot of which is furnished with a good truss of well-coloured, agreeably-scented blossoms. So fragrant, indeed, are they, that a few small plants of this *Daphne*, even in a large conservatory, are sufficient to fill the house with a perfume, the sweetness of which is equalled by that of but few other plants.

A New Fern.—Mr. Williams has, in his nursery at Holloway, a very distinct *Nephrolepis*, which promises to be of great value for hanging-baskets in the conservatory. It has long, arched leaves, and produces large masses of thread-like rhizomatous roots, from 8 ft. to 9 ft. long, which depend in a graceful manner from the baskets.

Aucubas at Christmas.—When well furnished with berries, and the latter well coloured, few berry-bearing plants are more handsome in winter than *Aucubas*. They are quite as easily grown as *Solanums*, and, on account of their stiff green foliage, are much more effective, especially when grown in the form of dwarf, bushy plants in 6-in. pots, as may now be seen in Messrs. Veitch's nursery, Chelsea.

The Giant Christmas Rose.—The blooms on established plants of this fine *Hellebore* in Mr. Parker's nursery, Tooting, are this year finer than we have ever before seen them. They have been slightly protected from rain and snow by means of lights or hand-glasses, which keep the blooms clean and pure, and also encourage them to develop themselves more perfectly than they otherwise would do.

Hardy Plants in Flower in Nottinghamshire.—There are certainly not many gardens in the midland counties where one may gather flowers on New Year's Day from the borders, and that too, when the thermometer marked 25° of frost on Christmas Day. Here there is a large clump of the giant Christmas Rose with two and three blooms on a stem, that has been in bloom for a month past. There are also several other charming bluish-coloured *Hellebores* in bloom, a few herald blooms of *Hepaticas*, white, blue, and H. angulata, several beautiful *Primroses*, hybrids from the large mauve *Primrose* now known as *P. grandiflora*, and of the rich crimson *P. auriculata*. *Polyanthuses* were blooming well before the frost, and will soon be sending up their heads. I know where I could find the first purple bud of the early spring *Cyclamens*, whose great rich crimson-lined leaves lay hid unhurt beneath the snow.—FRANK MILLS Bingham, Notts.

Trial of Hellebores.—Mr. Barr has now in his nursery at Tooting perhaps the largest and most complete collection of *Hellebores* ever got together. It comprises every variety procurable both in the United Kingdom and on the Continent, and each kind being well planted on raised and otherwise prepared beds, their correct names and synonyms will be easily determined. At present there is in bloom a large quantity of *Hellebores altifolius* or *maximus*, and a beautiful variety named *H. niger minor*. The latter possesses foliage of a lighter and more pleasing shade of green than that of any of the other kinds, and its flowers, which have been produced in abundance since early in November, are large and of snowy whiteness, and are admirably adapted for bouquet making. Though the plants in ques-

tion have had no protection afforded them, only such flowers as were fully expanded when the frost occurred have suffered any injury. As the different sorts come into bloom, they will be classified; and if this be done (as no doubt it will be) as efficiently as the *Daffodils* were in the same establishment, good work will be effected.

Eupatorium Weinmanni.—This is largely grown in Mr. Wills' nurseries, Fulham, for supplying out blooms in winter, which it does in abundance. Its leaves are smoother than those of *E. ageratoides*, and its flowers are whiter. It is also well worth growing into specimens for flowering in the conservatory.

Masdevallia polysticta.—Though the flowers of this *Masdevallia* are comparatively insignificant, they are, nevertheless, very pretty, and are produced in greater profusion than those of any other kind. It is grown in quantity in the Holloway nurseries, where small plants of it, in 4-in. pots, bear, at the present time, as many as a dozen graceful little flower spikes, each of which is furnished with some five or six buds, or small, whitish, prettily-spotted blossoms that well repay minute examination.

Dwarf Poinsettias.—These are well grown by Mr. James, Isleworth, who propagates them from tops of plants late in the summer, and by good management afterwards succeeds in getting plants about 6 in. high in 5-in. pots, bearing fairly large heads of bloom and furnished with healthy leaves down to the pot. In this state they are exceedingly useful for small vases or for forming a front row in the conservatory. In the same garden large plants of *Poinsettias* are also grown to perfection, and, mixed with good plants of the double white *Azalea narcissiflora* and graceful racemes of *Euphorbia jacquiniæiflora*, they produce at the present time a grand effect.

Pilea muscosa among Orchids.—This free-growing plant is grown on the stages among the *Orchid* pots in Mr. Philbrick's garden at Regent's Park. It is planted out in the gravel along with *Panicum variegatum*, and, in this way, the gravel and pots are almost hidden, and more moisture is retained in the atmosphere than would otherwise be the case; therefore, besides the good effect produced, the *Orchids*, which are, as a matter of course, the first consideration, are benefited thereby.

Cyclamens and Tree Carnations.—These associate well together. They flower at the same time, and the same temperature and other conditions suit each equally well. Mr. James, Isleworth, grows them together in a small lean-to house, and, besides affording plenty of bloom for cutting, they also make a fine display for many weeks in the form of plants in pots. The *Cyclamens* consist at present chiefly of a rich dark purple or magenta-flowered kind and a pure white sweet-scented one, and the *Carnations* are *Rose Perfection*, rosy-pink; *Miss Jolliffe*, flesh colour; and *La Grande*, scarlet. The large *Cyclamens*, so well known at the London shows, that come from Redlees, are quite equal to those of former years, and the same may be said of the *Cinerarias*, *Pelargoniums*, &c.

Oncidium Forbesi.—Of all *Orchids* now in flower in Messrs. Veitch's nursery this is one of the most attractive. Plants of it, bearing gracefully arching spikes of golden-edged, chocolate flowers, are introduced among other plants on the sides of pathways with excellent effect. In the same houses are also finely-flowered examples of the well-known *Lycasta*, *Skimacri* and its charming white variety, also a remarkably fine variety of the showy *Odonoglossum Hallii*, one plant of which bears two graceful spikes, each furnished with about a dozen large and handsome blossoms. To these may be added the pretty white *Laelia albida*, and that most useful of all *Lady's-slippers*, *Cypripedium Sedeni*.

Betonica (Betony).—In woods and thickets all over Europe and Northern Asia these plants are among the most attractive of the extensive Labiate Order. One species, *B. grandiflora*, a handsome plant, is one of the most valuable subjects that could be found for the wild garden, growing anywhere in free soils, in copses or shrubberies, among the dwarf herbaceous plants or Grass.

Bocconia (or Macleaya) Cordata belongs to the Poppy family, but is wholly distinct in aspect from any other herbaceous plant grown, and one of the most valuable for the wild garden, living, as it does, in almost any soil, but attaining the proportions of the stately Siberian herbaceous plants when in free and good soil. In open glades in woods it would be a great ornament, especially if planted near deep accumulations of leaf soil.

ANSWERS TO CORRESPONDENTS.

Questions.

Substitute for Asphalte.—Allow me to state in reply to "H. M." (p. 556, Vol. XIV.) that an excellent dry path for gardens may be made as follows: After removing 3 in. or 4 in. of the surface soil, put in a layer of broken stones or bricks, road metal size, and fill in the interstices with smaller stones and sand mixed with as much coal tar as will moisten it and no more. It should then be well rolled. After the lapse of three or four days it should have a coating one-eighth of an inch thick of sand and coal tar, made as dry as possible, and again rolled, after sprinkling the surface with dry sand to prevent the mixture adhering to the roller. In ten days it will have set sufficiently hard for use.—T. B.

—"H. M." (p. 556) will find the following directions for laying down garden paths with coal tar and gravel, useful:—Procure a quantity of common gravel as free from dust as possible, put it under cover and turn it frequently till quite dry; mix this with tar, just sufficient to wet every pebble, and no more; do a little at once, and turn it over till well mixed. Make the bottom of the walk quite solid, and then lay on the mixture from 2 in. to 5 in. thick. Press down with a heavy roller and sprinkle a little fine gravel on the top, then roll occasionally till set. Fine weather should be chosen for the operation.—J. D., Perth.

Baits for Field Mice.—"J. M." says (Vol. XIV., p. 573) that he has caught all kinds of mice by baiting his traps with Barcelona nuts. Does he mean to say that he has caught the short-tailed field mouse or bank vole with this bait? Barcelona nuts are almost irresistible to the common house mouse and the long-tailed field mouse, and I have caught two of the three species of shrew by baiting with cheese, but I have never succeeded in catching either of the two short-tailed species in any kind of trap at all, and these are the two species most destructive to plants growing on rockwork. They do not destroy bulbs, but graze off the young succulent shoots of various species of Iberis and many other rock plants as clean as a sheep. These mice constitute the principal food of the common barn owl, a bird which may be said to spend its whole time in destroying vermin, but which is ruthlessly slaughtered by sportsmen, gamekeepers, farmers, and others. Every man who has a barn owl ought to be punished.—H. HARKUP CREWE, *Drayton Beauchamp Rectory, Tring.*

Nettles Under Trees.—"E. F." (p. 586) should keep the Nettles about which he enquires, mown down to the ground five or six times during the growing season; that prevents their seeding, impairs root action, and ultimately wears them out.—R. GREENFIELD.

Charcoal Burning.—The readiest way of making charcoal is to cut up the wood into lengths of about 2 ft. 6 in. or so, and if large, split it into quarters, and lay it somewhere to dry, after which it will be in a fit condition for burning. In stacking it preparatory to this, a stake should be driven into the ground, around which a heap of shavings and small sticks should be piled, and against this the wood should be placed close on end in a regular direction, allowing just sufficient room between each piece for the fire to travel freely. The stack may consist of one layer or two, according to the quantity to be burned, but it is better to build it in the latter way than to have the circumference large, as it is not only easier for covering up, but can then be charred with greater regularity. As soon as the stack is formed, it should be covered in with a good thickness of straw, except just 2 ft. or so of the middle left open to light it and set the fire going. The straw on, the next thing is to cover it with from 9 in. to 1 ft. thick with soil or sand; when all is ready apply the match and set the fire blazing. Once this gets a fair hold of the wood, the middle must be covered in, and holes pierced with a stake through the soil to let out the smoke and draw the fire to the sides till it gets hold of the mass, when smaller holes should be made and the others stopped, the object being to prevent any flame or a too rapid combustion. It often happens that the wind will drive all the fire to one side, to obviate which the holes there should be closed, and encouragement given by opening others in the opposite direction to draw it there, that the charring may be regular throughout. To prevent waste by over burning, much watchfulness is necessary, as if the fire gets too free vent anywhere, the wood is soon consumed to ashes, instead of being simply blackened through without losing much of its bulk. When the charring is complete, the fire may easily be smothered out by patting the soil close with the back of a shovel, so as to prevent all escape of smoke, when, after a day or two, the heap may be uncovered and the charcoal withdrawn.—S. D.

Names of Plants.—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimens as complete as possible, i.e., both stem, leaves, and flowers, and fruit, when possible. To carefully pack them in gutta-percha tissue, or other impervious material which will prevent evaporation. Not to send varieties of popular flowers, such as *Fuchsias* or *Pansies*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—R. S. G.—Mistletoe is sometimes spelt Missetto, but Bentham (Handbook of the British Flora) spells it Mistletoe. As to your second question, deodorise with peat, charcoal, ashes, or dry loam. *K.*—*Hovea acutifolia*, a leguminous shrub from New Holland.

Smuts from Furnace Chimneys.—I have in my garden a group of houses heated by a saddle boiler, the chimney to which is carried up the usual height. The blacks from this chimney are a constant annoyance, and cover the glass roofs with smuts. What is the best way to remedy this difficulty?—A. E.

Early Melons.—Will some one recommend me two good suitable Melons for my earliest crop (scarlet and green fleshed). I intend to grow a few plants of my first crop in a span-roofed pit, also two sorts of the above named, suitable for a frame, to come in as a second crop.—J. W.

Lamp Heating.—I have erected a small greenhouse and I am anxious to keep frost out of it, I have, therefore, purchased a paragon stove in which I am burning paraffin oil which has a strong smell, and I fear it will be injurious to the plants. Is there any other oil that would do equally well and be without smell?—S. R.

Tuberous Tropaeolums.—I have a tuberous *Tropaeolum* making long slender shoots, but a friend tells me that I shall not get it to blossom, he having tried them several times but could not succeed. Will some of your readers kindly inform me if it requires any particular treatment or temperature, and if it should be watered freely.—W. B. B.

Trellis Shadings for Glass Houses.—These are largely used in France, where they are called "Claires pour ombre." Such screens are very convenient and suitable for all kinds of close shading, and they would also protect greatly from hoar frost. The links are made in France of galvanised iron, but in this more moist climate, and where the air and drip are impregnated with sulphur from coal and smoke, it would be advisable to use brass clips and rings. The price in Paris is fr.4-50 per square metre, equal to 3s. per square yard. Does anyone make them in England?—G. G.

Plants for Carpeting Bulb Beds.—I want to carpet my bulbs (*Crocuses*, *Scillas*, *Snowdrops*, *Anemones*, *Tulips*, *Gladioli*, *Lilies*, &c.), and the information I seek is which are about the best plants for the purpose, with a view (1) To their own beauty of flower and winter foliage; (2) To their fitness for the particular sort of bulbs below by not obstructing their growth when they appear above ground, and by their having surface roots that will not impoverish the soil for the bulbs; (3) The Saxifrage are often mentioned in this view, especially the Mossy section, but there appears to be many varieties of these, and I should like to know the best named sorts; (4) I do not want to know of many carpet plants for this purpose, but I should feel much indebted for the names and characteristics of a few (not Saxifrage exclusively), and if they afford some variety of colours in flower and autumn foliage, the latter being the more valuable, not only to me, but to the many like me, who dislike the bare places as much as they dread the frequent consequence, the descent of the destructive spade, where now our bulbs are so commonly found.—J. S.

Presentation to Mr William Sutherland.—Mr. William Sutherland, who has occupied the position of general nursery manager for Messrs. Ker, of Liverpool, during the last five years, was entertained to a complimentary dinner on the 20th ult. at the Aigburth Hotel, by a large number of the leading gardeners of the district and other friends, on the occasion of his relinquishing his duties with Messrs. Ker, of Liverpool, to undertake a similar post in the nurseries of Messrs. Ireland & Thomson, of Edinburgh. After the dinner, Mr. Sutherland was presented with a handsome gold watch and appendages by Mr. Hinds, of Otterspool, on behalf of the subscribers. The watch bore the inscription, "Presented to Mr. William Sutherland by Liverpool gardeners and friends, as a token of their esteem and respect, Liverpool, December 20th, 1878."

New Canadian Poplar (*Populus canadensis* nova).—This is one of the best and most useful hardy deciduous trees which we possess. In the first place, it is the most rapid growing of all our hardy trees. We have ourselves seen in the Knap Hill Nursery plants which have made 10 ft. growth in a season well furnished with branches. This will give some idea of its rapid development. It is, moreover, a tree well adapted to London, and may be seen in luxuriant health in the plantations on the Thames Embankment at Chelsea. From the treatment to which it has been there subjected, it is evident that it will bear any amount of pruning, so that it may be kept to any size or form required. It is probably the best tree we have for planting in the smoky towns of the manufacturing districts in the north of England. Its nearest affinity is with the black Italian Poplar, and, in fact, it may be described as a very much improved form of that variety, possessing greater vigour of growth, as well as larger leaves, which are retained fresh and green till a later period of the season. It is, in fact, in every way an improvement on that well-known and useful sort, and as a screen tree has no rival.—"Gardeners' Chronicle."

OBITUARY.

JOSEPH DALE, for many years gardener at the Middle Temple, died suddenly on the 31st ult., aged 65. Mr. Dale, like the late Mr. Samuel Probyn, was a most successful grower of *Chrysanthemums*, and was the author of a little book on their culture.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

TREES, SHRUBS, & WOODLANDS.

TREES "OF THE FUTURE."

At this time, when a new year is dawning on us, many people "take stock," as it were, not only of affairs in general, but also of their gardens in particular; and duly note down the acquisitions of the year, and the experiences gained therein. In planting trees, it is to the future we must look, and it is with regard to this point I would particularly direct attention. During the last twenty-five years, what a vast number of trees have been introduced and planted in our gardens! and of these the greater number without doubt are Conifers; so much so that those who come after us will probably term our age the "Age of Conifer planting," just as we now regard the end of the sixteenth and beginning of the seventeenth centuries as the "Elm-planting age." The question then comes, how far do we think we shall surpass the efforts of our forefathers, who have bequeathed to us such grand Elm walks, Lime avenues, and Yew hedges, as evidence of their skill and foresight? or how far shall we fall short of the results they have attained? Without disparagement to ourselves, I think we must allow that they have, in their line (that is, in planting avenues of trees that come to perfection in this climate), reached a standard of excellence we cannot hope to surpass; but, on the other hand we can safely say that, for grouping, or general effect, we have planted trees that will earn for us that gratitude given so freely, if at all, by posterity. What proportion our successes will be to our failures is altogether another question, and one that I fancy could hardly be answered favourably.

As long ago as the days of Horace we were told that we are more affected by what we see than what we hear; that we trust our eyes rather than our ears; and so it is now. We plant for the sake of immediate effect; or, struck by the infantile beauty of some new seedling tree or shrub, we cram our gardens, parks, and plantations with material that in the end proves unsatisfactory. In this respect, I daresay our forefathers would have been no better had they had the opportunity; but we may gain an advantage over them by ascertaining, as in these days of research we are fully able to do, what is the exact effect of the trees we plant when seen in their native haunts. Artists, botanists, photographers, explorers, in turn, give us the result of their labours in books, which are accessible to all, and the most incredulous eyes can hardly disbelieve what the sun has printed for us in black and white, even if the coloured sketches of the artist be distrusted by those who have been disappointed at such hands in days gone by. The only real disadvantage we labour under, is that we cannot tell positively how far these newly-introduced trees will reproduce in England the beauty they show when in perfect growth at home; but even in this case if we study with any degree of closeness their native habitats, we shall, in imitating them, be successful, both as regards present effect and future satisfaction.

Of all the trees introduced in modern days, none has been planted more universally than the Wellingtonia gigantea, and I venture to say that few are less worthy of such extensive planting. No doubt it is the fact of its vast size that has created such a desire for it, but does that make it the more generally suitable? Let us see what it is in its own country! A huge bole, towering up into the sky—a trunk, garnished with a few scanty branches, at rare intervals, high above our heads, that seem as if there to show how small they are in proportion to the trunk. The foliage is so scanty that the mid-day sun is robbed of little of its strength by the tufted branchlets even where they hang the thickest, and the whole grove more resembles a gigantic array of scaffolding poles half stripped

already for the builder, than a collection of the so-called grandest trees in Nature. Planted in a close avenue, like a French allée of Poplars, or as a single finger post that makes, as it were, a mighty gnomon in Nature's sundial, it is well placed indeed; but should it not attain its full stature in this country, where will any charm be found in it when it outgrows its youthful richness of foliage? It is well-known now that Australia can show a tree that towers up to a height of 480 ft. It is needless to say that it is only in the richest soil of a sheltered valley in the Australian Alps that *Eucalyptus amygdalina* attains such an enormous height, but it has one advantage over the Wellingtonia, namely, that when isolated, it forms a branching, round-headed tree, in shape approaching the Wych Elm, and only runs up with a long, bare stem when crowded up among other trees of like growth. If this prove hardy, and it is not very unlikely that it may be so, it no doubt will be largely planted by lovers of the gigantic in coming years.

To any one fresh from Californian coasts it does seem a little strange that a tree so beautiful and so valuable as *Taxodium sempervirens* should be so rarely seen here. In its native country it forms vast forests that, till lately, stretched for hundreds of miles on the north-west coast. Its timber—the Redwood of commerce—is valuable in many ways, and is largely used for building purposes because it burns with difficulty. In stature it does not fall more than 100 ft. short of its kinsman, the Wellingtonia, and is incomparably the more beautiful tree when full grown. It has this peculiarity, that it only thrives in the belt of land that stretches inland five miles from the coast, and on that windy shore will not grow within a mile of the sea. This is what has probably caused it to be neglected; but, in an island like ours, where a large tract there must be suitable for its growth, where it would escape the severity of inland frost and luxuriate in the cool dampness of a sea fog, such as it gets at home. Planted singly it is inclined to branch too much, and requires pruning to make it shoot up into a tree when young; but its extreme rapidity of growth, and its beauty when old, to say nothing of its value as timber, should make it a favourite with all who can plant it in the neighbourhood of the sea.

Another tree, not far distant of kin, that shoots up 200 ft. into the air, and lights up the mountain sides of Japan with its bright green, pendent branches, *Cryptomeria japonica*, has the unusual property of looking beautiful in all stages of growth, and its wood is valuable for panelling, as all Japanese travellers know who have enjoyed the peculiarly sweet scent it gives to a room. This tree, in its native country, braves the violence of a typhoon, and, when full grown, will probably stand our westerly gales better than trees that grow in sheltered inland valleys. Like the Wellingtonia, it shows to greatest advantage when planted singly or in a close alley. In Japan there is an avenue 30 miles long closely planted with this tree, so much do they admire it. As an old tree its branches, first pendent and then gracefully recurving at the tips, give it a character so marked as to suggest its idea carried out by Chinese and Japanese in the curving roof of their pagodas, which seems to have been borrowed from this source.

Two trees there are that are the most prominent as well as the most common among Japanese trees, and give that air of peculiarity which all have remarked; and yet, though hardy, they are but little planted in this country, because, in their young state, they are undistinguishable from the Scotch Fir, and these are *Pinus densiflora*, which when full grown, is a very distinct and handsome tree, with a massive, rounded contour; it surpasses in size and beauty the Italian *Pinus Pinea*, and is, in its native country, of far more rapid growth. This should be planted as an isolated specimen tree, and will thrive under the same conditions as the Stone Pine. The other is *Pinus Massoniana*, a tree still more hardy, and of the wildest and most original growth, so like a Scotch Fir in its young state that it is not surprising it should be little known or planted; but as soon as it attains to middle age, its eccentricity of growth begins to show itself, and in old age it assumes the shape of a Cedar of Lebanon. Planted thickly in clumps, this tree will, in the space of a lifetime, reproduce something of Japanese quaintness in our parks; and to those who plant "for the future," this will in the end repay their patience, and prove quite unlike any other species of *Pinus*.

Before making any remarks on other members of the great Conifer family, there are yet two of the true Pines that must not be overlooked. *Pinus macrocarpa* (or *Coulteri*) is a Californian tree that certainly will gain much admiration in days to come. Perfectly hardy, exceedingly large in leaf, branch, and fruit, it is handsome in every way; its branches are very wide apart, and the branchlets few, so as to give space to show off the size of each. Like *Pinus insignis*, it is a rapid grower, but is, if I am not mistaken, a far superior tree in every way, and its hardness makes it deserving of a place in every well-furnished garden where there is room for a large tree. The last of this family which I will mention at present is *Pinus Laricio*. Its beauty in its native Corsican forests and its value as timber make it so desirable a tree that, at the risk of being tedious, its merits should be extolled. Introduced a hundred years ago, it has proved itself thoroughly hardy in all parts of the kingdom; and, though well known, has not yet nearly reached the favour it merits. Like the Scotch Fir and the Larch, it is deserving of universal growth.

E. H. WOODALL.

ORNAMENTAL FORESTRY.

Few subjects present a better field for the display of taste than the planting of trees, and there are very few situations in which they may not be made highly ornamental as well as useful, for when they are chosen and arranged with taste, they give variety to the most tame and level country, charm to the waterside, beauty to the slopes, both from the trees themselves and the shadows which they cast, and relief to the naked hill, upon whose summit "the labouring clouds do often rest." What thinning is to the overcrowded plain or valley planting is to the hill—the one relieves the darkness, and the other the bleakness of the scene. In ornamental forestry, as in landscape gardening, the works of men eminent in their day and generation have fallen into disrepute from the ignorance and ambition of their followers and imitators. Pontey pruned, and his successors lopped unmercifully; Brown substituted curves and sweeping outlines for the straight lines of his predecessors, and his imitators gave a meandering course to every stream and piece of made water, and a serpentine form to every pathway and fence. Whoever aims at producing the best effects from his planting, must study closely the habits of the trees with which he operates, their rates of growth, the dates of their maturity, the periods of their decay, their varieties of tints, and their adaptability to the soil, situation, and climate. In striving to produce grandeur he must adhere to simplicity; in seeking to attain variety he must avoid incongruity, for while a reasonable amount of variety never fails to please, too great an admixture bewilders, and too regular a succession, either of tints or forms, destroys the whole spirit of planting. The carrying out of all minor details, such as the planting of particular quarters and detached parts, will be found comparatively easy, but skill and judgment are required to blend the seemingly unconnected parts into one harmonious whole.

The perfection of the planter's art will be as apparent in the skill which he displays in concealing deformities, as in that shown in developing beauties; and while in his variety he may approach intricacy, and thereby arouse curiosity, he must maintain throughout his composition, both connection and continuity. His tints, like those of the painter, for whom he prepares the picture, should consist of both warm and cool. If in autumn he can display them as wild as those of the evening clouds, to which his planting will form a natural and appropriate foreground, so much the greater will be his success. In revealing beauties or concealing defects, he must on no account interfere with freedom or extent, but so blend his masses of plantation and his open grounds, as to hide the limits of both; thus the extent of his work will not strike so much by its vastness of dimensions, as by the nobleness of its effect, and, as it is the experience of its utility which gives the enduring charm to beauty, so, in the choice of his trees, he should select those which, after they have gratified the present generation of beholders, will greatly benefit posterity. In surveying plantations we often meet with scenes which strike us by their incongruance or unfitness to the locality; such,

for instance, as the lean outline which a few scattered Poplars or Firs impart to a grove in the immediate vicinity of a noble-looking mansion. The effect of their unsocial tops is much the same in any considerable mass of round-headed trees. Another, is the insignificance imparted to a house of any pretensions when it is flanked by trees which rise very much higher than the building itself, for, as the trees continue to grow, the house appears to sink. A third is the effect of a grove of Firs upon an open common, or in any situation where they can be browsed by cattle; for as they lose their lower sweeping branches, their ornamental effect is completely destroyed. The mutilated forms of closely-pruned Elms, with nothing left but bare trunks and tufted tops, become permanent blots upon the face of the landscape, for if, after such treatment, the side branches are again allowed to grow, the tops decay, and it is only by subsequent pollarding that their lives can be saved. Whilst the ornamental planter aims at the production of breadth of light and shade, he should bear in mind that density is effective mainly as a contrast, and it is by no means the thickest grove or the most compact tree that yields the greatest amount of pleasure to the beholder. Those trees which present fairly open heads, with alternations of canopy and recess, and consequently of light and shade, give the greatest variety to a plantation, and this may be increased to an almost endless extent by a choice of trees suited to the configurations of the ground. In the vicinity of the mansion beauty and picturesqueness must sometimes yield to comfort and convenience; but as the planting recedes it may pass from grace to wild luxuriance, until at last it attains the freedom of a forest.

The continuity which is so essential to the completion of a landscape may sometimes be maintained by the selection of species of trees which adapt themselves by form and outline to those of the adjoining masses of plantations. Thus, Alders as they grow old so much resemble Oaks that a superficial observer often fails to detect the difference; hence their utility in keeping up the appearance of a continuance of Oak plantations in soils too wet for the Oak to flourish. The Alder, too, succeeds in some cold-bottomed land, and upon some exposed sites where the growth of the Oak would be very slow and its appearance stunted; and as the fastest-growing tree is nearly always the most graceful and ornamental, a vigorous Alder, or even a well-grown Willow or Poplar, is preferable to a languishing Oak. In clearing for the sake of giving variety and effect to woods of large extent, it is too much the custom to sweep away the whole of the underwood, as well as bushes of all kinds, so that all bonds of connection between the remaining groups are completely severed. This gives an appearance of abruptness to the planting, and a certain degree of isolation to what is left. Whatever tends to diminish abruptness softens the whole scene, hence the beneficial effects of thinning out the front lines of dense woods, where such margins are much in sight and fairly sheltered; the detached trees break up, or very much soften the approaching gloom. But in such situations very light and elegant trees would be, to some extent, out of place. One of the finest effects produced by plantations is observable when, from the valleys and plains below, the trees appear to climb the heights, following the line of the crest and the direction of the spurs, not in narrow belts, but in broad masses, the different species gradually intermixing, and entirely changing with the heights, from the luxuriant Oak, Elm, and Ash below, through zones of Beech, Sycamore, &c., to the Pine-crowned summit. Such woodlands will appear either to mount from below or flow from above, according to the situation of the greatest breadths of plantation and the directions in which they radiate; and the occasional openings, with their warm nooks for the homestead, and their enclosures for well-sheltered, arable or pasture lands, will give a variety and a richness to the country which is, if not unattainable, at any rate unobscurable to the same extent, in more level districts. These occasional openings are also very effective in marking the degree of activity in any well-wooded and rising ground.

A. J. BURROWS.

The Red-berried Elder.—We have several plants of this Elder, about 8 ft. high and as much through. It is quite hardy here; even

the late severe weather does not seem to affect it, while Bays, Portugal Laurels and Laurustinus are quite blackened. When in fruit I consider it to be one of the best shrubs which we have. There is nothing that equals it in the shrubbery during the autumn. The berries hang in clusters like bunches of grapes. As Mr. Grieve states, birds are very fond of the berries, and devour them with as much relish as they do currants.—A. McINTOSH, *Laxton House, Berwickshire.*

ORNAMENTAL SHRUBS IN THE SOUTH OF IRELAND UNDER SEVERE FROST.

As during the three weeks immediately preceding Christmas we, even in this usually mild and temperate locality (the seaboard of the county of Cork), experienced the severest weather, and the greatest intensity of frost, that has been known here for forty years, the thermometer having on more than one night fallen as low as 17° Fahr., thus showing 15° of frost, when 5° or 6° is the most we usually experience, I think that an account of the way in which some of my more uncommon and doubtfully hardy shrubs have withstood this ordeal may not prove uninteresting to those of your readers who admire and cultivate that class of plants. The Veronics, which were nearly all either killed altogether or down to the ground in the severe winter of 1860-1, when nothing like the degree of frost was reached that has this winter been registered, have this year, I am happy and surprised to say, passed altogether unharmed; even some small cutting plants of new varieties, received by post from France late last autumn, and planted out in a border at the end of my garden without any protection, are uninjured, and the variety *V. Girdwoodiana*, supposed to be decidedly more delicate and tender than the others, and which I had lost more than once previously, is also unharmed; *Pittosporum crassifolium* had its young top shoots only browned; *Coprosma lucida* and *Cunninghami* were only very slightly injured; *Banksia australis* is uninjured; *Eurybia lyrata*, *ramulosa*, and *Traversi* have been punished, the first and last named most so; they look as if they would lose most of their leaves, but the wood seems uninjured, and will, I think, break again; *Melaleuca hypericifolia* and *Pomaderris elyptica* seem killed; *Escallonia arguta*, a small, young plant is uninjured; the silver variegated form of *Fatsia japonica* usually known as *Aralia Sieboldi*, has passed uninjured, while the ordinary green form is considerably browned; *Berberis nepalensis* and *trifurcata*, usually considered tender and requiring the protection of a greenhouse, are quite uninjured, as is also *Thuja Donniana*, the beautiful Fern-leaved form which I have never seen planted out save in this neighbourhood, as even at Exeter it was grown in tubs which were wheeled into the Camellia house in the winter; it is apparently, however, much harder than it was thought to be. *Aralia Schoefleri* and *quinquefolia* are a good deal injured; *A. Standishi* and *Abeli* not at all. *A. mexicana*, *heterophylla*, and *Cunninghami* have suffered, but not seriously. *Olea exelsa*, tops of young growth destroyed. *Garrya macrophylla*, which is supposed to be tender, and is grown in the temperate house at Kew, is quite uninjured, though the superincumbent weight of this heavy snow fall in November, broke the centre out of my large specimen of this fine-foliaged shrub. *Griselinia macrophylla* (true) (the variety usually known under this name being really *G. lucida*) is perfectly hardy, whereas *G. lucida*, even against a wall and protected by fir branches, is much injured. Of the variegated *Phormium*, *P. tenax*, var., has suffered most, and is, I fear, seriously, if not fatally injured. *P. Colensoi*, beyond being beaten down by the weight of snow, does not seem to have suffered, and *P. Veitchii* is altogether uninjured and its leaves quite upright. *Embotrium coccineum* seems quite uninjured save a few of the older leaves turned brown. *Cupressus Corejovana* the true funeral Cypress so seldom met with, and supposed to be only half hardy, is quite uninjured, and seems perfectly hardy; *Enonymus ambratus*, supposed to be tender, is quite uninjured; *Cistus vaginatus* is a good deal browned, but will, I think, survive; *Brachyotum corymbosum* and *Newelli*, though against a wall, have lost nearly all their leaves, but their stems seem uninjured; *Ceanothus africanus* is seriously injured, if not killed; *Podalyria straciiflora*, *biflora*, and *setacea* are much injured, but will, I think, survive; *Choisya ternata*, which is usually supposed to require the protection of a wall, planted out in the open shrubbery, is quite uninjured, and may be considered perfectly hardy; *Aralia trifoliata latifolia* is much injured, but will, I think, survive; *Genista foliolosa* is a good deal injured; *Escallonia coquimbensis* is uninjured; *Donodonea Burmanni* and *viscosa* are a good deal browned, but the distinct and pretty *D. Boroniifolia* seems quite uninjured; *Abutilon* or *Sida vitifolia* has suffered, but not seriously; *Plagianthus pulchellus* seems quite uninjured, and *Benthamia fragifera* is also, contrary to my expectation, unharmed; *Viburnum Awakurki* is a good deal browned, and the foliage much discoloured but not seriously injured. I am sorry

to be obliged to confirm M. Carrière's opinion in the "Revue Horticole" for December 16, that the beautiful and most distinct *Chimborazo Pampas Grass* (*Gynerium jubatum*) is much less hardy than the other members of the family known to us, all the tops of the shoots of my plant being much injured, whereas the other varieties are quite unharmed. The *Apongeton distachyon* in my pond has not withstood the severity of the weather by any means so well as in Mr. Parker's nursery, all sign of blossom having disappeared, and even the foliage ceased to float on the top of the water as it usually does.

Belgrave, Queenstown.

W. E. GUMBLETON.

GOLDEN-LEAVED CHESTNUT.

(*CASTANEA CHRYSOPHYLLA*.)

FOR Lord Dacrie's information (p. 8) allow me to say that I found this Chestnut in the form of undergrowth, from 4 ft. to 6 ft. in height, in a forest of *Pinus insignis* to the south of Monterey, in Upper California. It has been found to the north in other localities in California, but I had not the opportunity of seeing it elsewhere. The few bushes of it which I saw were evidently not at home in the exceedingly poor, arid soil of that region, and the nature and condition of the soil will possibly account for their small size compared with that of plants of it growing in the rich, damp soil and moist climate of Oregon; there it is said to reach 40 ft. or more in height. It is probable that it was from the few scrubby bushes growing near Monterey that the first imported seeds were gathered, as Mr. Lobb, the collector, made Monterey his headquarters for a year or more. All the plants that I have seen of it in Britain resembled in size and habit those of Monterey, and the only exception I have heard of is the fine plant described by Lord Dacrie. The Tortworth plant has evidently found a suitable root run in the soil derived from the old red sandstone. I believe that all the species of Chestnut (*Castanea*) prefer arenaceous soils to others. The largest and healthiest plants that I have seen of the Spanish Chestnut were growing on the new red sandstone, but in the least oxidised strata. Nevertheless, I cannot think that a poor sandy soil will suit the examples of the golden-leaved Chestnut now in this country. It is a fine evergreen, but, if I am right in thinking that all the plants of it now growing in Britain have originated from the few at Monterey, it is doubtful if they will ever fully represent the ornamental character of the species. We must look for this in the hardier, better-constituted seedlings from the Oregon habitat, though with those we now possess it seems to be more a lack of stamina than of hardness. I have just examined a few plants and find that they have entirely escaped injury from the late severe and, to other plants, destructive frosts.

Elvaston Nurseries, Borrowash, Derby.

G. SYME.

CUTTING AND FELLING GARDEN HEDGES.

A HEDGE that is made of any plant that sheds its leaves in autumn, should never be cut in summer or autumn until after the leaves have fallen, unless in the case of those that are strong and vigorous, and that also have attained the full size to which they are required to grow, for the reason that nothing tends to weaken a deciduous plant more than a reduction of its shoots and branches whilst they are covered with leaves. There are two distinct purposes for which garden hedges are employed, viz., as a fence and as a screen. In the latter capacity they are often used for separating the useful from the ornamental departments, and for this purpose they need not be of such a substantial character as when used as a fence; they may therefore be kept cut much narrower, and whether composed of Beech, Yew, Privet, Holly, or Quicks, they need not from the first be kept headed back so closely as if required to branch out in a way to render them more impervious; on the contrary, they may be allowed to run up more quickly, simply keeping the sides trimmed up with no more breadth at the bottom than is necessary to allow the lower branches to get light enough to keep them healthy and thriving, a condition more likely to be maintained than if cut quite perpendicularly in the old-fashioned manner with the top square, an ugly and formal shape, and one in which a hedge can only be kept healthy when allowed to grow to a very considerable breadth from bottom to top. In the case of young enclosure hedges round gardens or orchards, the first consideration is to manage them from the commencement so as to secure a close, impervious bottom; this can only be accomplished by cutting the leading shoots down sufficiently low the first or second year after planting to cause them to break back near the base, and each subsequent year to shorten the strong, erect growths, enough to cause them to branch out still further; this will have the effect of throwing additional strength into the lowest branches that occupy a horizontal position. It is the undue haste

to get the hedge up to its required height too quickly, so often apparent the third and fourth year after planting by not cutting the upright growth low enough, that spoils half the hedges that are planted, especially when the lower horizontal branches are cut too closely in, a practice which tends to aggravate the evil by throwing undue strength into the upright growth. When hedges that are required for the purposes of a fence have got bare and naked at the bottom, in the way that such as are composed of Quicks will do if not well managed, they should be felled down to within 9 in. of the ground. When very strong they will require a saw or a light axe, which is better. The operator should stand on the lowest side of the fence, in the ditch if there be one, so as to be well under his work, severing the whole, both the strong and weak wood, in a slanting direction, with an upright stroke, by which means he will make a clean cut, and avoid splitting the stools in the way that results from cutting downwards, and which has such an unworkmanlike appearance, and is still worse in its effects by causing the young shoots to push weaker than when the stools are cut without splitting; but as there is much in the look of a garden hedge as well as in its answering the mere purposes of a fence, the felling and retention of an old hedge in the way described is not to be recommended if it be full of gaps where there is no living wood, for, although the defect may be in some measure made good by the introduction of young plants, as is often done to fill up the vacancies, still it gives the whole such a patchy look that it should never be tolerated in a garden where there are any pretensions to an orderly appearance; in such a case it is much better to grub up the old fence and plant afresh. It is often said that there is considerable difficulty in getting a young hedge to grow in the same place from which an old one has been removed, which is true when the exhausted soil is planted without any admixture of fresh material to renew it, but not if 6 in. of new soil, such as is procurable in country places from the roadsides, commons, or in any place where the surface spit can be spared where buildings are about to be erected, is added. Should these sources fail, street sweepings in the neighbourhood of towns, or road scrapings in the country will do mixed liberally with the old mould; 3 in. or 4 in. of rotten manure should at the same time be dug in. Many there are who manure liberally all the other plants they cultivate, and who never think of giving anything to encourage the growth of a hedge, which, not only in the first preparation of the ground, but for some years until fully grown, will well repay for liberal manuring, especially where Quicks or Holly is used.

T. B.

QUALITY OF WELLINGTONIA TIMBER.

In noticing several exceptionally fine specimens of *Wellingtonia* (p. 578), Mr. Berry speaks of its being yet premature to form any decided opinion as to the quality and durability of the timber of the *Wellingtonia*. But, concerning that, I think there is but little room for doubt, unless the tree is an exception to all others of a quick-growing character, for, taking a broad view of the subject, quality, which we may set down to mean strength, toughness, and durability, is present proportionate to the time required for its formation. The wood of quick-growing trees is light and spongy, conditions at once opposed to strength and lasting capabilities, and limiting its use for all but exceptional purposes. Although looked at upon the principal of small profits and quick returns, light timber, such as Poplar, may, on some descriptions of soil, be found as remunerative to the grower as the slower-growing, denser-wooded Oak, Elm, Ash, &c. I think we may take it for granted that the *Wellingtonia*, in common with other rapid-growing Coniferous or Taxaceous trees that have not yet in this country had time to give conclusive evidence of the quality of their wood, will be in no way different from other species of trees of which we have had enough time to judge correctly in this respect; in fact, the natural laws which govern the development of vegetable life in the formation of woody fibre, appear to point generally in one direction, which is that slow growth means comparative strength and durability. Of late years Sycamores, even of moderate growth, has been so much in request amongst machine roller makers that the price it fetches never could have been anticipated; the short-fibred, somewhat brittle nature of the wood renders it of comparatively little value for purposes where it will be subject to a strain, if for any length it is unsupported. To this, no doubt, coupled with the fact that the use for which it is now required was non-existent when trees which have attained any considerable size were planted, may be attributed the scarcity of its timber, for had it existed in anything approaching the quantity that some of our more generally used woods do, the particular purpose for which it is now employed could not have exceeded the supply. Good Red Willow appears to be almost equally in request than which nothing that has yet been found seems to do so well for

railway carriage and waggon brakes. This Willow, although, like the rest of its species, not hard or close in texture, is, nevertheless, so remarkably tough that it answers well for many purposes to which it is not often put; and, moreover, it grows fast on fairly good soil.

T. BAINES.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Beech Trees and Underwood.—Allow me to confirm Mr. Knight's statements (p. 579, vol. XIV). About a year ago I visited Floors, at a time when I was particularly interested as to the best subjects to form undergrowth beneath forest trees, and I was shown masses of *Rhododendrons*, *Yews*, and *Laurels* growing most profusely under the fine old *Beeches* and other forest trees that may be seen there; places that used to be naked plains some years ago, are now well furnished with underwood.—ROBERT GREENFIELD, *The Priory Gardens, Warwick*.

I forwarded the paragraph in *THE GARDEN* a couple of weeks ago, by Mr. Hossack, to a gentleman at Alderly Park in an excellent position to furnish information on the subject, asking him if he could corroborate the statements in *THE GARDEN* as to the luxuriance of the *Rhododendrons*, &c., under the *Beeches* there. He has just replied to my enquiries, and in his letter he states that the *Beech* wood referred to in *THE GARDEN* is called the "Beech wood," and contains some of the finest and odest trees in England; also that there are large quantities of *Rhododendrons* in the wood in question, but there are certainly neither *Rhododendrons* nor any other kind of underwood growing where the *Beeches* occupy the whole space overhead, nor any under the *Beeches* where they are growing thickly together. This is rather a different statement from that which said the *Rhododendrons* were to be seen growing, flowering, and seeding right up to the trunks of the trees, in the wood alluded to.—J. S. W.

Rhododendrons grow here under *Beech* Trees in the greatest possible luxuriance, and flower very fairly considering the shade to which they are subjected, and they also make one of the best covers for game. The *Yew*, *Holly* and common *Laurel* also grow very well, but they do not make such dense cover as the *Rhododendrons*. On the top of Boxhill, on the chalk, may be seen considerable numbers of fine *Beeches* growing amongst the Box, which grows quite as freely under the *Beech* as under Oaks, and it makes one of the densest of covers. It should be mentioned, however, that the Box in this case is indigenous. In this neighbourhood, another instance occurs on the chalk at the Denbies, where, in a rather dark *Beech* wood Box is growing very freely, and in this case it has been planted.—J. BURNETT, *The Deepdene, Dorking*.

Hardiness of Hydrangeas.—In *THE GARDEN* (Vol. XIV, p. 579) I find that Mr. Groom thinks that *Hydrangeas* require to be protected against severe frost. Permit me to say that *Hydrangeas* are much more hardy than is generally supposed, and that they are not so difficult as regards soil as is generally imagined. I have about one hundred plants in a border on the north side of my garden, planted in ordinary soil in front of some trees, *Lilacs*, and other shrubs, with the roots of which they struggle for existence. Nevertheless, without any protection, the *Hydrangeas* have stood over more severe winters even than that of 1871, and in summer are magnificent. I may, perhaps, add that a few were destroyed in Dec. 1870, but only those which were exposed to the sun in fine weather; those completely shaded escaped.—JEAN SISLEY, *Lyons*.

Trees and Foundations of Buildings.—A curious instance (says a correspondent of "The Builder") has lately come under my observation of the mischief to the foundations of buildings which may sometimes be caused by the roots of trees. In the case to which I refer attention had been drawn to an increasing settlement in the wall of a school, built some five years since. It was clear that something was wrong underneath, and so underpinning was determined upon. When the ample and well-executed footings and concrete had been examined it was discovered that the roots of a row of *Ontario* Poplar trees which stood in a neighbouring garden, some 20 ft. or 25 ft. distant, had worked their way down to the depth of some 5 ft. to 8 ft., and had completely disintegrated the concrete. The roots were mostly of very fine texture, some mere fibre of no greater substance than human hair, and a few larger ones as thick as a man's little finger, all entwined in the concrete. The soil was a soft clay, and an experienced horticulturalist assures me that although the roots of *Poplars* traverse strata which would repel other trees, yet they generally strike only to a shallow depth. In this instance the roots had devoured all the lime in the concrete in the lower part, which was crumbling away. The upper part, where no roots existed, was perfectly sound. Instances of strong roots throwing down walls are not uncommon, but I find on inquiring of experienced men that the insidious work of these distant trees is unusual. The new foundations, &c., have all been executed in Portland cement concrete to a considerably greater depth than before, and warning given to the occupants of the adjoining garden.

THE INDOOR GARDEN.

NIPHOBOLUS HETERACTIS.

UNFORTUNATELY this elegant and free-growing Himalayan Fern has been distributed under the erroneous name of *N. Heteractis*. We say unfortunately, because it is exceedingly difficult to displace a false name after it has once got into general use. This error probably originated in a slip of the pen, and although very slight in appearance, it so completely alters the meaning conveyed by the correct name that it is all the more desirable to correct it. The name *Polypodium Heteractis* was given by the late Professor Mettenius (Linnaea xxxvi. p. 140) to this plant, in allusion to the diversity of the rays of the starry scales with which the under surface of the frond is furnished. Further, it is by this character, as well as the difference in the size and shape of the fronds, that *N. Heteractis* is distinguished from the Japanese *N. Lingua*. These stellate scales are scattered over the dense indumentum or pubescence common to both species, and are quite visible to the naked eye, and they are probably imperfect sori. The fronds of *N. Heteractis* are larger than those of *N. Lingua*, being often 18 in. long, including the stipes, and the blade is more or less rounded at the base, instead of gradually tapering downward into the stipes, and it tapers into a tail-like tip. Altogether it is a more vigorous plant than its Japanese congener, and is a native of warmer regions, being found at low elevations in the Himalayan mountains, and also in Borneo. Mr. John Smith has somewhere given this Fern the name of *Niphobolus latus*, but I cannot find that this name was ever published with a description. Indeed, it does not occur in his last work on Ferns, and was probably given only to dried specimens which he at some period distributed. *Niphobolus Heteractis* was sent out by Mr. B. S. Williams, of the Victoria and Paradise Nurseries, in 1876, and the accompanying engraving was prepared from a plant in his possession.

W. B. HEMSLEY.

Eppe's Potting Soils.—Mr. Eppe, Vauxhall Station, has sent us various samples of peat, loam, and sand, of good quality. The peat is obtained from some high-lying land abounding in common Fern, or Bracken, and Scotch Fir plantations, the subsoil of which is dry

and sandy. From such a position as this the soil does not become sticky, wet, or harsh, from too much watering or drought, a circumstance not to be lost sight of when selecting soil for potting.

TEMPERATE OR INTERMEDIATE HOUSES.

I DOUBT if there be any kind of plant structure capable of affording so much real enjoyment as that which is commonly termed the temperate or intermediate house. In it we may assemble many and varied types of vegetation, as the temperature which has to be maintained therein will be sufficiently high to insure the well-being of many natives of tropical lands, whilst, at the same time, a considerable portion of the inhabitants of the cooler regions will be benefited by the slight stimulus which they will receive therein during the colder months of the year. The temperate house will range during winter from between 55° by day and 45° by night; it should not be more, and may occasionally be less without fear of injury. In this gentle warmth, Cinerarias, Cyclamens, Roses, Deutzias, bulbous plants, and a host of others may be forwarded into bloom. Palms, Ferns of many kinds, Aralias, and other fine-foliaged plants, will also flourish under such conditions, and many species of Orchids will find a congenial home therein. Such a house may be kept gay from November till June. The best form for a house of this kind is a span-roofed one about 12 ft. in width. This will afford space for a 3 ft. path and a 4½ ft. stage on each side. Ample ventilation should be provided at the top, but a single board to open the length of the house will suffice for the admission of air at the side. If the house is to be employed in summer for the growth of such plants as require a comparatively moist, close atmosphere, such as Ferns, Dracenas, &c., then a flap here and there in the brickwork will be all that is needed. Houses of this description are not only useful, but may be made to assume an ornamental appearance during the winter months. In order to attain this end, a selection of plants should be made which will afford considerable variety of form and colour. In many plant structures, the path on each side is bounded by a brick wall, on which the stage rests; but, in the present instance, I would recommend that it should be supported by light pillars, thus leaving an open space under each stage which will be found useful. The constant moisture and filtered light in such

Niphobolus heteractis.

a place supply just the conditions in which many Ferns delight. If the surface be covered with a sufficient quantity of rough, fibrous peat, in which exist pieces of sandstone, clinkers, and other drainage material, *Selaginella denticulata* and other species of Club Moss, Maiden-hair and other Ferns, may be planted, and will flourish and form a verdant carpet, pleasing to the eye, and in every way preferable to ugly brick walls.

In the way of flowering plants we shall find that double *Primulas* and *Epiphyllums* do remarkably well in the gentle warmth afforded them in such a house. The *Primulas* should occupy the lightest situation, and if placed upon inverted pots so as to slightly raise them above their associates, they will flower freely the whole winter through, and as they combine soft pleasing colours with considerable elegance of foliage, they will fully deserve the prominent positions thus accorded them. *Epiphyllums* may be grown either as pot or basket plants; they are beautiful in every way, but they show themselves off perhaps to the best advantage when well established in baskets and hung up near the roof. Being naturally of a pendulous habit they lend themselves well to basket work and display themselves better than when below the line of vision. *Linum trigynum* and *Pentas carnea* are both free-flowering subjects and easily managed. The latter is too seldom seen in cultivation; it is of very easy culture, floriferous, and the bloom is of a soft and delicate hue. Bulbs of all kinds, *Cinerarias*, *Deutzias*, *Spiræas*, &c., will succeed extremely well in an intermediate house, and will develop their flowers in a much more perfect manner than when subjected to the more hurrying influence of a strong or forcing heat.

In selecting plants which are remarkable only for beauty of foliage we must choose those which possess distinct and characteristic features. Amongst Palms we find types possessing grace and elegance, whilst in the large and varied family of *Dracænas* may be found examples of massive, sturdy development, the effect of which is enhanced by a free and graceful outline. To the merits of the Fern tribe it is scarcely necessary to advert. They increase every year in form, and no plant structure, in which a miscellaneous collection is grown, can be considered complete without them. Had we nothing but these three families upon which to rely we should have no difficulty in producing a good effect. Well grown specimens in 6-in. pots of *Areca lutescens* and *aurea*, *Seaforthia elegans* and *robusta*, *Chamerops excelsa*, *Phoenix dactylifera*, *Livistona borbonica*, and *Corypha australis*, look well if placed here and there at intervals so that each plant may be distinctly seen. *Dracenas*, *Aspidistras*, and the more robust-growing Ferns, such as the *Alsophilas* and *Dicksonias*, should also occupy prominent positions. Around and amongst them will be arranged the dwarfier forms of Ferns, flowering and other plants, so that the whole space may be fairly covered without any undue crowding. Additional interest may also be given to such a house by the introduction of such kinds of Orchids as will thrive in the temperature maintained in it. If there be a back wall, it may be draped with *Ficus repens*, and *Tropæolums* of the winter-flowering section may be trained up the rafters. Nothing gives a better finish to a plant house than a few hanging baskets well established with suitable subjects, such as *Goniophlebium subauriculatum*, *Davallias*, *Adiantum Capillus-Veneris*, *Platycoerium albicorne*, *Columnarias*, *Russelia juncea*, &c., whilst a few Orchids, either on blocks or in baskets, will still further increase the effect. Plants of a drooping character, such as *Isolepis gracilis* and the variegated *Panicum*, may be so placed as to partially drape and break the rigid edges of the stages, so that by a skilful disposition of the plants there need be but little of the interior of the structure visible.

In such a house as that just described one would not naturally attempt the culture of such plants as *Ixoras*, *Crotons*, &c., but as I have endeavoured to show there are plenty of beautiful subjects that will enable us to dispense with their presence.

J. CORNHILL.

Bifect.

Begonias and similar plants. The best method of cultivating this *Justicia* is to insert cuttings of it in March, and grow them in a cold frame during the summer months. Early in autumn transfer them to an intermediate house. A mixture of loam, peat-mould, and sand, with a little rotten manure, suits it well, and 5-in. pots will be found the most convenient for decoration purposes.—A. HOSSACK, Ragley, Alcester.

HEATING AND VENTILATING IN COLD WEATHER.

I place these two in juxtaposition for the obvious reason that the one forces heat into glass houses and the other lets it out. This statement, however, by no means includes all the uses of either heating or ventilation, but it places the two main purposes in direct contrast and striking opposition, and this view of the matter needs to be constantly enforced. Much of the waste of excessive heating, most of the evils of reckless ventilation, originate from the lack of a proper adjustment between the two. Economy, as well as the well-being of all plants under glass, pleads that no more heat should be given than is necessary; not only is all excess of heat superfluous, but it is also injurious. It weakens, enfeebles, and discolours plants in flower, and invites the inroads of insects and the attack of disease. All this is bad enough, but still worse results mostly follow excess of heat. Hardly has the temperature been found to be too high, than much or little of the external air is suddenly admitted to lower it. This seems such a simple and natural operation that it is performed almost mechanically, and very much as a matter of course, yet few things are more dangerous and injurious to plants than this sudden lowering of artificial temperature in cold weather by a rush of external air. The plants are thus subjected to a severe draught, and catch cold as suddenly and severely, though they bear it more silently than we do ourselves. Unfortunately, too, they do not show the injury at once. Thousands of plants are crippled and finally killed by chills, though the cause is never suspected, and no injury may be manifest till months afterwards. It cannot, I think, be too often repeated that warm air is moist and that cold air is dry. No sooner does the hot air rush out through the open ventilators and the cold air rush in than the latter fastens on every flower, leaf, and stem, and remains sufficiently long on each and all until it has quenched its thirst. The quantity of cold air can thus drink up out of those delicate surfaces and substances may be measured almost to a nicety by the difference between the internal and external temperature. The greater the disparity the more the air drinks and *vice versa*. Hence the superlative importance of so nicely adjusting artificial heat to the internal wants of hothouses as to ventilate but little, if at all, in cold weather. But then there are those sudden gleams of sunshine that often violently disturb the temperature of our glasshouses even in winter. These matter little. With the careful regulation of fire-heat on rational principles, with an eye to the probabilities of sunshine, no injurious amount of heat is likely to come from the latter; in fact, a rise of 10° or even 15° of heat from solar influences is not injurious, but often the contrary, and those who think otherwise may safely try such advances of temperature in their own practice. They will assuredly find that such, or even greater, advances of temperature by solar heat will at least do far less injury to tender vegetation than the sweeping down the temperature by an inrush of cold air and an outrush of hot air. Much has also been written on the absolute necessity of a change of air in glass houses. Heterodox as it may appear to many, I have no hesitation in asserting that such necessity has not been proved, and, had it been so, it may be contended with equal force and truth that such changes are always being effected without our aid and in spite of our hindrances; for, whatever complaints may have been made against the want of sufficient ventilation in some of our modern glass houses in summer, no cultivator has yet found fault that mechanical ingenuity, close-fitting workmanship, or large panes, has made his glass house too close for winter or early spring. The chinks in the roof so much desiderated—for the colouring of Grapes—will not be held to be equally useful for the swelling of winter berries, or the forcing of flowers or Grapes at Christmas. As new plants need more heat, give less outside air in winter. Indeed, conservatories, greenhouses, and, assuredly, plant stoves and orchid houses, may be almost hermetically sealed from November to February, not only with impunity, but with manifest advantage at all times and seasons when the thermometer falls below 45°. Such practice would cut down the coal bill by nearly a half in many gardens, while it would also preserve the plants in more robust health, and help to clothe them with greater beauty.

D. T. FISHER.

Alsophila pigmea.—This is a charming miniature species of Tree Fern, and a most beautiful subject for table decoration, although

Justicia speciosa a good Room Plant.—At this season of the year I find this to be a most useful plant for the decoration of drawing rooms. The flowers, individually, do not last long, but as they open successively in profusion, even in rooms, they are invaluable. Their colour (purplish-pink) associates well with that of

I fear that it is at present too rare to be much employed for that purpose. The stem is very slender, and the fronds of a lustrous green are disposed in the most graceful manner. It is altogether a gem amongst Ferns, and one which should find a place in the most select collection. Never attaining great dimensions, it is admirably suited to small houses, and, when placed in a prominent position, cannot fail to command admiration.—J. CORNHILL, *Byfleet*.

HEATING SMALL PLANT HOUSES.

ADVERTING to the remarks of "A. D." respecting this subject, allow me to say that I have a heating apparatus which I have found most convenient and economical. It consists of two 2-in. iron pipes (a flow and return) running along under the front stage of the greenhouse, and connected by small pipes with a gas boiler which is enclosed in a brick chamber in one corner of the house. A small iron door in the outside wall of the house communicates with this chamber, and a zinc pipe carries the fumes from the chamber to the outer air. The burner used for the gas is an atmospheric burner with a ring of jets, such as is used for cooking, and this is sufficient to maintain in my little house (8 ft. by 6 ft.) a temperature of from 15° to 20° above that of the air outside, and with a greater length of pipe it would efficiently heat a house double the size. I have at times used this apparatus for a fortnight at a time without further attention than keeping the pipes filled with water, and its management is so simple that a lady could use it without soiling her fingers. In laying on the gas care should be taken that all pipes out of doors should be of iron and of sufficient bore to obviate the risk of any water that might accumulate in them getting frozen in hard weather, and a syphon should be provided in the lowest point of the gas pipe to allow of such water being removed.

W. J. T.

Brixton.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Solanums Best in Poor Soil.—Some of these most useful plants for winter decoration, which were grown in rich soil last year, made plenty of wood but did not form half so many berries as those growing in very poor soil. In future I shall therefore give preference to soil poor rather than rich.—CAMBERLAND.

Primula sinensis fimbriata.—Primulas are often raised in too high a temperature. Those plants are best which are brought on steadily from the time the seeds are sown till the plants bloom. There ought not to be any necessity to pinch off premature flowers, as such flowers plainly denote misdirected force, and are out of place. A warm greenhouse, or a slightly heated frame of about the usual greenhouse temperature, say about 50° during the night, will be quite warm enough to start the seeds. The young plants should be pricked off, when large enough to handle, 2 in. apart, and placed in the same temperature again, keeping them shaded for a few days, but moving them to a light position near the glass as soon as the roots have fairly grasped the soil and feel at home in it. When fit to transfer to single pots, a frame should be arranged for them in some open situation, with 4 in. of coal ashes in the bottom to set the pots on, and to keep out worms. The frame should be kept close for a few days, and then have ventilation, increasing in amount as the season advances. The plants should stand thinly, so that their crowns or whorls of foliage may have room for development, and be potted on as they require it, giving the last shift to the early-blooming plants about the end of August, and the late ones in September. It is best not to over-pot, as large plants can be grown in 6 in. pots. A mixture of loam and peat or leaf-mould suits them well, with a sprinkling of sand or charcoal dust to insure porosity. A larger proportion of loam may be used in the last shift than in previous ones, but it must be fibry, and simply broken up, not sifted. The watering must be carefully done, especially for a few days after being transferred to fresh pots. The plants may be left in the cold frame till October, when they should be taken to a greenhouse; and the flowers will be finer if a little fire-heat be used to keep the air in circulation, and to permit of the free admission of fresh air when not absolutely freezing or very windy. In a low temperature in winter damp is apt to lodge on them, which induces decay about the crown, often damaging the flower-spikes and foliage. Late-sown plants are best to save seeds from, and the best flowers only should be selected. A light position in a cool, dry house will be best for seed purposes, and a camel's-hair pencil should be used daily when the pollen is dry. The best strains are, as a rule, the least prolific seed producers.—E. HODGKIN.

NOTES FROM KEW.

Hardy Plants.—Owing to the late severe weather there is a general dearth amongst hardy flowers compared with the corresponding week last year. The only plant attractive here is the charming little *Milla Leichtlini*, which is both new and rare. Its flowers are just peeping above the soil from a rosette of narrow leaves. They are about the size of those of the better known one-flowered *Milla* (*M. uniflora*), but white, with faint, radiating, green streaks; and they are, moreover, delightfully fragrant. It is found at high elevations on the Andes. A few kinds of *Crocuses* are yet in flower, notably the deep orange-coloured *C. vitellinus*, a native of Syria, which is pre-eminently the best of all the winter-flowering kinds. It has been continuously in flower for several weeks, even striving to push its way through a covering of snow. *C. syriacus* much resembles it, but differs in having the outside of the flowers striped more or less distinctly with black. Though known as long ago as the days of Dean Herbert, these are as yet very rare in gardens. Another fine kind is a form of *C. Boryi*, named *lavigatus*, which differs from the type in the flower being suffused with purple, and being feathered on the outside with black. It is a native of South East Europe. *C. Schimperii* (syn. *C. cancellatus*) is pretty, having long, white flowers with a basal zone of orange colour. *C. longiflorus* (syn. *C. odoratus*) is a better known kind, but none the less desirable as it continues to throw up its mauve-coloured blossoms for a long time during late autumn and winter. Turning to the Christmas Roses we see here that ere long a recently acquired, and, we should say, a complete collection will be a source of much interest to those who care for this class of plants. The only kinds at present in flower are *H. altifolius*, and a fine example of the ordinary kind, and also the not showy but handsome-leaved *H. foetidus*.

Greenhouse Plants.—The conservatory is now beginning to assume a somewhat gayer appearance by the introduction of the various kinds of spring, bulbous, and other forced plants. Two showy *Acanthads* are made free use of, and are well adapted for the purpose, viz., the old *Justicia speciosa*, a profuse flowering kind, with violet-coloured blossoms, and *Sericographis Giesbreghtiana*, a plant with peculiarly-mottled stems terminated by a one-sided raceme of long, tubular, scarlet blossoms. *Senecio Giesbreghtiana*, is a handsome Groundsel with large, coarsely-toothed leaves, and dense clusters of bright orange flower heads. In one of the *Camellia* beds is a finely-flowered specimen of the lovely Nepalese shrub, *Luculia gratissima*. It would be difficult to conceive a more desirable winter-flowering plant than this when seen covered with large clusters of delicate pink blossoms, which yield a delicious perfume. It is, moreover, very easy to manage in a cool, airy house, though difficult to propagate. Another old favourite is *Leschenaultia formosa* from New Holland. *Cestrum aurantiacum*, an old introduction from Guatemala, deserves more extended cultivation than it receives, as it is one of the most useful greenhouse plants we have, and is specially adapted for training to rafters or pillars. It is an evergreen with long terminal racemes of rich orange blossoms, tubular, and about 1 in. long, flowering from October till February. In the central bed is a remarkable Australian Protea (*Banksia collina*), bearing numerous dense cones of curious, brownish-coloured flowers. The winter garden, too, will soon be enlivened by an almost endless variety of winter-flowering *Acacias*, and a host of other Australian plants. The only kind at present which attracts attention is the old *A. platyptera* from Swan River, with its curious flat stems, which do the service of leaves. *Coprosma lucida*, a large evergreen shrub from New Zealand, now forms a very interesting object, the stems and branches being thickly covered with small reddish-orange-coloured berries.

Stove Plants.—In the T range the first plant which claims attention is *Erythrotis Beddomei*, which makes a pretty basket plant with slender stems covered with silky brown hairs, and small flatly-arranged leaves, hairy and green above, dark purple beneath. The flowers are borne at the tips in clusters, the petals being pale violet, the very hairy stamens blue tipped with yellow anthers. It belongs to the Spiderwort family, and is found on dry, bare rocks, at 3,000 to 4,000 ft. elevation, on the Myhendra Mountains of South Travancor. *Jatropha podagrica*, a native of New Granada, is of quaint aspect, with large gouty stems and crooked leafless branches terminated by a cluster of small scarlet blossoms with golden stamens. *Apheleandra nitens*, from Guayaquil, and *aurantiacea*, from Mexico, must be placed as front rank species of a showy genus. Both are strikingly similar in form and colour of the flowers, which are of a dazzling scarlet borne on erect spikes, but the former differs by its shining, bronzy leaves, whilst those of the latter are variegated with silvery markings. Behind these a comparatively small specimen of that most graceful of all Palms, *Cocos Weddelliana*, is flowering freely; though rather inconspicuous, and not of uncommon occurrence, we take the opportunity to advocate its claim to more ex-

tended cultivation as a decorative plant of the highest order, more especially for indoor table adornment, as it is of easy culture, and retains its small state for some years. *Rondeletia Backhouseana* is a large winter-flowering shrub of rather coarse habit, bearing large, terminal clusters of tubular, bluish-coloured blossoms. It is a native of Tropical America. In the adjoining compartment Begonias are abundant, and, as most people are always on the outlook for desirable winter-flowering plants, the following selection may be relied on as answering the purpose satisfactorily. The well-known *B. nitida*, with bluish-coloured flowers, and a kind named here as a near ally to it, are robust and very free-flowering; *B. falcifolia* has flowers of darker hue and spotted leaves; *B. semperflorens*, odorata, and *suaveolens*, pure white; *B. incarnata*, and *Lapeyrolae* with pinkish-coloured blossoms. *Crotopogon Luyanus* is not nearly so well known as it deserves, though of staggling habit with long, pointed, finely-toothed leaves, the upper third of the stems produces in continuous succession numbers of its long, curved, tubular blossoms of a delicate rose colour very useful for cutting purposes. It is also very interesting as being one of the few generic hybrids in cultivation, it being a cross between *Siphocampylus betuleifolius* and *Crotopogon fastuosus*. It was raised at Marseilles about twenty years ago. *Linum trigynum*, a native of the East Indies, though it has been in gardens for well-nigh a century, is also too little known, for few plants can surpass it when covered with its large silver-stemmed golden blossoms, as we see it here. The white variety of *Poinsettia* is used here with good effect, the cream-coloured flower-leaves associating admirably, and toning down as it were its brilliant scarlet congeners. In the Cactus house several kinds of Aloe are flowering, viz., *A. pictilatis*, with curiously-arranged leaves in a fan-like manner; *A. scottiana* arborescens and *pluridens*, all very similar in form and colour of flowers, which is of a reddish-orange, and very handsome. Overhead, trained to a rafter, is a climbing kind, *A. ciliaris*, with flowers resembling the others, and tipped with green; they are all natives of the Cape. *Agave schidigera* is a very remarkable plant, with the edges of its sword-like leaves beset with short, curly, silvery threads. Its flower spikes rise over 5 ft., on which are thickly arranged, greenish-coloured blossoms, with six long, dull purple stamens. One or two succulent plants illustrative of the arid region of Mexico are flowering freely, viz., *Cotyledon fulgens* and *retusa*, both with very glaucous stems and oblong leaves and terminal clusters of orange-scarlet blossoms of thick texture and very ornamental. W.

NOTES OF THE WEEK

Seented-leaved Pelargoniums in Hanging Baskets.—These form, at the present time, a striking feature in the Crystal Palace at Sydenham. The plants are growing in large wire baskets suspended from the roof, and are allowed to droop naturally and gracefully all round the baskets. Being kept free from dead leaves, they thrive luxuriantly, and, on account of their elegant, deeply-cut foliage and sweet scent, they rank among the best of basket plants for winter decoration.

Ornithogelum thyrsoides.—This is now producing, in Mr. Ware's nursery at Tottenham, fine spikes of pure white blossoms, which at this time of the year are valuable for many purposes. It thrives well in pots in any moderately warm house, and would make a good plant for forcing into bloom at Christmas, a time when good white flowers are valuable.

Genetilis Hookeri.—In the large collection of hard-wooded plants in the Victoria Nursery, Holloway, none are more attractive at the present time than large specimens of this *Genetilis*. It flowers earlier than *G. tulipifera*, and is more showy and easier to cultivate. It lasts in flower for several months in succession, and its bright red, bell-shaped blossoms are shown off to good advantage among white Cyclamens, white-flowered Jasmines, and similar plants used at this season of the year for conservatory decoration.

Moss-clad Tree Ferns.—Bare stumps of Tree Ferns, in Mr. Day's garden at Tottenham, are effectively clothed with *Selaginella denticulata*. It is planted in the soil round the bases of the Ferns, and encouraged to grow round them, which it does rapidly, provided the stems of the Ferns are kept constantly moist.

Romulea Macowani.—My pits, in which was a collection of the rarer kinds of bulbs, had been snowed up for a fortnight, so that I could neither admit light nor air; but after the severe frost a thaw set in, rapidly melting the snow and ice, and on opening the frames I was agreeably surprised to perceive large flower buds on *Romulea Macowani*. They are brownish-crimson when closed, resembling, in that respect, those of the brown-striped yellow Crocuses. On the first sunny day they opened, and showed a bright yellow star-shaped

flower as large as a half-crown piece, the cup being a little darker in colour than the rest of the flower. I am led to suppose that the plant will be quite hardy, and although, when without protection, it may not flower quite so early, yet it must be classed amongst our earliest spring-flowering plants, and it is one which will be greatly appreciated. Iris *Histrio*, close by, will not be in flower for from fourteen days to three weeks yet.—MAX LEICHTLIN, *Baden Baden*.

Barkeria Skinneri.—This is becoming a scarce plant even in nurseries, a circumstance to be regretted, for when well grown and flowered, as we find it in Mr. Day's garden at Tottenham, it is one of the most attractive of winter-blooming Orchids. Its flowers, being of a rich violet or purple colour, form a striking contrast to the pure waxy blossoms of *Odontoglossum Alexandrae*, of which there is now a good display in the garden in question.

Freesia refracta alba.—This is an excellent plant for the decoration of conservatories at this dull season of the year, and it is also well worth cultivating for the sake of its flowers in a cut state, for, being white and sweetly scented, they are useful in bouquets or other floral decorations. It is a plant that is easily cultivated, and one which will thrive in a cool frame or greenhouse. It may now be seen in good condition in Mr. Ware's nursery at Tottenham, some plants of it bearing numerous graceful spikes, each of which is furnished with from seven to eight flowers and buds. The flowers also possess the desirable property of lasting for a long time in perfection after being cut.

Orchids at Holloway.—At this season of the year when flowers are in most demand but comparatively scarce, a good display of Orchids, such as may be found in Mr. Williams' nursery at Holloway, is doubly valuable. Among other attractive kinds are banks of *Calanthes*, *Oncidium biflorum*, furnished with gracefully arching spikes of golden-yellow, orange-tinted blossoms, fine varieties of *Lycaste Skinneri*, the brilliant *Sophronitis grandiflora*, *Odontoglossum Cerrantesi majus*, the graceful sweet-scented *Oncidium cheirophyllum*, and the chocolate-flowered *O. nevadense*. To these may be added well-flowered examples of *Angraecum sesquipedale*, and a variety of *Lady's-slippers*; these being associated with Ferns, Palms, &c., a fine effect is produced.

Masdevallia Tovarensis.—This is one of the best of the *Masdevallias* for winter blooming. Plants of it, even in a small state, yield large quantities of pure white blossoms which are valuable in a cut state for bouquets. We lately saw numbers of well-grown plants of it in Mr. Day's garden at Tottenham, where, associated with other Orchids of an attractive character, they were set off to advantage. This *Masdevallia* may be grown in pots, but it is much more effective when cultivated in shallow pans.

Habrothamnus elegans.—This is grown effectively in pots at Frogmore for decorative purposes. Plants of it are struck from cuttings in spring, potted into small pots, and kept indoors till the weather becomes mild, when they are planted out in the open ground for the summer. Their shoots are stopped several times during the growing season, and in autumn the plants are lifted and potted in 6-in. pots, and placed in the greenhouse, where they become bushy and handsome, and bear a truss of blossom at the end of every shoot, causing the latter to arch in a graceful manner. Such plants are now coming into flower at Frogmore, where they are much prized for placing in vases and in rooms, or in the conservatory.

Salvias at Frogmore.—These are largely grown here for supplying cut blooms in winter, and also for furnishing specimens for antique vases in Windsor Castle, a purpose for which few other plants are so well adapted. They are struck from cuttings in spring, and planted out in good soil out-of-doors in June. In September they are lifted and potted, and removed indoors as soon as the severity of the weather necessitates such an operation. They are placed in empty fruit houses, or similar situations, as near the glass as is convenient, in order to keep them dwarf, and to prevent the leaves from falling off. The first to bloom is *S. splendens*; this is followed early in the new year by *S. Heeri*, and when this is nearly over in March, *S. gessneriflora* comes into bloom, and thus a succession of useful flowering plants is maintained from November till April.

Variegated Pine Apples.—These are used for room decoration at Windsor Castle. They are raised from suckers grown in 6-in. or 8-in. pots in bottom-heat, until they are large enough for use, when they are placed on inverted pots near the glass in a slightly cooler temperature. Any one possessing a Pine stove or Cucumber pit, or any place in which a bottom-heat of from 70° to 75° can be maintained, with a moist atmosphere, may grow variegated Pines in perfection, and, when well grown, no plants are more distinct in character, or more effective. They last well in rooms, and, their leaves being smooth, they can easily be cleared of dust, which is unavoidable in such positions.

THE FRUIT GARDEN.

THE REFRIGERATING FRUIT BOX.

A LIGHT, portable refrigerator, for shipping fruit and vegetables by southern growers to northern markets, has recently been invented by Mr. H. A. Duc, of South Carolina. It consists of a box of light wood, lined within with galvanised iron, a space being left between the box and lining of 1 in. or more, which is filled with charcoal or other non-conducting material. The box is provided with one or more shallow, movable ice boxes, made of galvanised iron, provided with handles, and an opening which is closed by a screw cap. The boxes are filled with broken ice, and closed so securely that no water from the melted ice can escape and injure the fruit. These ice boxes are of the same height as the fruit baskets or cups, and may be substituted for a tier of these, allowing one or more to be used, according to the requirements of the season, one, at the top, being sufficient in moderately warm weather, and as the season grows hotter one of the lower tiers of fruit may be replaced by a box. Fruit received in New York from southern points can, by means of these refrigerators, be safely re-shipped to Boston or elsewhere; the boxes being replenished with ice, it is ready for another journey. Before giving an opinion of this invention we visited several of the principal commission dealers in New York, and found that the representations of the patentee were fully confirmed by those who had tested it, two firms, dealing largely in Strawberries, stating that fruit received in this refrigerator brought, on the average, 10 cents more a quart than that shipped in the ordinary manner. An instance was cited of a shipment made from Charleston so late as May 10, in which the Strawberries received in Mr. Duc's refrigerator averaged 23 cents per quart, while those carried in the steamers' ice boxes brought but 12 cents, the difference being due solely to the superior condition of the former. The cases are made square, or longer than they are wide. The one here shown is 28 in. square by 19 in. high, and is provided with strong handles which shut down flush with the sides; the cover, shown at the rear, is double, and filled in the same as the sides; this is fastened down by screws with square heads, which are countersunk. The ice boxes, one of which is seen at the right hand, are 4 in. high, of a size to fit the interior of the case; the opening to admit the ice is about 3 in. across; the cap is screwed tight by means of an iron rod, bent as seen in the engraving; its ends fit into two holes in the cap; when not in use this handle is removed and laid upon the ice box. A case holding 72 quarts, when filled and ready for shipment, weighs about 250 lb. Though Mr. Duc has taken out a patent for the invention, he liberally allows us to say that he will permit any fruit grower to make the box for his own use without exacting a royalty for his patent.—*"American Agriculturist."*

A Refrigerating Fruit Box.

the way with a shovel, so as always to retain plenty of room in the trench. There is nothing shows the skilled workman more than little matters of this kind, keeping the trench well open when digging up or removing a large sized tree. Unless this is done, there is no chance of getting properly under the tree, and saving intact most of the roots. Indeed, unless the roots can be saved free from blemish, it would be hardly worth while taking pains to save long roots at all; but when plenty of good roots can be secured, and the transplanting is done in autumn, very few of the trees so moved will feel any the worse for it; and, if their systems were the least bit out of order, they will probably be all the better for the change. I have said large wall trees can be moved with much greater ease and certainty of doing well than untrained trees. One of the main causes of this is, they can be so easily secured from wind-waving after planting by attachment to the wall. I have no doubt in my own mind that the principal cause why large-headed trees fail in transplanting is the difficulty of securing them in their new positions so that the roots may have time to get a firm grasp of the new soil. Where the trees on the walls are all doing well, of course most people would say, leave well alone; but there are times when the removal of a large tree would in various ways be a manifest advantage. Perhaps the trees on a particular wall may have been originally too thickly planted; and, in order to give space for individual development, a re-arrangement must take place, involving the removal of some, if not all of them. Or a tree occupying a prominent position may become weakly, or be worn out, and trees are like men, some wear out faster and earlier than others, and their removal becomes necessary; and if by a rearrangement of the others the blanks can be profitably filled, it is always well to do so, although of course the labour involved will be very much more than just merely planting a young tree would be. But a man who takes a pride in keeping his walls well filled up, unless his hands are needlessly tied, will generally so arrange his work that the labour and time

are forthcoming. It often happens that a tree showing symptoms of weakness, the first signs of which are easily detected by the watchful eye, will on removal to a fresh site be restored to health and fruitfulness. I know, in my young days, there was never an autumn passed without the walls being looked over and the trees put right. From my experience then and since, I know the system to be a good one if rightly carried out. But the earlier it is done the better; indeed, it would be imprudent to delay it much after Christmas. The roots should be carefully arranged, first cutting out all damaged or mutilated portions, making the cut as nearly straight across as possible. When a long cut is made, the descending sap will not be arrested till it reaches the lowest extremity of the wounded surface, and the callus will be formed there, and roots protrude, long before the upper part is healed. But if the cut be made straight across, the wound will heal at once, and be covered with a new growth, and tufts of new roots will soon be emitted. I have generally found a sharp pair of pruning scissors answer well for this work, as they cut straight across, and so far as my experience goes, do not seriously injure the bark. It is a common practice in tree planting, to lay the roots all out straight in one layer; but with large trees, that have been, perhaps, once or twice lifted previously, and where the roots are numerous, they will be far better if distributed more equally in the soil. The lower tier of roots should be spread out first, and covered with good mellow soil, and then another layer regularly disposed, and so on till the work is completed. Even where the soil is suitable and in good order, it will be very beneficial to add a few barrowfuls of fresh, mellow, turfy

TRANSPLANTING LARGE-SIZED WALL TREES

WALL trees of large size are easy to move compared with other trees not so circumstanced. It is an easy matter to untie or unnaill a tree from the wall; to carefully secure its branches with strong, soft matting, so that they cannot chafe or injure each other by friction during the process of removal; and then, when the branches are made safe, to commence far enough away from the trunk, 6 ft. or 8 ft., according to the size of the tree. Dig a deep trench, so as to get beneath the roots, and then gradually work upwards to the trunk of the tree with the fork, picking out the soil carefully, and working it back out of

soil round the roots, to give them a quick start. The trees should only be loosely secured to the wall for the present, as time must be allowed for settlement before they are finally trained. I don't think it a good plan to plant too near the wall; the base should be allowed plenty of room to increase in size. It is common enough to see trees almost bursting from the wall by the swelling of the trunk at the base, through being planted too near the wall. Before planting, the bottom of the hole should be made quite firm, and have a very slight fall to the front; but it need not be much, as the roots are always ready enough to acquire a downward tendency. By covering the roots with good mellow soil, no harm will be done by applying a little pressure with the feet before the levelling is finished, and the surface should be well mulched with half-rotten manure. It is a good plan to have a few young trees coming on, to fill up any vacancy that may occur at any time. If there should be no vacant places on any of the walls, where a young tree or shrub may be progressing till they are required, they will do very well trained to stakes in any vacant spot in the garden. It is far better to do this than to have to run to a nursery and take the chance with others, when trees are wanted. By buying a few "maidens" occasionally, plenty of good trees might always be ready when wanted.

E. HOBDAY.

OUR SUPPLY OF APPLES AND PEARS.

It is the opinion of some, that the production of Apples and Pears in the United Kingdom has ceased to be a matter of much importance, now that the Americans can pour these fruits into our markets and shops so speedily and in such large quantities. Fruit is now sent on to us some seven or eight thousand miles across the Rocky Mountains, and three thousand miles by sea, in good quality and condition, in a comparatively few days; and that certainly may be ranked among the facts that are stranger than ever fiction anticipated. Our French neighbours also cultivate these fruits to make up the deficiency of our home produce. It is well that these sources can be looked to for a supply of wholesome fruits, which in the case of Apples can be purchased at a rate that enables the frugal peasant and artisan to enjoy their tarts and puddings. The question, however arises, Ought we to be so dependent on foreign sources for a full supply of these fruits? This, like every other question, has doubtless two sides to be looked at; but our object at present is not to discuss it in the abstract. Our conviction is, however, that our home production might be much more satisfactory than it at present is, even in spite of many adverse circumstances. Some have assumed and tried to prove that the climate of this country has changed so much for the worse that Apple crops are not now what they formerly were. This we believe to be an assumption that has no foundation either in statistics or anything else, and is repudiated by the recognised fact that drainage and high cultivation have had rather a beneficial influence on our climate. Be that as it may, we have no more doubt that many districts in the United Kingdom could be made much more productive of these fruits without entrenching on lands remunerative in other ways, than we have of our own existence. The question may be asked, By what means? Of course, to begin with, by planting more trees. This may be met with the assertion that there never were so many trees raised and planted as there are in these times—a statement that may be true. But is it not near the truth that much of the planting might as well be left undone, and many of the trees might as well be burned, for any share they have in increasing the supply of fruit. We must of course endeavour to give reasons for this last assumption, as it may be termed. In the first place, we have never yet had to do with Apple and Pear trees in any district, without having the fact, that the supply of fruits in five years out of six has been borne by a comparatively few sorts, very forcibly illustrated. This observation is not by any means singular to any cultivator; and we believe if it were more carefully considered, and only those productive varieties planted all but exclusively, the bulk of fruit produced in a great number of localities would be increased fiftyfold. As an instance of this fact, we now practice it in one of the very worst spots that could be chosen for hardy-fruit culture—i.e., a low damp valley close to a river, with a heavy soil on a clayey subsoil, and an average rainfall of fifty inches, and where spring frosts are very prevalent. Yet only twice in ten years has the yield of Apples not been sufficient for the supply of one of the largest establishments for three months, and from comparatively few trees—under what we consider adverse circumstances—in the vegetable garden alone. We are now so well acquainted with the few varieties and trees that are productive, that we could venture to point out those that are likely to be fruitful the following season; and the varieties could be more than counted on our fingers. If every tree in

gardens were of these varieties, there would be supply enough for eight or nine months of the year. The blossom produced by other varieties is most encouraging, but their crop is almost always *nil*. It is therefore not reasonable to expect, that if those varieties that bear thus were largely planted in this and similar districts, the produce would be much increased with the self-made labour in culture? The same rule we have noticed to apply more or less to other districts. The indiscriminate planting of kinds not suited to localities has been found out by market-growers to be a great mistake, and they are now acting on the principle of selection.

Another practice, and, considering its results, one that has been adhered to with an amount of tenacity that is remarkable, is that of planting Apples and Pears by the sides of walks, in what are termed cross-borders, in kitchen-gardens, and even dotting them about in vegetable quarters—the spaces of ground between trees in these positions being frequently occupied with biennial and other flowering plants, and sometimes with Strawberries and vegetable crops. These borders, if devoted to flowers, are rarely properly manured, and are deeply worked with a spade annually among the plants, and close up to, if not over, the roots of the trees. If devoted to vegetables, they are, on the other hand, heavily manured and deeply dug. To escape mutilation, the roots of the trees, with a sort of self-preserving instinct, proceed to find peace and comfort in a too often unsuitable and canker-breeding subsoil. In the one case the roots are starved, and in the other too grossly fed; and the respective results are stunted growth and poverty-stricken produce in the one case, and in the other too gross a growth of unfruitful wood, to be annually and ruthlessly cut away with the pruning-knife. Of these two evils it would be difficult to say which is the worst or most unreasonable. Trees in such positions as the one named must of necessity be kept in very restricted limits as to size, or injury to the plants among which they stand would be greater than it really is; and even with all the restriction practised, the one crop is most injurious to the other. To make matters bearable, the pinching and pruning are carried to an injurious excess every year, leaving as many knife-wounds as make it a wonder that decrepitude, canker, and decay are not still more frequent. The pruning of such trees, after the fashion of the present day, is an evil; and it is to be feared that in not a few cases it is resorted to to permit of the other evil of making room for growing every conceivable variety in a given space. Root-pruning every two or three years is perhaps the more reasonable course to pursue; but if trees are to be grown with a vigour capable of bearing a full crop of good fruit, it is a process that can only be carried to a certain extent, and that not sufficient to do away, under the circumstances, with the murderous pruning which leaves trees more conspicuous for their number of knife-wounds than for anything else.

This miniature-tree system, mixed up with other crops, is, generally speaking, not satisfactory. It is injurious to other kitchen-garden crops, and leads to so much cutting and restriction, that it never will admit of a satisfactory supply of fruit, even if the selection of sorts be ever so suited to the locality. In so important a horticultural matter as this, it is strange that we adhere so tenaciously to the mixing of fruits with other crops; and the evil is most flagrant in what are termed the best of gardens; and hence the faithfulness with which it has been copied. For those with only one small piece of ground there is some excuse if they desire a few varieties. But even in their case the trees would do better located by themselves.

There is no serious reason that we know of why there is so much of this mixing up of standard fruit-trees with kitchen-garden produce, instead of putting them by themselves, where they and the ground can be much more specially treated in accordance with their wants. By doing so, many telling advantages are gained for both departments. The evils of digging in heavy dressings of rank manure, and of mutilating the roots of the trees, find no excuse, and can be entirely avoided. Neither need the trees be starved or injured by being improperly fed when they want extra nourishment. No spade or fork should be thrust among the roots of trees to dig in manure. A firm surface, subject to no more tillage than what will keep it clean, having the necessary manure spread on, inducing the roots to keep near it and be fed with the beneficial elements of, instead of coming in contact with, the manure—this way of managing the soil produces a more moderate growth, and altogether that state of health without grossness which is so desirable.

Then the trees, to be worth the name, can have room and liberty to develop without injury to other crops and with benefit to themselves. The pruning is reduced to a minimum sufficient to admit light and air to the various parts of each tree, instead of the stag's-horn style of pruning off almost every inch of wood made annually. The compromise between nature and art mutually working into each other's hands results in the building up of trees that frequently do more to fill fruit-rooms with fine fruit than when they are managed on the other principle which we are contrasting.

Besides, trees in an orchard give an amount of shelter to each other that is an important factor in securing comparative safety from the blighting influence of winds, which do so much damage to the blossom. By observing these few cardinal points more generally—the proper selection of sorts, the orchard system of planting, natural root-culture, and less pruning—much more and better fruit would be produced in a great many districts. The culture would be simplified and the labour lessened. On the other hand, the vegetable-garden would also profit by such an arrangement to no inconsiderable extent. This, coupled with the planting of many a nook of ground now not much better than waste, would very much increase our home supplies, as compared to what is grown in gardens, making us more independent of foreign supplies of at least the commonest, though not the least useful, of these fruits, which it is desirable to make still more plentiful, cheap, and popular among our toiling millions.—“The Gardener.”

THE VARIETIES OF DAMSONS.

The Damson is one of the most popular and widely cultivated of English fruits. Many hundreds of acres of land in certain districts of the country are devoted to its cultivation, but it is in our cottage homes, and in labourer's gardens, that the Damson is most prized, the crop of this fruit being looked upon as security for the rent. The Damson is a true English fruit. It is not found in cultivation on the Continent, or elsewhere, excepting America, where it has probably been introduced from this country. Of Damsons there are several varieties, all originating from the wild Plum, *Prunus institia*.

English Damson.—This is the most common variety, and is sometimes called the Round Damson, Common Damson, Black Damson, &c. The fruits are small, roundish-ovate; the skin deep purple, or nearly black, with a fine bloom. Flesh greenish-yellow, acid, almost as austere as a Sloe until quite ripe. It ripens early, and is a great cropper.

Shropshire Damson, or Long Damson, Prune Damson, &c.—The fruits of this are much larger and longer than those of the common English Damson. It is of a long ovate shape, tapering mostly to the stalk; the skin thick; flesh thick, adhering somewhat to the stone. This is a variety of excellent quality, and the best for making preserves, but it is not such a prolific bearer as the common.

American Damson.—With this variety we have not much personal acquaintance, having only fruited it one season. The fruits are large and round, the skin dark purple, and slightly spotted with brown. Flesh greenish-yellow, adhering to the stone, juicy, melting, and sweetly flavoured. Mr. Scott, in his “Orchardist,” says it is synonymous with Frost Gage and Frost Plum, and “is a Plum in much repute in New York market.” It is rather a shy bearer.

Crittenden's Prolific and Rochester Damsons are varieties of great repute in Kent, being of a large size, and very prolific.—“Florist.”

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Outside Vine Planting v. Inside.—I have two late Vineries chiefly planted with Alicante, Lady Downes, and Trebbiano. In one of them the roots are outside, while those of the other are inside. In the former I observe that the Alicantes keep plumper than they do on the Vines planted inside; they are just now (Jan. 4) plump and good, while in the latter case they are shrivelling. I have this day tasted both, and I find the shrivelled ones the best as regards flavour. I shall bottle some of each and see which does best.—R. GILBERT.

Late Grapes.—It is well that all Grapes should now be removed from the Vines if possible, as reaction will soon take place should the weather become mild, and, if pruning be delayed, bleeding will be the result. Lady Downes should be cut first and put in the Grape room, and if that structure be too small to accommodate Black Alicantes, Muscats, &c., these may be left on the Vines for present use.—S.

King of the Pippins Apple.—This is the best Apple which we possess; it never fails to produce a crop. In the very worst of seasons it bears moderately well, and in good seasons abundantly. It is handsome in shape, good in colour, first-rate in flavour, keeps until spring is far advanced, and is equally good for dessert or cooking.—CAMBRIAN.

Concerning Fruit Culture.—The public roads of the late kingdom (now province) of Hanover are nearly all planted with Apple trees. The guardians of the roads are instructed, and take interest in their trees. They guard the fruit till ripe, when the trees are sold singly by public auction and the proprietor has to guard them and take the fruit down without damaging the trees. The money goes to the direction (office) of the public road. These trees give shelter, ornament, and fruits. Do plant trees along railways has not been found practicable, by reason of the telegraph wires, &c. In the kingdom of Wurttemberg (capital, Stuttgart) much has been done in this respect, and proposals have been made to plant the side of the railways, but I do not know with what result.—ALFRED VON SEEFFELD, in “Dietetic Reformer.”

THE FLOWER GARDEN.

STEM ROOTS ON LILIES.

ON Dec. 21 (pp. 560, 561, and 562, Vol. XIV.), four columns were taken up by no fewer than six opponents, all writing in strong terms against my remarks on the subject of stem roots. With respect to their letters they are, on some important points, so inconsistent one with another, that it would be impossible to enter into anything like an intelligible or profitable argument on the subject. With regard, however, to them all, taken collectively, it is fortunate for me that “E. H. W.’s” important and opportune letter appeared on the same day (p. 560), as what he says may be taken as a comprehensive and conclusive reply. He tells us that he has recently visited Japan, and communicates to us some interesting “information about the habitat and growth of *L. auratum* in its native country.” Among other things he says:—“The drying up of the sap in the scales and consequent exhaustion of the bulb’s vital power is the real cause of the ‘mop-like growth of stem roots’ so often seen in late-potted bulbs that have been recently imported.” He says further:—“Stem roots do not strengthen the bulb to any appreciable extent in storing up strength for another season, for on being taken up it is found to have dwindled to a mere nothing.” This is strong confirmation of what I have said over and over again, and to “London Stone” so lately as Dec. 7 (p. 503). “E. H. W.” also says:—“On healthy plants of *Lilium auratum* in their own country stem roots are present only to a moderate degree.” In this country we would say the same of *L. bulbiferum* and the like, without further notice, simply because we do not make the stem roots of that Lily a nuisance by improper cultivation. Again, “E. H. W.” says:—“It will never be found that a really healthy bulb of *L. auratum*, provided with abundant roots of its own, pushes stem roots in any quantity.” Now, the reader cannot but see that this information has been communicated to us by “E. H. W.” without the slightest bias one way or the other. What, then, have my opponents said of me, because I have endeavoured to explain to the readers of THE GARDEN substantiated facts which spoke clearly to the same effect? “F. W. B.” says: “I totally disagree with ‘Dunedin’ with regard to stem roots and their functions.” He says more, but that will require a specific reply. “A. S. O. N.” says: “If stem roots, when they occur in Lilies, do not assist in nourishing the flowers, what do they nourish?” Mr. T. Smith says: “I shall require better argument than any ‘Dunedin’ has yet adduced before I commence to cut off the stem roots. If they are useless, why are they produced?” “E. B.” says: “Will he (‘Dunedin’) have us believe that Nature throws out stem roots, not only without any good purpose to serve, but for no purpose at all?” Mr. Baines says so much, that it must stand over for another occasion. “London Stone” says: “I can only repeat that ‘Dunedin’s’ positive statement of the evil effects of stem roots is mere theory.” Now any reader may easily see that these questions and remarks should not have been addressed to me at all, for the simple reason that “E. H. W.’s” letter shows clearly that they should have been addressed to those who, by their injudicious advice, and misdirected culture, encourage the growth of stem roots to the ruin of the new bulbs. Even the Japanese themselves, from whom we have borrowed erroneous ideas, are now, according to “E. H. W.’s” letter, “thirsting for change and improvement, even greater than in Europe.” It will, therefore, be indeed a great disgrace to us if we, for the sake of preconceived notions, allow them to go before us; for they are, I hear, throwing off the incubus called “The Perennial Theory.” But I am doing injustice to “E. H. W.” himself, by not at once referring my opponents to his letter, and begging them to read it with care and consideration. If they do so, they will see that what they have written in favour of stem roots is very much calculated to injure the culture of the Lily. DUNEDIN.

Wild Plants for the Flower Garden.—Allow me to thank Miss Hope for the information which she has given (p. 539, Vol. XIV.) respecting hardy British and other plants suitable for the flower

garden. Although *Valeriana Phu aurea* cannot be classed as a British plant, it does not seem to be very widely different from the common species known as *V. officinalis*, and as Hooker, in his "British Flora," intimates that there is considerable affinity between them, it is possible that if the latter assumes a golden dress it would be equally valuable. Miss Hope's remarks on *Memm Athamantium* are also just and true. I have met with it on the dry sandy banks about a mile from the coast in a very robust form. For many years I used to cultivate the *Helleborus foetidus*, and thought it bore no inconsiderable resemblance to an Eastern Palm; and moreover, it was a very convenient plant, and withstood winds and severe weather in an exposed vase better than any other plant with which I am acquainted. Could some one impart a silver or golden hue to its foliage it would be a grand plant. There is also a British *Euphorbia* of handsome growth; I am not certain of its specific name, but it is known in some country districts as Jacob's Ladder. The leaves on its stems intersect each other at right angles with mathematical regularity. I have never done more with it than encourage its growth amongst shrubs, but it might be advantageously employed elsewhere. Another class of plants might also be brought into requisition perhaps, and that is the *Equisetum* or Mare's-tails; sometimes we meet with them in bouquets of flowers, and the singularity of their growth is at all times pleasing. Could one of these be induced to put on a yellow livery it would be received as a boon. Other wild plants, equally beautiful, might also be found. Some years ago an *Oxalis*, I think of wild origin, was admired by some, its foliage being of a bronzy-red colour, and *Ajuga reptans rubra* is assuredly also of British origin, and both plants had their admirers. Am I not right in supposing the Golden Pyrethrum of the present day also to be the offspring of a plant common in our woods?—A RETIRED GARDENER.

STOBÆA PURPUREA.

MR. HEMSLEY in his description of this plant last week (p. 12) says, "to grow it in perfection in the open air, some little attention is required as it is not perfectly hardy." Surely this must be a mistake. In February my first seedlings made their appearance, and as soon as they were strong enough to handle, they were pricked off into 5-in. pots. In these they grew rapidly, soon filling the pots with roots, and compelling me to have them potted off sooner than I had intended. The strongest were potted in 3-in. pots, the smallest in "stores," in which they remained until the latter end of April, when they were planted in the open ground; they were dibbled in in the same way as one would do Cabbage plants, merely shading them for a few days, and I do not think that I lost one in a hundred. They grew rapidly, and by the end of June they began to throw up their flower-spikes; these were at least 3 ft. in height and bore on an average twenty-five blossoms on each; they flowered beautifully and were the admiration of everyone, lasting in good condition for a month or six weeks. I gathered from them a good supply of seed and then left them to take their chance. During the whole of the first frost all the plants, both in pots and in the open ground, were unprotected, the pots being not even plunged. After the frost had gone I examined them and found them breaking up strongly from the bottom, some having three, four, and even six crowns. I then thought it prudent to remove them in case of more frost, so the pot plants were placed in a cold frame and those in the ground were covered with straw. I have examined them again to-day, and I find them, both in pots and in the ground, uninjured. Any plant that will stand the test of such a winter as we have had and are still having, in such an unfavourable locality as that of Tottenham, must, I think, be perfectly hardy anywhere in this country. A. P.

CANNAS ON THE CONTINENT.

I HAVE read Mr. Cornhill's remarks on Cannas with much interest; having considerable experience in their growth, I have no hesitation in saying that his instructions as to their treatment and propagation are correct. It is important that the soil in which Cannas are grown should be deeply moved, at least two spades or more, for although the roots do not go very deep, they require the soil to be light and well drained, notwithstanding their liking for plenty of moisture. It has been often stated that Cannas cannot be cultivated for several years in the same soil, but that is a mistake. I have grown them for many years in the same place at the bottom of my garden, shaded by trees, and protected from wind. They grow with me most luxuriantly. As to wintering them, it is, as Mr. Cornhill writes, exceedingly easy, provided they are protected against frost. I am not, however, partial to shaking off the earth from the roots. I have tried it, but have found that when I left the whole of the earth amongst and outside the roots, they were stronger the next year.

In November, before frost is probable, I lift them with the spade, and put them under the shelves of the greenhouse, and there, when they appear dry, give them a slight watering to keep them moist. I tried to leave them the year before last in the ground, being laid up in November by illness, and not confiding the treatment of my plants to any one, but, as the winter was very damp, they were all rotten next spring. I think it, therefore, advisable to lift them, to preserve them from too much moisture and frost. As to the varieties named by Mr. John Cornhill, I must answer his appeal by giving your readers the names of a few of the best, and I will give them according to their height:—*Bariletti*, the best of all as to foliage, seldom blooms from 8 ft. to 9 ft.; *Auguste Ferrier*, foliage also beautiful, from 7 ft. to 8 ft.; *nigricans*, brown foliage, 7 ft. to 8 ft.; *Imperator*, green foliage, 5 ft. to 8 ft.; *Jacques Plantier*, green foliage, 6 ft. to 7 ft.; *insignis*, green with brown, 6 ft.; *Député Henon*, green foliage, 5 ft. to 6 ft.; *Maréchal Vaillant*, brown and green, 5 ft. to 6 ft.; *Daniel Hooibrank*, green foliage, 5 ft. to 6 ft.; *Premie de Nies*, green foliage, 5 ft. to 6 ft., one of the best for blooming; *Jean Bart*, brown and green foliage, about 5 ft.; *Jean Vandaal*, brown with green foliage, 4 ft. to 5 ft.; *Edouard Morren*, green foliage, large yellow flowers, spotted with dark orange, 4 ft. to 5 ft.; *Bihorelli*, green foliage, free bloomer, 3 ft. to 4 ft.; *Picturata Nana*, green foliage, very free bloomer, 2 ft. to 3 ft. It must not be forgotten, that the mulching recommended by Mr. Cornhill is not sufficient, and that Cannas, to come to perfection, require frequent watering with liquid manure, and what they like best is nightsoil, deodorised by means of sulphate of iron.

Ljoms.

JEAN SISLÉV.

PLATE CLIX.

RHODODENDRON LEPIDOTUM.

RHODODENDRONS, or "Rose trees," are scattered all round the northern hemisphere, but the greatest concentration of species occurs in the Himalaya mountains, the home of the present species. Here they form a characteristic feature of the woody vegetation in certain localities, and especially at great elevations. They vary from a few inches high, as *R. nivale*, to 40 ft., with a trunk sometimes exceeding 14 ft. in girth, as *R. arboreum*. The former is found almost at the extreme upper limits of vegetation of flowering plants, at least, having been collected by Sir J. D. Hooker at an elevation of 13,000 ft. *R. lepidotum*, although it does not ascend to quite so great an altitude, is an Alpine species, occurring between 8000 ft. and 16,000 ft., according to the nature of the locality, but it is most at home between 10,000 ft. and 15,000 ft. above the sea level. Having so great a vertical range, it naturally varies considerably in stature, in the size of the leaves, and in other minor details. The forms *R. salignum*, *R. obvatum*, and *R. elaeagnoides*, originally published as distinct species, have proved to be no more than varieties of one type. Each of these varieties, which are distinguished in the extreme states from each other mainly by differences in the foliage, varies in the colour of its flowers from yellow and pink through divers shades to dark purple. In all its numerous forms this species is characterised by having the upper surface of the leaves, as well as the lower, and the flower stalks, clothed with circular brown scales. It is also highly resinous, emitting a powerful odour under the influence of sunshine. In its upper habitats it is of a gregarious nature, growing 1 ft. or 2 ft. high, and extending laterally into large clumps. Lower down in the mountains it attains a height of 4 ft. or 5 ft., but is of somewhat straggling habit, with naked, twisted, and crooked trunks and branches, terminating in tufts of slender branchlets. The leaves are clustered near the tips of the branchlets, and rising above the foliage are from one to four flowers. Several of the varieties mentioned above have been introduced into our gardens, as well as one called *chloranthum*, with pale yellowish-green flowers.

W. B. HEMSLEY.

[The plant from which the annexed figure was prepared was supplied from the Lawson Company's Nurseries, Edinburgh, where it is found to be perfectly hardy. It is a very free bloomer, having flowered in the nursery in question in a very small state, and most of the plants now in the open ground have plenty of flower buds on them. The severe frost which we have experienced this winter has apparently had no injurious effect upon them.]

AN INDIAN ALPINE RHODODENDRON. *R. LEPIDOTUM*. WZLL.

GARDENING FOR THE WEEK.

Conservatory.

More pleasure, as a rule, is derivable from a well-furnished conservatory during the next three months, than at any other time of the year, inasmuch as during that period there are less attractions in the outside garden. This is especially the case where the conservatory is attached to the dwelling, and, consequently, accessible without exposure to the weather. Everything possible should now be done to keep it as attractive as possible by means of the regular introduction of forced flowers, prepared elsewhere, and the arrangement of them along with the permanent occupants of the house, in a way that will produce the best effect. Attention given to this is time well spent, for it frequently happens that with a moderate quantity of fine-leaved and flowering subjects judiciously placed, a much more artistic effect is given than in other instances where there is an unlimited quantity of material at hand, but an absence of ability to use it to the best advantage. There are few matters connected with the ordinary routine of a garden, in which those in charge have a better field for displaying ability above that of the nominal plant grower, than in that of conservatory arrangement. There is no doubt that a good deal of the effect possible to be produced, depends upon the internal construction of the building. To make anything like an effective arrangement there should be nothing in the shape of a fixed stage, as the presence of such prevents the possibility of effecting the requisite changes in the grouping, that from time to time should take place, so as to obviate the objectionable monotony of seeing a considerable number of the regular occupants of the conservatory always in the same position. During the next three months *Camellias* will play an important part in the arrangement here, especially where there is a sufficient number of plants proportionate in size to the dimensions of the house which they occupy. If these be arranged so as to act as a background to forced *Azaleas*, *Cytisus racemosus*, *Epacris*, *Correas*, hardy shrubs, *Cinerarias*, *Primulas*, forced bulbs, standard *Tree Mignonettes*, *Salvias*, *Epiphyllum truncatum*, &c., in combination with *Agaves*, *Dracanas*, *Yuccas*, *Cordylines*, *Dasylirois*, *Lomatias*, *Phorium tenax*, *Tree Ferns*, *Cycads*, and *Macrocarpas*, a collective effect may be made not easily surpassed at any season of the year. Where a good supply, in small pots, of *Lycopodium denticulatum*, *Isoetes gracilis*, and *Centaureas*, is at hand, they will be found most useful in hiding the larger pots.

Roof Climbers.—So far as these are concerned, there are few that, just at the present time, will contribute much by their display of flowers, but they should be all carefully gone over, and so far cut in as to prevent anything like crowding, or their spreading under the whole roof surfaces in a way that will too much exclude light. In securing them in their places, the objectionable practice of tying them in so tightly as to give the whole a stiff appearance should be avoided. On the contrary, a sufficient number of shoots should be left hanging in a pendant position to prevent this. Where insects of any description are troublesome, they should be thoroughly cleaned while the plants are comparatively in a dormant condition. For a like reason, and to enhance the general appearance, all the permanent occupants should, as often as time can be found, have their leaves sponged; this is the most necessary at this season when the syringe and garden engine are better not used.

Temperature and Air-giving.—The temperature of conservatories should be from 46° to 50°, in the night, according to the weather, with a proportionate rise by day; this, as a matter of course, will necessitate an almost continuous use of fire-heat, to avoid the over-drying influence of which sufficient moisture must be given in the immediate vicinity of the pipes, otherwise the air will get so dry that its effects are certain not only to be seen in causing the unexpanded buds of *Camellias* to fall off, but it will also act injuriously upon other plants. Be very careful about the admission of air, even at such times as the sun happens to shine out clear and bright, giving it, as far as possible, at the roof. Much better let the thermometer rise considerably on the few occasions that it may be expected to do so for several weeks hence than admit a volume of cold air in direct contact with the plants.

Greenhouse.

Where hard-wooded plants are only required for home decoration, and consequently there is no danger of the branches rubbing and chafing against each other when being moved the short distance they have to be conveyed from one house to another, no more stakes and ties should be used than are needful to support them in a form similar to that which each plant, according to its kind, assumes in a state of Nature. When plants are wanted for exhibition purposes they must of necessity have the requisite quantity of sticks and ties to keep their branches steady, or in transit the flowers are certain to be

destroyed. This applies not only to hard-wooded greenhouse plants that usually come under this designation, but also to *Cape Heaths* and *Azaleas*; but, in the case of the latter, such tying as they require should never be deferred till this time of the year, being much better done towards the close of summer, before the season's growth becomes solidified, as then the points of the shoots and foot-stalks of the leaves, whilst yet soft and flexible, will in a few days regain their proper position, from which, in the work of tying, they have been bent; this will never take place if the plants be left until the wood has got hard and ripe—a circumstance which adds much to unsightly formality.

Winter-flowering Heaths.—As soon as these have done blooming, they should be at once cut back, so as to cause the principal shoots to break low enough to keep them from assuming the straggling condition they will get into if left to go on for another season without the last summer's growth being sufficiently reduced.

Primulas.—Both the single and double varieties should, where possible, be kept in a light house or pit, where they can be accommodated with a night temperature of from 45° to 50°, keeping them as close to the glass as circumstances will permit. The plants of the single varieties intended for later flowering should be some degrees cooler than this, and all must be watered with care, as if the foot-stalks of the leaves get much wet they will be liable to decay.

Cyclamens.—To grow these plants well they should be treated through the winter as to temperature much in the way recommended for *Primulas*, as, unless kept a little warmer than an ordinary greenhouse, they will not grow or flower anything like what they are capable of. Keep a good look-out that there are no apices upon them, otherwise they get established in quantity on the young advancing bloom-stems without being noticed, in which case they will cause the flowers to come deformed.

Cinerarias.—If a sowing were made sufficiently early, and the plants have been well attended to through the season, they will naturally have come on into flower without anything above the usual greenhouse treatment, to which they should never be subjected, as even a very little heat injures them by destroying the under leaves and drawing the bloom-stems up thin and weakly, which spoils them for the general purposes of decoration, and if the flowers are wanted for cutting makes them comparatively worthless, as they flag directly. Keep the successional later-blooming plants as cool as possible, so that they are out of the reach of frost; by this means they may be had to flower in good condition up to the middle of May, during which period they will be found most useful, as they furnish shades of colour, especially blue, not only beautiful in themselves, but such as much enhance the effect produced by flowers of other colours with which they are associated, either in the conservatory or in a cut state.

Herbaceous Calceolarias.—Plants raised from seed sown last summer, and afterwards potted off singly, should at once be attended to by moving them into larger pots before their roots get at all confined, for if this occurs, the stunting influence will be such that they never afterwards can be induced to grow on freely, or to attain anything like the size and ability to produce such a quantity of flowers as when encouraged by liberal treatment. It is seldom we now see these useful decorative subjects so well managed as they are at one time were. If, as may be supposed, they are occupying 3-in. pots, a portion may be moved into others that are 4-in. or larger, in which they can be allowed to bloom. Those that are intended to have a second shift in addition to the present, may be transferred at this time to 6-in. pots. They delight in rich, light soil, such as is composed of two parts good, free, turfy loam, with a third part consisting of equal proportions of leaf-mould and rotten manure, all mixed up with sufficient sand. In potting, avoid the extremes of leaving the soil so very loose as at one time was looked upon as conducive to their well-being, and also the opposite of compressing it in the pots to that degree of solidity necessary with *Pelargoniums*. The plants should have a light position in a pit or house that can be kept at a temperature of about 40° in the night, with a moister atmosphere than many plants require.

Shrubby Calceolarias intended for flowering in pots should be similarly treated, but in practice I have found that these do better with potting somewhat harder than the herbaceous species. Both should be from time to time examined to see that they are free from green fly, as, if this pest is allowed now to get established upon them, it will spoil the appearance of the plants, will weaken them by the destruction of the lower leaves, and be much more difficult to eradicate than if taken in time. Where only a few individual plants amongst a number are affected, dipping in Tobacco water will prove an efficient means for the destruction of the insects, or they may be killed by fumigation, but, where this is resorted to, it will be safer to

repeat it slightly several times than to subject the plants to a severe application, as they are much easier injured by Tobacco fumes than many subjects.

Show and Fancy Pelargoniums.—Plants of these that after being cut back were shaken out and replaced in small pots, if not already transferred to those in which they are to bloom, should be attended to, as with them also, any approach to a root-bound condition will stop growth and proportionately weaken their flowering capabilities; good turfy loam, of not too light a nature, well enriched with rotten manure and a little sand added, is necessary to grow these plants satisfactorily, and, in potting, the soil can scarcely be made too solid, by ramming it tightly in with the potting stick. When it is left too light, there is always an inclination to run too much to leaf, with a comparative indisposition to flower. As soon as potted, they should at once be tied into shape, avoiding the over-formality consequent upon the unnatural trellis style of training sometimes resorted to, likewise that which leaves the branches with so little support that the plants cannot be moved when in flower to wherever required, without the stems falling about in a straggling unsightly manner. The fancy sorts, from their more sturdy growth, stand in less need of support, but both kinds should be trained sufficiently open to admit of plenty of light getting to the whole of the leaves, and to preserve a stout, bushy outline, which is their natural habit. Keep them, if possible, within a short distance of the glass in the lightest house available, and be careful for the next two months never to give water until the soil has got drier than it would be advisable to allow it in the case of most plants.

Chrysanthemums.—If cuttings of these are not put in, no time should be now lost. Chosse shoots that are stout and strong and have not been drawn up weakly, for, though the latter will root freely enough, they are a long time before they acquire strength. I should not by any means recommend their being put in heat to induce them to root, as is frequently done, as this has a direct tendency to cause top growth, which it is most desirable to avoid until roots are formed; the foliage made under such conditions is necessarily so soft and devoid of fibre that it does not admit of being kept alive on the plants, which leaves them bare at the bottom. They will strike easily but slower inserted in a mixture of one-half loam and sand, covered with ordinary propagating glasses in a greenhouse temperature kept near the glass. It is advisable to see that they are free from aphides before putting them in. If the plants from which they are taken have been at all affected with these it will be better to dip the cuttings in Tobacco water previous to insertion.]

Orchids.

Phajus.—*P. albus* and *P. Bensoni*, if not done growing, should be kept at the warmest end of the house, and supplied with sufficient moisture to maintain a healthy root action.

Calanthe veratrifolia will, in most cases, be about completing its growth; and the loam or peat, whichever it is grown in, should be kept only slightly moist.

Such species belonging to the families of *Cattleya*, *Lælia*, *Dendrobium*, *Oncidium*, and others, the growth of which is progressing at this season, and which, during that time, usually are removed to the East Indian house, should have as much moisture given to the roots as will assist them to complete their growth.

Intermediate House.—A temperature of from 48° to 50° in the night for some time, with 5° or 6° more during the day, will be about the right heat. Most of the warmer section of *Dendrobies* now at rest will find a suitable place here. The large, erect-growing species, such as *D. Calceolaria*, *D. Dalhousianum*, and *D. Paxtoni*, are not so much cultivated now as they used to be, no doubt on account of their tall, rather straggling habit, but even after being well managed so as to produce stout, fully-matured pseudo bulbs, they need to be well dried up to induce them to flower freely; the drying must be continued, without any application of water, right through the winter and spring till they show flower. If water be given previous to this a considerable number of the buds will run off into growth. The increase of atmospheric moisture, with a higher temperature later on in the spring, will be sufficient to cause the bulbs somewhat shrivelled to plump up and get through the first stages of the flower's development without the application of water to the roots. The short, thicker-bulbed section of *D. densiflorum*, *D. Farmeri*, and *D. clavatum* character, require a lengthened period of dry treatment at the roots, but their flowers do not run off into growth by the application of a little water at the roots if it becomes necessary to give this to prevent their shrivelling too much. The thicker-bulbed, drooping kinds, such as *D. Wardianum*, *D. macrophyllum*, *D. chrysotis*, and *D. primulinum*, are all free flowerers, and if they appear to be getting too much shrivelled may have now and

then a small quantity of water given them through the winter without its interfering with their flowering. The beautiful *D. Falconeri* requires well drying to induce it to bloom freely, and should have very little moisture given it before the flowers are unmistakably apparent or it will run off into growth. The equally beautiful *D. Devonianum*, and a few others of like character, also need a longer season of dry root treatment than most Orchids, but they commence to grow previous to the development of their flower buds, and require water to assist the growth in the spring before these make much progress. *Cattleyas*, *Lælias*, *Epidendrums*, *Brassavolas*, *Brassias*, *Broughtonias*, *Barkerias*, *Angulos*, *Miltonias*, *Chysis*, *Cycnoses*, *Eriopsis*, *Gongoras*, *Lycaestes*, *Mormodes*, and *Oncidiums*, with few exceptions, will succeed with similar treatment as to temperature and a moderately lengthened period of dry condition at the roots previous to the development of their flowers.

Cool Orchids.—The house devoted to these should now be kept at from 38° to 45° in the night, and 5° or 6° higher by day, according to the weather. The principal plants to be considered in this department are the *Odontoglossums* and *Masdevallias*, both of which, but especially the latter, must never be submitted to drying treatment at the roots. The different other cool species that need total rest through the winter, during which time they require to be kept dry, may be treated in this way so far as will not entail much shrivelling, which is not likely to occur, as the atmosphere here will not be nearly so dry as that where more fire heat is used.—T. BAINES.

Flower Garden.

At this comparatively cheerless season, nothing renders a garden more thoroughly enjoyable than dry and neatly kept walks. Now is the time for making new ones and improving and renovating those already in existence. If the gravel be discoloured or Moss-grown, break it up with forks, and leave it loose until rain has fallen; then rake it over and roll it down, when the walk will look as if fresh gravelled. Walks under the shade of trees and shrubs where there is no Grass to be killed, need not be broken up, as a sprinkling of salt will both kill the Moss and give brightness to the gravel; but for use in open spaces salt is not to be commended, as, even with the greatest care, it frequently kills the Grass verges, and after a time it acts as a manure, and increases rather than diminishes weed growth. Levelling turf and relaying it should be forwarded as fast as the weather permits; also all grubbing, trenching, and alteration. Leaf clearing should ere this be completed, and now the shrubby borders may have their annual pointing over, an operation which is necessary, not so much for the benefit of the shrubs as for the removal of weeds and the fixing of blowing leaves. Herbaceous borders are now looking weedy, and where, as is usually the case, such borders contain large clumps of bulbous plants, not much can be done to improve matters till these show themselves above ground, but as soon as they do so, contemplated rearrangement and division of the plants may be proceeded with, and the borders may be manured and dug as deeply as the occupants will permit. Several kinds of plants that have of late withstood our mild winters have succumbed to the late severe frost. *Eucalyptus globulus*, not protected, is quite dead, while those that were covered with Bracken are alive, so far as the protection extended, and so are the Australian *Dracenas*, which have stood out during the past four winters unharmed; those not protected are dead, but the others, though much injured, are alive; it therefore becomes a question how much frost can even a little covering keep off. Such covering should be applied now to plants that have weathered the storm, for their constitution being weakened, such another frost would be very likely to kill them. Roses do not seem to have suffered at all, but as a safeguard, the beds should now be thickly mulched with manure, which will also serve as protection. If the weather be open and favourable, the sooner all intended planting of Roses is completed the better. Standards and others requiring support should be staked at once, to prevent injury from high winds, and the beds should be mulched as before recommended. Beds of *Anemones*, *Ranunculuses*, and choice *Hyacinths* and *Tulips* that are peeping above ground will be all the better for a covering of Spruce or Laurel boughs laid thickly over them. *Echeverias* have suffered severely, and the reserve stock must be looked to, in order to see that no losses occur amongst them. All other bedding plants, more particularly those required in quantity, must be examined, and tender kinds introduced into heat for the production of cuttings. See that roots of *Dahlias* and *Cannas* are secure from all danger from frost; the middle of February is sufficiently early to introduce them into heat.—W. W.

Auriculas.—After the disappearance of the severe frost, and when the frames had been well opened up a few times, it was seen that quite half the outer leaves of our *Auriculas* were injured; these have now been removed, and only the centre tufts of late

autumn-formed leaves left. Still admit plenty of fresh air, and remove the lights altogether during fine weather.

Carnations and Picotees.—Ventilate frames in which these are growing, freely; but let no rain fall upon the leaves. Raise the lights by tilting them on blocks, and in fine weather remove them. If there be any traces of aphides on the leaves, fumigate on calm nights until they are destroyed. A pair of sharp-pointed scissors is useful to cut off portions of decayed leaves. Plants in beds must be looked over occasionally, and those not steady in the ground must be made firm by pressing round the base of the plants, and a neat stick should be placed to each in order to prevent any injury from high winds.

Dahlias.—The roots of these are sometimes injured by being stored in unsuitable places, such as those that are either close and damp, or too dry. It is well, therefore, to examine them carefully. I have seen a collection of fine sorts injured from the roots being quite desiccated by being placed too near the hot-water Pipes in a Mushroom house. Close, damp sheds, too, with a northern exposure do not answer. If the roots are not keeping well, look over them, remove decayed portions, and place them in boxes in dry mould, removing the boxes to a Vinery, Peach house, or other structure from which frost is excluded.

Hollyhocks.—The leaves of these in frames show the effect of the severe frost which we have experienced, therefore all decayed leaves and portions of leaves should be removed at once and air should be given on all favourable occasions, excluding damp. In foggy or close, wet weather, it is best to keep the lights closed, mould soon gathers on decayed portions and must be looked after. Plants in pots in houses from which frost is excluded are not likely to suffer any injury; they must not, however, be allowed to become overdry at the roots.

Pansies.—Favourable weather should be taken advantage of, to pot such plants as are intended for pot culture; 6-in., 7-in., or 8-in. pots answer best, and either one of these sizes may be used, according to the convenience of the owner. One plant, if large enough, will be sufficient for a pot, but small plants may be utilised by placing two or three in each pot. The soil ought to consist of about four parts turfy loam, one rotten manure, one leaf-mould, and one sharp sand. Press the mould in firmly with the fingers round the roots of the plants, and see that plenty of drainage is placed in the bottom of the pots.

Polyanthuses.—These require similar treatment to Auriculas, but it is not well to allow the roots to become too dry. The trusses, too, are formed earlier than those of Auriculas. The plants require plenty of ventilation, and the leaves being more fragile and brittle than Auricula leaves, are also very liable to be attacked by insect pests. Red spider, thrips, and green fly attack them even in winter; these must be destroyed by washing the foliage and fumigating the frames. It is worthy of notice that the leaves are seldom attacked when the plants are in good health. Plants of these or of Auriculas in beds must be seen to, and if the roots be exposed, carefully dress the surface between the plants with light, rich soil, pressing down the plants rather firmly. J. DOUGLAS.

Indoor Fruit Department.

Vines.—The earliest house will now be advanced towards the disbudbing stage, and this should be done with judgment. As a rule, one shoot to a spur is sufficient, but where the Vines are a sufficient distance apart to permit of the full development of the extra foliage, two shoots are best. Keep up a genial average temperature of 65°, and allow the heat to fluctuate somewhat with the outside temperature, and, if the Vines must be pushed on, let it be by day firing, accompanied by daylight, as it is only natural that Vines, like plants of other descriptions, should have their night season of rest, which can only be attained by keeping the temperature as low as is possible compatible with the health and due progress of the Vines. The roots of early forced Vines should be confined to inside borders, and when water is required it should be warm, say from 90° to 95°; the warmth thus communicated should be retained as long as possible by immediately mulching with a thick layer of litter fresh from the stables, the ammonia arising from which will also supply an element as regards successful culture. Thus treat all borders now where the Vines are expected to produce ripe fruit in June next. Early Vineries that have outside borders should have been covered with straw, Bracken, or leaves early in October, to retain the heat deposited in them by the summer sun, and shutters or other covering should be used to throw off snow and heavy rains. In this manner a more equable temperature is maintained than by the questionable method of hotbed heating, the fluctuations of which are so great. If a bed, 2 ft. in thickness of leaves and stable litter, can conveniently

be kept inside the Vinery, it will serve the double purpose of increasing the temperature and obviating syringings, and it will also help the expansion of buds. In mid-season houses, as soon as the fruit is cut, forthwith prune the Vines and they will go more effectually to rest. Indeed, to do them justice, all Grapes should now be cut and put in bottles of water; they will keep better if cut now than if left on the Vines another month. Any dry room in which a temperature can be kept above 40° is suitable for the purpose, and as much wood as possible, both behind and in front of the bunch, should be cut along with it to act as a deterrent to an overplus of moisture being communicated to the fruit.

Pines.—Ripe fruit for the London season is generally required in quantity; therefore Queens that are now showing fruit should be encouraged accordingly. Thus managed, they will be ripe from the beginning of May and onwards. A bottom-heat of 85° should be maintained, and an atmospheric heat ranging from 55° on cold nights to 75° or 80° on warm days, should be kept up. To all plants showing fruit give a soaking with water at 80°, and they should not again be allowed to become dry, nor, on the other hand, should they be kept constantly wet. Any expected to show fruit, and that as yet manifest no signs of it, should be kept dry; the check thus given rarely fails to produce the desired effect. Succession plants at this season require great watchfulness; the weather, having been severe, has necessitated hard firing, and they will have become very dry, a circumstance which is apt to cause them to fruit prematurely. It is better to cover the pits with mats, &c., at night, thus not only saving firing, but inducing sturdier growth. Atmospheric acidity is a great foe to successful Pine culture. To plants swelling off fruit at this dull season afford every attention; water with tepid guano water whenever they seem approaching a dry state; a humid atmosphere of 75° is desirable, and all the sun and light they can get; therefore, the glass should be kept scrupulously clean. Leaves for plunging preparatory to the general shifting which must soon take place, should be stored and allowed to consolidate. Soil should also be got under cover, and everything should be in readiness for action as soon as a mild period has arrived.

Peaches.—These do not like excessive forcing. Failure, or rather partial failure, has more than once been the result of attempting to force Peaches against time. The earliest houses are apt to drop their buds previous to expansion; this is generally attributed to the trees having suffered from drought the previous season, but, though this may occasionally be the cause, a more general one is the undue excitement of the buds by beginning to force with too high a temperature. Forcing should be very gradual till after the fruit is set, and then, if necessary, a push may be made up to the stoning period, when excitement again becomes dangerous, but, after that, hard forcing is safe enough. In starting to force a house, see that the border is thoroughly moistened throughout, and do not exceed at night 45°, and, as in the case of Vines, prefer rather to fire by day, with the accompaniments of light and air, than at night. Syringe night and morning trees, walls, and floors till the blooms begin to open, when a drier atmosphere is requisite. Prune late houses; wash or paint them over, as a preventive against insects, with soap-suds, Tobacco water, and sulphur, made to the consistency of thin paint by adding clay or cow manure to cause adhesiveness. This done, top-dress the borders by removing all the loose, inert, top soil, and replacing it with good loam; a little bone-dust, wood-ashes, or powdered charcoal. Peach borders in either early or late houses should never be allowed to get dry, and, if the drainages be good and there be a free outlet, there need never be any fear of the borders getting too wet. New borders in course of formation should be completed as soon as possible as it is quite time the trees were planted if good growth be desired this season. A good Peach-producing soil should consist of loam of medium texture, rather stiff than light, chalk or lime scraps, and charcoal. Manure, if required, is best applied in a liquid state when the trees are in full vigour.

Strawberries.—Having no Strawberry house, our first batch (200) has been started in a pit filled with Oak leaves to create warmth. The plants are not plunged but simply set closely together on the bed; here they have abundance of air, and the crowns soon start into active growth. They are gradually removed from this pit to fill shelves in Melon and Peach houses, according to the expected demand, and now our first batch—Vicomtesse d'Hérécourt de Thury—is throwing up their flower stems most sturdily, a fact attributable rather to the strength of the plants than to the culture which they have had since being introduced to the forcing pit. Large, well-ripened crowns, constitute the acme of success in Strawberry forcing. At this early and sunless period, as soon as the blossoms open, artificial distribution of pollen is requisite in order to insure a good set. Plenty of rarified air is beneficial, and, indeed, necessary, but cold draughts prove fatal, and so does a muggy atmosphere. Keep the

plants moist, and use for the present clear, tepid water only. Protect the later plants from heavy rains and severe frosts. All should be housed in cold pits, but, lacking that convenience, plunge them in ashes or leaves, and cover with shutters or tarpaulin as may be required.

Melons.—For fruit required early in May sow at once, and, in order that they may germinate kindly, they will require a bottom heat of 80°. The seeds should be put in pairs in 3-in. pots, and, when up, the weakest plants should be destroyed. When sown, as is frequently the case, a number of seeds together, the check caused by division is considerable. Grow the plants as near the glass and with as much light as possible. A shelf in a Pine pit is a much better position than if plunged in a bottom heat a long distance from the glass.—W. W.

ROSES.

SHIELD BUDDING AND GRAFTING.

CHOOSING THE SHOOTS FROM WHICH THE SHIELD-BUDS ARE TO BE TAKEN.—This choice is all the more important seeing that the constitution of the eye to be shield-budded has a great influence not only on the vigour of the resulting Rose bush, but also on its inflorescence and longevity. An eye taken from a strong shoot, for instance, will cause a luxuriant growth of leaves, forming a bush with a beautiful head, but with very few flowers. An eye taken from the lower part of a shoot develops but slowly, and remains a long time dormant. A bud taken from the angle of the last two leaves immediately under the flower stalk of a Rose tree which, under ordinary circumstances, is intended for flowering purposes will, when grafted, induce a precocious inflorescence and interfere greatly with the growth of the Rose tree. As the flower is formed on the extremity of the shoot, the growth of the latter will be stopped and the sap will be sent back to feed useless shoots and growths. This description of bud is, however, sometimes used exceptionally, in order to produce several successive flowerings in varieties which bloom with difficulty. It is, therefore, mostly from the middle of the shoots that we must choose the best buds for shield-grafting. The shoots chosen should be healthy, sufficiently mature, and full of sap, and the buds themselves should be vigorous and well-formed, and of dimensions proportionate to the stock upon which they are to be grafted. We may always ascertain whether a branch or shoot is full of sap or not by its extremity being herbaceous and continuing to grow, besides which we may recognise the fact by the sap oozing out of the incisions made when we cut out the shield-bud.

PREPARING THE STOCKS FOR SHIELD-BUDDING.—If shield-budding is not performed upon the spot, the shoots chosen are cut off, and the top, which is generally more or less herbaceous, is pruned away. The leaves are also removed, the lower half of the petiole alone being allowed to remain. The shoots are tied up into little bundles and numbered, and are either kept wrapped up in a damp cloth, or else their lower ends are plunged into a vessel of water, so as to keep them fresh and moist. These precautions are sufficient if the spot at which they are to be used is not very far off, or the time not very distant; but if, on the other hand, they have to be used at a distance, they are piled up in gradually decreasing layers on a bed of slightly damped Moss, so that they may form a kind of cone or sugar-loaf, which is packed up in paper, and secured with string. If, after having cut off the shoots, we find any shoots with wrinkled bark, or with eyes which seem to be too small, they should be soaked in water for twenty-four hours, when the bark will become smooth and the buds will swell out. When we have stock plants from which we can take the buds, it is a good plan to examine the shoots some time previously, so as to know the exact condition of the eyes. If they be flat and small we need only pinch off the end of the shoots about a week before taking off the buds. This operation has the effect of sending back the sap into the buds, and of causing them to swell out very rapidly, so much so that they will push into shoots if we delay cutting off the slips too long.

SHIELD GRAFTING WITH A GROWING EYE.—If, as we have said before, the operation of pinching off has been properly carried

out, and the shoots are sufficiently strong and solid, we may begin to graft in June, which will allow us later on to take buds with dormant eyes from the shoots of these grafts. In the climate of Paris this operation is performed at the end of June or during the month of July. The two important conditions to be fulfilled is, to have subjects with healthy shoots, full of sap, and with well-formed eyes on the grafts. We may begin grafting even earlier than this if we chose our buds from plants which have passed the winter in a greenhouse. Some days before budding we choose a sufficient number of subjects for the purpose, bending down the shoots to be budded, and tying their tips to the stem of the Brier stock. By this means the sap becomes concentrated in the elbow of the shoot, which greatly favours the development of the grafted bud. A fortnight or three weeks after the grafts have been put on we must examine them to see if they have taken. We can easily judge whether this has happened by observing whether the petiole has fallen off, and the bud itself is quite fresh and green. If so, we may remove the ligatures so as to avoid undue compression and possible fracture of the shoots. As the buds grow into shoots we must pinch off the tops of all the shoots as soon as they are long enough. When the shoots of the graft have reached the length of 8 in. we may prune them back until only two eyes are left. With dwarf Rose trees we must bend down the young shoots and fasten them down by means of hooked pegs fixed in the ground. Grafting with a growing eye allows us to multiply new varieties with great rapidity, and is of good service when the frost has destroyed the grafts made with dormant buds. It is also useful for supplying us with shoots for budding the grafts of the year before.

SHIELD-GRAFTING WITH A DORMANT EYE.—This kind of grafting is carried on in the neighbourhood of Paris from the middle of August to the end of September. This period may be anticipated or exceeded according to the temperature. As in grafting with a growing eye, we must use shoots with properly-formed and healthy eyes, but the sap, instead of being in full activity, ought to be rather on the decline. There must, however, be sufficient sap in the bud for it to take when grafted, but not enough for it to develop into a shoot. In this case the eye will lie dormant until the spring. In order to prepare the subjects to be budded, we must examine them a week or a fortnight before the time for grafting arrives, and pinch off the tips of all the shoots on the branches to be budded, as well as the smaller shoots. In the neighbourhood of the place where the graft is to be made, the shoots allowed to remain on the top of each branch must be reduced to two or three, rarely more. All the others must be cut down as they grow, otherwise the sap will receive a check, wasting itself through the wounds of the cut branches. It is better to leave them as they are than to interfere with the flow of the sap. The shield-buds should be placed at the angle of the stem and the shoot, two or three on each subject, according to its health and the number of shoots which have been allowed to remain. When a subject has only one branch fit to be grafted with a shield-bud, we may graft it a second time by placing another shield-bud on the opposite side of the stem to the first one. If the branches left are too weak, we may graft two shield-buds on the stem itself underneath the branches, as shown in Fig. 24, A and B. In the case of dwarf Rose trees, we should graft two shield-buds on the lower part, about 3½ in. from the ground, as shown in Fig. 24, but, in order to succeed, we must have young subjects with smooth bark. When the shoots of the grafts are well forward the ligature is taken off, and the branches and upper portion of the stock at C, as shown in Fig. 24. In the other cases the stems and branches are cut off just over the bud, which is immediately above the last graft. This shoot is destined to bring the sap into the branch, and provide food for the buds. It is cut off along with the part of the stem upon which it grows when the buds are old enough to take care of themselves. Having pruned the branches, we must protect them from being broken by the wind with sticks of 1 ft. 4 in. to 1 ft. 8 in. in length. The stick is placed against the base of the branch, and it ought to be 1 ft. taller than the last bud. As the shoots increase in size they are trained against the stick, by which means we avoid the danger of breaking them or tearing them from their position.

PINCHING BACK THE FIRST SHOOTS.—The end to be aimed at during the year which follows the operation of shield-grafting is not so much that we should obtain a number of flowers, as that we should form a Rose bush with a good head. We must not, therefore, hesitate to pinch back the new shoots to within three leaves of the top, whether there is, or not, any provision for flowers, as soon as ever these shoots have reached a proper size. The sap is checked by this operation, and is thrown into the side shoots, causing them to swell and very frequently to yield a mass of flowers that will fully compensate us for the loss of the earlier flower buds.

COLLAR GRAFTING.—The third method of shield-grafting consists in opening a small trench along the line of the subjects about to be grafted, so as to lay bare their bases, which must be well cleared of mould with the fingers. Two or three

Fig. 24.—Grafting by Double Shield-budding.

shield-buds are then grafted on the principal roots at the spot where they join the stem. Before the cold weather sets in, indeed, as soon as the grafts have taken, the ligatures are removed and the trenches are filled in, so that these grafts are not uncovered, or the trees pruned, until the first fortnight in March, by which time there is generally no longer any danger of frost. By this mode of grafting it becomes easy to obtain free stocks, especially in the case of Hybrid Roses, by means of the roots which spring from the collars of the graft below ground. This modification in the method of shield-grafting also places the buds beyond the reach of frost. It is by adopting this method that the Rose growers of Lyons have for several years used young seedling Briers, upon which they have grafted their dwarf Roses, by shield-budding the collar of the root. This method gives very good results, so far as the growth of the graft goes, but in no way modifies the spreading nature of the Rose tree. We have been able to verify this fact at the establishment of M. Lévêque, fils, of Ivry-sur-

Seine, in the case of some Tea and Hybrid Roses which were grafted on some seedling Briers which were grown at Lyons. These Rose trees, which were growing in pots, had produced abundance of shoots from such roots as had touched the edges of the pots, and we even remarked some with a number of latent eyes on the collar below the graft, while on others there were shoots 1 ft. long, which had sprung from the collar by the side of the graft. It is, therefore, a mistake to suppose that by using seedlings we have in any way modified the inherent conditions of growth of the Brier, whose nature it is to reproduce itself by suckers which it throws off from all parts of its underground system, for we have only to divide the roots into pieces and place them in favourable conditions to obtain as many plants as there were pieces planted in the soil. In the month of March we take advantage of the fine weather to examine the grafts, prune down each shoot to within two eyes of the graft, and to take off all the ligatures. As for those subjects upon which the grafts have not been successful, we must cut down the shoots on the stem in order to promote the growth of fresh shoots, which may serve for the reception of fresh shield-buds. The other ordinary operations consist in placing training sticks, fixed to the tops of the Brier stocks, to serve as supports for the young shoots, which are tied to them with bast or rushes as soon as they are long enough, so as to protect them from the effects of the wind. While the young shoots are growing we must pinch down the shoots which spring from the two eyes left above the shield-grafts, as well as those growing on the sides of the stems, so that they may not draw away the sap from the grafts. Finally, when we desire that the shoots which have sprung from the stock should become sacrificed, we pinch them down to within about 5 in. of their base, but leaving the stumps which grow above the grafts until towards the months of August or September, that is to say, when they are ready for transplanting.

M. LACHAUME.

THE ROSE ANNUAL.

MR. WILLIAM PAUL'S Rose Annual for 1878-79 has just reached us, and fully equals its predecessors in point of interest. It contains coloured figures of Duchess of Bedford and Jean Liabaud (Hybrid Perpetuals) and of Madame Lambard and Souvenir de Madame Pernet (Teas). The letterpress treats of—1, the current year; 2, on new Roses; 3, on Rose stocks; 4, the Rose shows of 1873; 5, a mausoleum of Roses; 6, correspondence in reference to Roses. From these we select the following extract on new Roses.

Of the novelties of 1876-7 we named some of the best in last year's Annual. We now confirm that list, to which further experience enables us to add the following:—Hybrid Perpetuals—Duchesse d'Osuna, very bright and free in autumn, also distinct; Emily Laxton, Gabriel Tournier, very fine; Lady Mary Keith, Madame de Montchaudeau, Madame Devret, Madame Sophie Fropot, Monsieur Fillion, and Bourbon, Queen of Bedders. Coming down one year (1877-8), we find some really valuable novelties, of which the following seem the most promising. Hybrid Perpetuals—Dean of Windsor, Constantin Fretiaeff, Earl of Beaconsfield, Alfred K. Williams Boieldieu, Edouard Pynaert, Madame Jeanne Bonier, Madame de Laboulaye, Madame Gabriel Luizet, Madame Louis Donadine, May Quennell, Mrs. Laxton, Penelope Mayo, Red Dragon, Rosy Morn, Souvenir d'Adolphe Thiers. Tea-scented—Madame Alexandre Bernaix, Madame Lambard, Madame Maurice Kuppenheim.

The announcements from France this autumn are sufficiently numerous. One cultivator, Nabonnand, offers no fewer than thirteen novelties, and another, Eugène Verdier, ten, for which he asks 30 fr. each. This does not look as if the French growers had lost confidence in their new Roses, whatever the English growers may think on the subject. The following is an alphabetical list of the principal new French Roses of 1878-9.

1. ALPHONSE KARR—Tea-scented—(Nabonnand).—Growth vigorous; flowers large and full; colour purple, shaded with crimson, centres brighter. A seedling from Duchess of Edinburgh.
2. BARTHELEMY LEVET—H. P.—(Levet).—Growth moderate; flowers large and full; colour bright rose.
3. CLAUDE BERNARD—H. P.—(Liabaud).—Growth very vigorous; flowers large, full, and globular; colour deep rose. A seedling from Jules Margotin.

4. **DEUIL DU COLONEL DENFERT**—H. P.—(Margottin père).—Growth very vigorous; flowers large and full; colour velvety purplish black; one of the darkest of this section.

5. **DOCTEUR BAILLON**—H. P.—(Margottin père).—Growth very vigorous; flowers large and full, and very finely shaped; colour bright crimson, shaded with purple.

6. **DOCTEUR BERTHET**—Tea-scented.—(Pernet).—Growth vigorous; flowers large and full, opening well; colour pale rose, brighter at the centre.

7. **DOCTEUR JENNER**—H. P.—(Margottin père).—Growth vigorous; flowers large and full, with finely-rounded petals; colour carmine-red.

8. **FRANCOIS GAULAIN**—H. P.—(Schwartz).—Growth very vigorous; wood smooth; flowers large and full; colour claret red; one of the deepest-coloured Roses known.

9. **GASTON LEVEQUE**—H. P.—(Lévêque et Fils).—Growth vigorous; flowers very large and full; colour brilliant crimson, shaded with vermillion and fiery red; one of the freest and most perpetual-flowering varieties amongst the Hybrid Perpetuals.

10. **HENRI VILMORIN**—H. P.—(Lévêque et Fils).—Growth very vigorous; foliage ample and showy; flowers large and full, and of exquisite semi-globular form; colour red, shaded with purple and vermillion.

11. **INNOCENTE PIROLA**—Tea-scented.—(Ducher).—Growth very vigorous; flowers very large and full with large elongated buds; colour pure white, sometimes tinted with rose; said to be as fine a flower as Niphetos, and a better grower.

12. **JOHN SAUL**—H. P.—(Ducher).—Growth very vigorous; flowers very large, full, and globular; colour clear red, the back of the petals shaded with carmine. A seedling from Antoine Ducher, and a fine autumnal bloomer.

13. **JULES CHRETIEN**—H. P.—(Schwartz).—Growth very vigorous; flowers very large and full; colour deep bright red, shaded with purple. This Rose has proved a good autumnal bloomer, and has been awarded two bronze medals.

14. **MADAME AUGUSTE PERRIN**—Noisette Perpetual.—(Schwartz).—Growth vigorous; flowers of medium size, full; colour beautiful pale rose, the reverse of the petals whitish. Silver medal at Lyons Rose Show, 1878.

15. **MADAME CHARLES MEURICE**—H. P.—(Lévêque et Fils).—Growth very vigorous; flowers large and full; colour velvety blackish-red, shaded with purple.

16. **MADAME ETIENNE LEVET**—Hybrid Tea.—(Levet).—Growth vigorous; flowers large and full; colour cherry red, shaded with coppery-yellow.

17. **MADAME EUGENE CHAMBEYRAN**—H. P.—(Gonod).—Growth vigorous; wood smooth; flowers large, full, and globular; colour pale rose, shaded with salmon-rose. A seedling from Victor Verdier; a good autumnal bloomer.

18. **MADAME EUGENE VERDIER**—H. P.—(E. Verdier).—Growth vigorous; flowers extra large, full, and with very large petals; colour bright satiny rose, shaded with silvery rose.

19. **MADAME LILIENTHAL**—H. P.—(Liabaud).—Growth very vigorous; flowers large, full and cupped; colour bright rose, reflexed with salmon-rose.

20. **MADAME MORANE JEUNE**—H. P.—(Jamain).—Growth vigorous; flowers large, full, and cupped; colour satin rose, brighter in the centre, and the backs of the petals silvery. Beautiful in bud, and a good autumnal bloomer.

21. **MDLLE. BRIGITTE VIOLETT**—Hybrid Tea.—(Levet).—Growth vigorous; flowers large and full, produced in clusters; bright rose, slightly tinted with violet.

22. **MDLLE. LYDIA MARTY**—H. P.—(Liabaud).—Growth very vigorous; flowers of medium size, full; colour rosy flesh, shaded with lilac.

23. **MONSIEUR LAPIERRE**—H. P.—(Gonod).—Growth vigorous; flowers of medium size and finely shaped; colour shining red, shaded with velvety-crimson. A seedling from *Géant des Batailles*.

24. **PANACHEE D'ANGERS**—H. P.—(Moreau-Robert).—Growth very vigorous; flowers of medium size, full; colour pale rose, finely striped and marbled with purple and deep violet.

25. **PIERRE CAROT**—H. P.—(Levet).—Growth vigorous; flowers of medium size, full, and finely formed; colour deep red, changing to bright clear red.

26. **PREFET LIMBOURG**—H. P.—(Margottin fils).—Flowers large, full, and finely formed; colour dark velvety red, shaded with violet. A good bloomer in summer and autumn.

27. **PRINCESSE MARIE DOLGOROUKY**—H. P.—(Gonod).—Growth very vigorous; flowers very large, cupped, and finely formed; colour bright satin rose, very often striped with carmine. A seedling from Anna de Diesbach.

28. **REINE MARIE HENRIETTE**—Tea.—(Levet).—A red Gloire de Dijon of climbing habit, and with large and full flowers; named, by permission, after Her Majesty the Queen of the Belgians.

29. **SOUVENIR DE LAFFAY**—H. P.—(E. Verdier).—Growth very vigorous; flowers of medium size, very full, and of fine shape, produced in clusters; colour bright crimson, shaded with purple, and with fiery red centres.

30. **SOUVENIR DE VICTOR VERDIER**—H. P.—(E. Verdier).—Growth vigorous; flowers large and full; colour bright scarlet, shaded with purple and crimson. A good autumnal bloomer.

31. **WILHELM KOELLE**—H. P.—(Pernet).—Growth vigorous; flowers very large, double, and globular; colour very bright red. A seedling from Alfred Colomb; of good habit, and flowering freely till late in the autumn.

32. **WILLIAM ALLEN RICHARDSON**—Noisette.—(Ducher).—Growth very vigorous; flowers large and full; colour fine orange-yellow.

Of my own introductions, Countess of Rosebery, Duchess of Bedford, and Souvenir de R. Dudley Baxter, it does not become me to speak, their merits have been fully recognised by the horticultural Press. We also saw exhibited and thought well of Dr. Sewell and Harrison Weir.

When to Prune Roses.—If we take the country collectively experience clearly proves that early pruning is anything but advisable, as when the shoots are made so early as to get injured by spring frosts, it has a serious effect upon their blooming; but where there is a large stock in favoured localities it may be desirable now to prune a few by which means, if they escape frost, the season's flowering will be extended by getting some blooms earlier than they otherwise would have been.—I. BAINES.

THE FROST AND THE THAW IN WALES.

So far the winter has been unusually severe for this part of the country. During the greater part of December we had nearly 20° of frost nightly, but for a few days before and after the new year a thaw came, and, as in Mr. Fish's case (p. 23), the frost does not seem to have been so disastrous as might have been expected. My opinion, however, as to the cause of this, differs from that of Mr. Fish. The thaw itself was sudden and complete, certainly the reverse of gradual. Neither do I think the hoar frost kept the plants warm, but I am strongly inclined to think that the hot weather of last summer had rendered the frost powerless. I never remember seeing the wood of all kinds of trees and shrubs better ripened than it was last autumn. This was not only the case with fruit trees, but also with most tender shrubs, such as Myrtles, Hydrangeas, Camellias, &c. Not one of these has been protected, and yet they look as fresh now as they did in October. Two plants of the American Aloe have proved quite hardy on the top of two pillars where they stood all last summer fully exposed to the sun, but the other two behind a wall, quite hid from the sun, are killed. Broccoli behind a north wall are useless, while those in open quarters are as fresh as ever. Young Canliflowers, raised and left on a fully exposed south border, look as well as ever I saw them in frames at this time of year. Others, raised in a sheltered spot, have all but disappeared, and in all directions I observe that where every kind of plant was most exposed the frost has had least effect. I believe that had a sunless, wet summer preceded such a severe winter, there would have been more damage done to vegetation than has ever been heard of. It is, I think, a great mistake to plant tender plants in sheltered spots, shelter often doing harm than good. CAMBRIAN.

The Late Frost in Ireland.—From December 2 until Christmas Day we registered in the aggregate 382° of frost, varying nightly from 10° to 28°, but reaching a climax on the nights of the 23rd and 24th. On the former night the thermometer fell down to zero, and on the latter (Christmas Eve) it indicated (about midnight) 2° below 0. On Christmas Day, however, a thaw set in, which is continuing. We had a depth (1 ft.) of snow lying on the ground, but we may, nevertheless, expect to see many vacant places in herbaceous borders, and also amongst tender shrubs.—S. K., *Templepatrick, Co. Antrim*.

The Late Frost.—It may interest some to know that on Christmas eve Negretti & Zambra's thermometers indicated.—No. 1, 1°; No. 2, zero; the latter was about 100 yards from the other.—J. LAING, *Stanstead Park Nursery, Forest Hill*.

FLOWER FORCING IN MARKET GARDENS.

AZALEAS.—The demand for Indian Azaleas just before Christmas is very great, and thousands of plants are yearly imported from Holland and Belgium for forcing into bloom at that time. They are, of course, grown in Holland in the open air, and after they have formed their flower-buds they are taken up and sent by shiploads to London. Florists here pot them and place them in heat at once, and bring them into bloom, for the quicker they are brought into bloom after being potted the more likely are they to prove remunerative, as, if left too long, the check they receive in transit and potting causes them to shed their blooms, often to a serious extent. Kinds with striped, red, white, and crimson flowers are generally the most abundant, and single plants often bear several distinct-coloured flowers. The different varieties are grafted on stocks of a free-growing kind, and are on stems 6 in. to 8 in. long. Neat little plants, 1 ft. to 1½ ft. high, laden with blooms (which, however, are usually much smaller than those produced on English-grown plants), sell readily at from 2s. 6d. to 5s. each in the market retail. The chief advantage of imported plants is that they are much earlier in coming into bloom than English-grown plants. Of late years, however, some nurserymen have raised their own Azaleas, and they find them to be of a much better constitution than imported plants, and, by growing them in quantity, they can sell them almost as cheap as if foreign plants had been bought. The stocks, which consist of a strong-growing, purple-flowered kind are struck from cuttings or raised from seed; they are kept in cool houses in 4-in. pots, and in summer and autumn they are grafted with the best market sorts, and kept rather close until a union is effected, when they are grown in an airy temperature, receive copious supplies of water at the roots, and in three or four years handsome plants are the result. Several growers devote large houses to specimen Azaleas for supplying cut blooms at Christmas and Easter, these being the seasons when they realise the best prices, and at these times they contrive to have as many plants in flower as possible. The old white variety is the chief kind grown, coloured flowers being little sought after in the market at these festive times. The American hardy Azaleas are not grown very largely for market on account of their flowers dropping so quickly after being cut, and their colours are not such as are generally sought after in the market. The improved *A. mollis* and its varieties have, however, better-formed and more wax-like flowers, which stand cutting much better, and these may probably be largely grown for the purpose when a good stock of them can be got. Among the most favoured kinds of Indian Azaleas for market purposes are the rose-coloured *Bernard André* and its white variety. These are single-flowered kinds, but of great decorative value; the habit of the plants is good, and the flowers, which are freely produced, last for a long time in good condition. The best double kinds are: *Narcissiflora*, very early and pure white; *Imbricata*, white, slightly flushed with pink; *Borsig*, large, very double, and of snowy whiteness; *A. Rollisoni*, a good double, red flowered Alpine variety, will, when plentiful, probably be largely grown for market, both for the sake of its flowers (which resemble in appearance those of a *Balsam*) and as a pot plant; it is perfectly hardy and very floriferous, dwarf in habit, and altogether a desirable species.

CAMELLIAS.—In the shape of plants, Camellias are not sold in the market in very large quantities. Now and then a few small plants, bearing some five or six buds or blossoms, may be seen, but the chief use of the Camellia is to

supply blooms during the winter months, and for this purpose its culture is both extensive and profitable. Where a house with a northern aspect can be assigned to Camellias, and they are planted out in good turfy loam, and otherwise properly attended to, the yield of bloom on established plants is immense. The great bulk of the small plants of Camellias sold in London are imported from Holland and Belgium. They usually arrive in autumn, when their bloom-buds are set, and these they sometimes throw off shortly after being in the hands of the florists. Imported plants, however, come into bloom early, and a few good blooms from each nearly pays for the purchase of the plants. Nearly every market grower who has a spare corner cultivates Camellias, and many of the indoor fruit growers plant them largely in late Vineries, which are capital places for them. Mr. Yeldham, of Hammersmith, has a lean-to Vinery some 250 ft. in length, the back border of which contains thirty-five fine specimens averaging from 12 ft. to 15 ft. high, and as much through. All blooms that are sufficiently advanced are cut on each market morning, and on some occasions as many as 320 dozen have been gathered at one time. In early Vineries Camellias will not succeed, but in late houses they thrive admirably, the Vines affording them shade during the summer, and yet not obstructing light from them during the winter, when they are opening their blossoms. The old Double White is the only variety grown in this house, but a few good specimens of red kinds may be found in other houses about the place. The chief points in the culture of the Camellia are good soil in which to grow, plenty of water at the roots, cleanliness from insects and black fungus, and, last, but not least, plenty of air when the bloom-buds are swelling. Camellias are always cut for market when about half expanded; they have no stalk attached to them, as the florists in the market wire them, and in this way the flower really lasts longer than it would do on its own stalk.

CYCLAMENS.—No plant probably has increased so much in public favour in so short a time as the Persian Cyclamen. For every plant seen in the market a few years ago from the time we write there are now a hundred. One of the most celebrated growers of Cyclamens is Mr. Smith, Ealing, who cultivates from 12,000 to 15,000 plants annually, and who has them in flower from autumn to spring. The seed is sometimes sown in autumn and sometimes in spring, as soon as gathered; but the autumn-sown plants, if grown under favourable conditions, make flowering plants the quickest—and, as a rule, they flower best. The seed is sown in pans or shallow boxes, placed on a bed of Cocoa-nut fibre in which there is a gentle bottom-heat. The soil is kept continually moist; and, to attain this object, some place Moss on the surface. In a month or six weeks the seeds germinate, and the boxes are then placed near the glass, still keeping them in a warm house. When the young plants have made bulbs they are pricked off into other boxes of light, rich soil, the next shift being singly into 4-in. pots, and finally into 5-in. or 6-in. ones. During summer they are grown in pits and frames out-of-doors, all the heat required being supplied by the sun. Plenty of heat, air, and moisture constitute the secret of success; and, when in bloom, the chief enemy to guard against is damp. Perhaps a more interesting display than Mr. Smith's plants make when in full bloom it would be difficult to find. They are kept in low span-roofed pits until they come into bloom, when they are removed into light, airy, span-roofed houses, and placed in beds 6 ft. wide on each side of the pathway, which runs along the centre. I have seen three or four houses 50 ft. long thus

occupied. The plants are flowered in 5-in. pots fifteen months from the time of sowing the seed, and sometimes the bulbs measure $2\frac{1}{2}$ in. in diameter, whereas a few years ago it took several years to produce such bulbs. The improvement in the quality of the flowers, too, is quite as great as that in the culture. We have now flowers of remarkable size, and varying in colour from the purest white to the deepest purple, and many of them are deliciously scented. This improvement has been brought about by those plants bearing the most perfectly-formed and best-coloured blooms being yearly selected and placed by themselves for seeding purposes, a way in which the strain is annually improved in quality. Some growers sow *Cyclamen* seed in January, and grow the plants on rapidly through the summer, to form flowering plants in 6-in. pots by the following August, only nine months elapsing from the time of sowing to that of blooming. C. W. S.

VIENNA.

PUBLIC gardening and planting now being recognised parts of city improvement, any worthy effort in that direction comes within the scope of *THE GARDEN*. Austria has been so unfortunate in recent wars, and is supposed to be in such difficulties financially, that its capital is not, at first sight, one in which great improvements would be carried on at present. And yet not in Paris itself is there greater evidence of healthy change. Indeed, in one respect it is far ahead of Paris, and that is in the building art. Though this is somewhat out of our province, it is, nevertheless, so distinct and superior in Vienna, that it would not be fair to the city to speak of its improvements without noticing the stately houses that border its new streets. Although many of its projected improvements are as yet unfinished—a dozen Pall Malls might be stolen from Vienna and not be much missed. The lover of progress loves to see anything supremely well done, and does not mind if his idols or favourites are dethroned through the victory. He may well be pleased to see that while all the world is very justly talking of Paris and her improvements, Vienna has been quietly beating her hollow as far as buildings are concerned. The poor, cold, zinc and slate roofs of Paris with their pigeon traps on the top are intolerable to the eye fresh from the noble repose, ample and well-lighted upper stories, and rich, low, roofs of even second-rate streets in Vienna. There is something dangerous to the progress of architecture in France, owing to the hard and fast rules which make the streets all alike—alike even in the meanness and narrowness of the houses. The new Continental hotel in Paris has been much talked of for the comfort and sumptuousness of its rooms and fittings; outside it looks like any common building in the Rue de Rivoli, no doubt owing to some rule preventing the architect making his house different from the others—surely one of the most silly rules ever submitted to by an intelligent people. Of course, it is possible to err in the other way, and allow a Hankey to erect a dreadful and over-topping pile right against our most precious public buildings; but a happy mean might be found of allowing as much artistic variety as possible, and only excluding ugliness. In Vienna, while the height in most of the streets is uniform, there is a pleasing variety of style. The great charm, however, is getting rid of the old, high, sloping roofs with their narrow rooms or dens. The upper story is as good as any other, and the roof is at so low an angle that it is not, as a rule, seen from the streets; and when it is seen, being of richly coloured tiles, it is very different from the

poor cold roofs of Paris and London. Our own feeble architects, who apparently try to console us so often for thin walls and poking rooms by turning the roof into a kind of slated cruet-stand, argue that their precipitous roofs of ugly slate are needed in our climate to throw off the wet. Now Vienna is as wet as London and has very much more snow, which often falls there to a depth of 2 ft. and lasts a considerable time; but the architects manage to make perfectly sound and dry roofs, low and very pleasing to the eye when seen. In the old part of the city steep roofs are seen with their many windows in the narrowing roof stories, so that this change, so desirable from a sanitary point of view, has been effected in a place where the steep sloping roof was at one time considered necessary. The public buildings are quite as remarkable as the private houses, there being five important ones now in course of erection, including a parliament house a hotel de ville and two museums.

The disposition of the streets, that correspond in importance to the frequented boulevards of Paris, is excellent, the Ring Strasse being about 150 ft. wide. This width allows of planting abundance of shade trees without interfering with the light or the appearance of the houses. In Paris the trees often interfere in both ways. In the large Vienna avenues there is a wide footway without trees on each side, then a roadway mostly for the use of the house and local traffic, then two lines of trees with a smooth wide footway between them, and then a large open road in the centre for tramway and general traffic. It will thus be seen that the space between the houses consists of three carriage ways and four ample footways and four lines of trees—these forming a shady avenue for pedestrians on each side of the great central roadway. The street planting is of the kind with which we are familiar in Paris.

The public gardening of Vienna is, as a rule, blighted by the influence of the "French" school—the old deadly school responsible for clipped gardens. Schönbrunn and the Augarten are large spaces, called gardens by courtesy, but which are really garden-tombs—wholly devoid of a single quality of a real garden. The good Botanic Garden in one retired corner of the Schönbrunn Sahara modifies somewhat its sad impression; but for unrelieved deadly formalism and gross stupidity of garden design, there is, perhaps, nothing in this world more dismal than the Augarten at Vienna—a noble piece of ground with enormous walls of clipped trees only and long weary walks. Looking up from these walls, a narrow strip of sky may be seen—no more. Between the high green walls there is a mass of attenuated scrub. The space is not only wasted itself, it is not only no garden, but it is so arranged that even the air (so liberal to the waste) cannot enter it freely; and there are no fine views which such an ample piece of ground might show of one of the noblest of cities. The much talked of Prater, a very large surface of ground, is the worst designed of any large park which we have ever seen—no breadth, no repose, no turf, no views, anywhere; even the main drive through it is poor and narrow. As regards the Prater, all has to be done, and if simply and wisely designed it would make a noble park. There is a small English garden and lake laid out in it by a Frenchman some years ago, but such is not the species of improvement required by a park of this character. A few bold and useful roads, wide, airy sweeps of turf, some shade where most required, and many groups and groves of hardy forest trees—the whole disposed by some one with a fine feeling for and knowledge of the elements that go to form the most beautiful scenes of natural sylvan beauty, are what would

make the Prater worthy of so noble a city. Numerous as are the costly stupidities in public gardens, in no other could there be found so poor in all that is essential to healthy pleasure or enjoyment as the Prater, Schönbrunn, and the Angarten. As for the smaller city gardens, they are formed on a different plan, and it is possible in them to see trees and flowers in their natural forms, and also some verdure and variety. One small park, called the Stadt Park, seemed the most interesting; it is well laid out, and has a great variety of trees and fine-foliaged plants and flowers. The most distinct feature in these gardens is the dotting of many plants on the Grass instead of in beds, though there are flower beds too. This is a good system where carried out with some taste and temperance, but one very likely to prove unsatisfactory where left to persons without a keen sense of what is best in such a plan. To succeed with it one should know how to secure great and bold variety while avoiding a mere accumulation of "dots;" should feel the need of keeping ample foreground and sufficient breadth; should hate repetition, and should have a delicate knowledge of grouping and placing the various objects, which could only be obtained from extensive acquaintance with plants both in gardens and in a wild state. That such hands were not the authors of much of the grouping here was but too clear; some subjects like Dahlias, of which one or two, or even three, groups or colonies would have looked charming and given character and variety, are repeated in some cases all over the place, so as to produce disagreeable monotony, while many kinds of plants of equal, or greater, importance are wholly absent. The ugliest things grouped in the above way are standard Roses, always offensive unless where the heads become so large and vigorous that one no longer notices that they are standards.

MELON-CUCUMBERS.

Of the immense variety of gourds and other Cucurbits in cultivation, few are known in a wild state, and there is little doubt that they are really the products of cultivation, and never existed

Varieties of Melon-Cucumbers Raised from Seeds of a Melon.

in a wild state. In fact, the same may be said of the varieties of most economic plants under cultivation. By some botanists, including Mr. C. Naudin, who has conducted a large number of experiments in hybridizing members of the Cucurbit family, it has been averred that it is not possible to effect a cross between a Cucumber and a Melon. On the other hand, several supposed hybrids between these two plants have been exhibited or described from time to time, though, perhaps, not one of them is beyond doubt. The three fruits, of which

sketches are herewith given, are the issue of a plant believed to be such a hybrid. The parent originated in Mr. Leclerc's garden at Eprenay. Mr. Leclerc communicated the history of it, together with seed, to Mr. Carrière, the editor of the "*Ravue Horticole*." In 1874 Mr. Leclerc bought a Cantaloup Melon at a fruiterer's in Eprenay, and, as it proved a very good one, some of the seed was saved and sown. The first sowing was made in 1876, and of twelve plants two produced fruit resembling Cucumbers. Thinking it was the result of some mistake on the part of the gardener, he had them uprooted before the fruit came to maturity. In the spring of 1877 another dozen plants were raised from the same seed, and Mr. Leclerc was very much surprised at the unusual length of the male flowers borne by three of them. One of these plants was sent to the Comte de Lambertye, and it bore three fruits. One of them was the shape of a hunting horn. It was cut before it was ripe, and it was of a woody consistence with an acid juice inside. The second was shaped like a large Cucumber, much swollen in the middle and at the tip. It was slightly curved, 53 centimetres long by 15 centimetres in its largest diameter. The flesh was pale yellow, slightly sugary, and had the flavour and odour of a Melon, with a decided after-taste of Cucumber. The third fruit was forwarded to Mr. Carrière, who communicated seeds of it to various distant friends with the request that they would cultivate some of them and watch the result. This fruit was very much curved and attenuated at the base, and 71 centimetres long by 10 centimetres in its greatest diameter, and weighed about 5 lb. The skin was smooth, or here and there very slightly rugose, thin, very delicate, and of a rather deep yellow when ripe. The flesh was yellowish-white, passing into pale red towards the centre of the fruit, quite melting, very juicy, and having a very decided flavour of Melon, though leaving a bitter after-taste in the mouth. Seeds of this were sent to various persons, among others to Messrs. Vilmorin, and the progeny varied considerably, as the illustrations show. The surface is more or less smooth or ribbed, greenish-yellow, passing into a butter-yellow when ripe, and the flesh relatively thin, and of the nature described above. Whether of hybrid origin, or the result of natural variation this is a very interesting phenomenon. One of the most singular facts connected with it was the production of normal and abnormal fruits from seeds out of the same fruit.

W. B. HEMSLEY.

Tomatoes.—I have just now a houseful of these which have been in full bearing since last July. They are growing, flowering, and setting just as freely as in the middle of summer. We use them occasionally for dessert; in fact, I find them to be a most useful addition to our winter supply of forced vegetables.—R. GILBERT.

The Negro French Bean.—I have been forcing this variety of French Bean for the first crop, and find that it produces at this dull cold time of the year larger pods than any I have yet tried. It likewise sets well. The next variety which I force as a succession to it is Osborn's Winter Forcing, another excellent sort for early forcing. With Canadian Wonder for the latest crop, a better selection than the above could not be made where a good supply is required during the winter and spring months.—WILLIAM TILBERRY, *Welbeck*.

Skeleton Leaves.—Three cases of "skeletonised" leaves were shown at South Kensington last summer by Mrs. Consons, of Southport, and the following note concerning them is given in the Society's journal just published:—"For the dissection of leaves I find the process of maceration too long and tedious, to say nothing of the uncertainty as to the results. I have therefore adopted the use of alkali in saturated solution, the specimens to be introduced while the liquid is heated to boiling point. The time of immersion to be regulated by the character of the various leaves, and the nature of the epidermis to be removed. When the specimen is freed from epidermis and cellular tissue, it must be subjected to the action of chlorine to destroy the colouring matter. The introduction of peroxide of hydrogen serves not only to render the lace-like specimen purer in colour, but preserves it also. In destroying the colouring matter of Ferns this is likewise invaluable; added to the chlorine it gives a solidity to the bleached fronds, and appears to equalise the action of the chlorine. For skeletonising capsules the slow process of maceration by steeping in rain water is alone available—a moderate heat may be applied to hasten the process, but alkali is useless. Skeletonised leaves and capsules appear to gain in the process a toughness and durability not possessed by them in their natural state."

PROPAGATING.

CONDITIONS UNDER WHICH GRAFTING IS BENEFICIAL.

We sometimes think that these are not so general as may be imagined. In fact, if it be true, as physiologists tell us and cultivators believe from practical experience, that a reciprocal action exists between the root and top of a plant—that the one is pretty much what the other makes it—then it follows that if we graft a weak-growing Vine, for example, upon a vigorous stock, and only permit the development of leaves and branches on the scion, the stock must eventually lose its superior vigour to a great extent, if not wholly, and the Vine will be no better off than if it had been on its own roots. Perhaps a little may be allowed when the stock, in addition to being more vigorous, is also of a harder constitution. And, so far as I have observed, this is exactly what happens in the case of grafted subjects. Under equal conditions a Black Hamburgh Vine makes better roots, and more of them, than a Black Hamburgh stock that carries a top of some weak-growing Vine only, and this when both roots and stems were equal to begin with. Neither does the girth of stem of the two increase at the same rate, but the Hamburgh thickens faster than the grafted scion. This is a more important question than at first appears, for it affects the whole question of budding and grafting. Some years ago, it being supposed that a certain new Vine (the Muscat Hamburgh) succeeded best when grafted on the Black Hamburgh, nurserymen laid hold of the idea, and plants were advertised guaranteed to be worked on the Hamburgh stock at the outset. Seemingly, however, the plan did not lead to any great results, for it was not long heard of. Let me here state that I am not now speaking of grafting with a view to check the vigour of the top, as is the object in the case of the Quince stock, but the reverse. Practically I have not turned my ideas on this subject to much account, except in the case of Vines, and I am not the only one who has noticed the fact in regard to these during the last two years; but it is now more than ten years since I gave up the practice of employing strong-growing Vines simply as stocks for weaker sorts. On the contrary, in order to get the full benefit of the stock employed, I have allowed it to produce fruiting limbs as well, and have made the grafted sort only one limb of the tree; but mostly we have grafted the Vine half-way up the rafter, the bottom portions bearing the fruit and leaves of the stock, and the top the grafted Vine, thus preserving the native vigour of the stock by its own growth and foliage, and imparting the same to the grafted portion. And it seems to me this is the only way to get the full benefit of grafting. It may be that a stock wholly deprived of its own foliage may never entirely lose its inherent vigour and vitality by being made to carry a top of a naturally less vigorous habit; but facts go to show that it is at least greatly enfeebled.

I have chosen the Vine to illustrate my meaning clearly; but, as I said before, it is a question affecting other budded or grafted subjects as well, and particularly Roses. We have rather extensive plantations of Roses here, which have been added to and made up at intervals during the last fourteen years, and nothing has struck me more than the comparative growth of the Brier stocks on which the different varieties are worked. Our soil is naturally a Brier soil, and we have many whole, half, and quarter standards on that stock, and have been able to note the effects of the growth of the Roses upon the thickening of the Brier and the production of roots, and my observations bear out in a very remarkable manner what I have stated in regard to the Vine. Roses which years ago were received with Brier stems all of the same thickness, being newly budded, of course, have altered very much since then. Brier stems on which strong-growing varieties of the Rose were worked have been much increased in girth, and produced plenty of roots, while the stems of weak-growing sorts have made proportionately less progress and correspondingly few roots. Some sorts, indeed, that do not appear to thrive in our cold and exposed situation, have not thickened perceptibly in the stock: all, nor made any roots worth mentioning. We have lately gone over our plantations, and planted 200 fresh plants in place of poorly-growing sorts and to make up blanks, and I have been particularly struck with the facts I have stated, and which I have doubt can be corroborated by other Rose growers. In short, wherever we have a strong-growing kind of Rose—like Gloire de Dijon, for example—we have a strong Brier stock and plenty of roots, and *vice versa*, thus showing that the stock is completely under the control of the top, whatever may be its character. Such facts lead one to doubt Dr. Lindley's dictum that "species which are naturally delicate become robust when 'worked' on robust stocks," when, at least, the growth of the scion only is permitted. Indeed, the doctor's own teachings on the subject of vegetable physiology prove such an hypothesis to be wrong.

If the views I have expressed be correct, then some of the pruning and other cultural practices at present followed must be wrong. For instance, in the case of the Rose, when suckers from the Brier stock push below the graft, we call them "robbers," and always rub them off as a matter of course; but do such growths really do harm, and might they not be advantageously encouraged in some cases? I put this question to Rose growers and others experienced in such matters, as I think the question is well worth considering. My own opinion is, that a moderate encouragement of growth from the stock, as near the graft as possible, would encourage a weakly Rose or feeble-growing variety to increase its vigour and improve its flowers; or perhaps the same might be gained in a better way by budding vigorous and weak-growing Roses on the same stock. I am aware the generally accepted opinion is, that the stronger growth robs the weaker one; that was my own opinion once, and I am prepared to admit that in some cases such an opinion may be correct; but, as a rule, I believe a weak or feeble-growing branch is encouraged, and, to a certain extent, upheld by the stronger one when the latter happens to be near it, or on the same leading trunk. In other words, we do not improve the chances of a weak or sickly limb by cutting away all the stronger growths in order to divert the vigour and sap into the weak one, but which is a very common practice; the strong branch keeps up the vitality and the circulation, and the weak one shares in it. This is distinctly exemplified in the case of variegated plants, upon which we have tried the experiment purposely years ago, and always with the same results. Some plants, like the *Cyperus alternifolius variegatus*, *Alcascia macrorrhiza*, *Alyssum variegatum*, *Mangles' Variegated* and *Flower of the Day Pelargonium*, &c., frequently sport to the pure white form, producing whole limbs and leaves without a speck of green upon them, and which grow as freely as the healthy green parts of the plants while the latter remain; but cut the green leaves and shoots away, and the white limbs perish in a very short time, thus showing that their very existence depended upon the welfare of the healthy branches. I apprehend that a similar sympathy exists between a weak branch or a strong one, as in the case of the rose and other plants. In short, the fact appears to me to be indisputable, that when we graft a plant upon a foreign stock, and the scion only is permitted to grow, the stock, after it has lost the inherent vigour it brought with it at the beginning, becomes little more than a channel of communication between the top and the soil, depending quite as much upon the scion for its existence as the scion does upon it, or more.—"Field."

Propagating Oaks.—In making a few remarks on the fine quality of Acorns which I saw the other day in a nursery, and which had come from the south of England, I was told by the nurseryman that seed from the south, and especially from France, was preferred, as it invariably produced the finest and largest plants. The Acorns gathered in this part of Yorkshire, he said, produced plants about 9 in. high, while those produced from seed from the south of England were as strong again, and those from the French seed still stronger. The fact is perhaps familiar to nurserymen, but it has an interest for gardeners as well. The question is, is it the size of the kernels or their more perfect maturity that is productive of the extra vigour, and are the results permanent? Is the difference in growth noticeable after the first year or two? If it be due to the size of the seed, one would think the difference would not be lasting; but if due to more perfect maturity, it might. I am inclined to think that bulk of seed has more to do with it than ripeness. About here Acorns ripen well and vegetate freely, but they are from one-half to two-thirds smaller than those which come from the south. In garden culture I am not prepared to say that large seeds produce the best or most fruitful plants; but there can be no doubt that the best-ripened seeds do, a fact which is pretty well illustrated in the case of the Melon and Cucumber for example, and Beans and Peas, &c. Not only do they vegetate more readily and surely, but the vigour of the plants is much greater. It is not to be inferred, however, that partially immature seeds are incapable of producing plants. The chief difficulty with these is that they do not vegetate freely; but, when they once begin to grow, any leaf which they make adds to the prospect of their becoming healthy plants, as they then begin to make roots on their own account, and soon become independent of the support derived from the seed. I have often nursed weak Melon plants, from poor or ill-ripened seeds, into good, healthy specimens by extra care, when I had little more than two very imperfectly-developed seed leaves with which to work. By keeping them near the glass, and in a comfortable temperature, the pale and sickly leaves get greener and stouter day by day, and when the first rough leaf is made they are out of danger. This care is not often necessary, of course, but I have had to practise it now and then in the case of new sorts.—J. S. W.

FOOD-BOXES FOR OUR GARDEN SONGSTERS.

DURING the inclement weather which preceded Christmas Day, lamentable accounts were heard of the great mortality amongst small birds, especially in the north of England; and the well-known ornithologist, M. O. Morris, and others appealed to all lovers of the feathered tribe to repay the debt owing for many a sweet song by throwing the half-starved minstrels every day a handful of crumbs. The latter, it was pointed out, should always be strewn about on the same spot, and, by preference, among the bushes. If, however, the winter is a severe one, the crumbs may be speedily hidden by a fall of snow, and the work of clearing the feeding-ground will have to be repeated again and again. To save this trouble, and make sure that the birds are able to partake of the repast offered them, Mr. Brunzel, of Breslau, recommends the use of a food-box employed by the Vienna Animals' Protection Society, and represented by the annexed woodcut. The special feature of the box is that its open end always turns to the opposite direction from which the wind and snow are coming. The food is thus naturally protected against the latter, and the birds find shelter from the cold. With respect to the construction of the apparatus, the box and two wings (intended to act as sails) may be made of $\frac{3}{4}$ in. deal boards; the back, to allow the crumbs to be seen better, should consist of glass, and the top or roof, projecting a little beyond the sides, slant down to it. The position which the box ought to occupy when placed on the spindle attached to the upper end of the support is indicated in the engraving, and, as regards height from the ground, this will vary, according to the situation, from 3 ft. to 5 ft. or more. If, as is desirable, the box receive two or three coats of paint, all

Food-box for Birds.

bright colours must be avoided, and, on account of its gloss, of course, no varnish should be put on. A greyish or dull green is, perhaps, the best colour. T. S.

REMARKABLE OAK GALL.

THE various galls on plants caused by insects, especially by those of the family Cynipidae, have much interested naturalists and others, varying as they do so much in form and structure, and often assuming very attractive and curious shapes, as in the Bedeguar of the Rose, and several of the galls on the Oak. Among the most remarkable with which I am acquainted is the gall that I am about to describe, which has recently been brought to my notice. It is produced on the cup of the acorn of an Oak. Referring to the annexed figures, which are drawn somewhat larger than nature, one giving a front view and the other a side view of the gall, it will be seen that a series of elongated, rather flattened and pointed, slightly curved lobes, go forward from a point on the outside of the acorn cup, and spreading right and left clasp the cup and the acorn so as to leave but a small portion of either exposed to view. The gall appears in the specimens which I have examined to spread very regularly on each side of the point from which it springs, and to form lobes corresponding to each other in size and shape, giving the whole one uniform character. The substance of the gall is internally hard and

somewhat corky, and when dry of a dull, yellow-ochre colour, which is also the prevailing colour of the whole gall. Externally the surface is either rugose and pitted, or in places smooth and leather-like. One specimen of the gall entirely covered both the cup and acorn, so that only the apex was visible. A specimen which I broke open had a large, elongated, hollow chamber, smooth inside, in one of the larger lobes, in which was the cocoon of an insect of a very regular, oval shape, $\frac{1}{4}$ in. long, and about $\frac{1}{8}$ in. in diameter. This cocoon had a hard, even case of the same colour as that of

Oak Galls.

the gall. I have tried to find specimens corresponding with this gall in the metropolitan collections, but have failed, except it be one in the British Museum which much resembles it. It is there called the gall of *Cynips calicis*. This gall is probably referred to in Rothschild's "Insects" (fig. 211, vol. III), where, at the end of the article *Cynips*, he says, "Another species, the *Cynips calicis*, pierces the calyx of the young acorns, the deformed fruit of which develops into leaves super-imposed on each other and curled up," and there is in the "Entomologist" for August, 1878, p. 182, a gall figured under the same name which has so much in character with the gall here figured that I have every reason to think that both have the same origin and are produced by *Cynips calicis* (Burgsdorff).

Worthing.

W. W. S.

A PEEP INTO A PARIS FLOWER SHOP ON ALL SAINTS' EVE.

On a dull, wet evening (Oct. 31st, last year) I wandered into a flower shop not far from the Madeleine, my friend H., an enthusiast about flowers, wanting to purchase a Tree Carnation which had attracted his notice the day before. H., with the caution of a true Englishman, is of opinion that foreigners, Parisians in particular, invariably ask nearly double the proper price for their wares, and that it is a duty to himself and his travelling countrymen to beat down these shopkeepers to what he thinks the right sum. Although he speaks of this as a stern duty, I think it is not an unpleasant one, and that he rather enjoys the process. The little shop itself was quite a picture; it was a bower of Palms, Ferns, and plants in bloom. Pots of white Lilac, Roses, Pinks, and Carnations, shed a delightful perfume. Two or three girls were occupied in making bouquets and garlands, while the presiding deity, a stout, middle-aged woman, with a good-natured face, waited on customers, at the same time superintending the workers. While H. was bargaining with her for his Carnation, I watched the packing of a large box, which contained a cross, a wreath, and a cushion of flowers. The last, about 8 in. long and 6 in. wide, was composed of double Neapolitan Violets, with here and there a white Rose bud. The cross, which was about 2 ft. long, was made of white Roses and Carnations, with a delicate edging of Myrtle sprigs; the wreath was of the same flowers, mixed with knots of Violets. The packer was placing these most carefully in a deep box, and arranging them with thin lathes, so that they were perfectly firm and did not touch each other. "What are you going to do with these lovely flowers?" I inquired. "Monsieur, they are to be sent off to Rheims to-night to Madame de F. We received particular orders that they should be there early to-morrow morning. She lost an only daughter about this time last year; she was but 18, and we were to make the cross and wreath of white

blooms, but these Violets were so fine that we thought a few bunches could not be amiss. What does Monsieur think? "*Allez vite Nicole, tu seras en retard*," anxiously exclaimed the mistress, who had been bestowing a somewhat divided attention on H.'s wants. "The price," said she, turning to me, "of the wreath, cross, and cushion, is 75 francs. Are they not lovely?" I answered truly that I had never seen any arrangement of flowers before which pleased me so much. "These," continued she, "will be placed on the grave of Mdlle. de F. early to-morrow; perhaps Monsieur, though an Englishman, will remember that we decorate our graves for the Toussaint! We have been sending out wreaths and crosses all day, but none so lovely as these." I could not help remembering the burial scene in *Cymbeline*, when the two brothers are bearing the disguised Imogen to her rest. (It is always a relief to my mind to know that she is not really dead, though this somewhat interferes with the pathos of the lines):—

With fairest flowers,
Whilst summer lasts, and I live here,
I'll sweeten this sad grave: Fidele, thou shalt not lack
The flower that's like thy face, pale Primrose, nor
The azure Harebell, like thy veins; no, nor
The leaf of Eglantine.
Yea! and farred Moss besides, when flowers are none,
To winter ground thy corpse.

W. N.

ANSWERS TO CORRESPONDENTS.

Mysiphyllum asparagoides.—I should be much obliged if you would give me directions as to the treatment of *Mysiphyllum asparagoides*, and at what heat it should be kept?—S. W. C. [It should be grown in an intermediate house in a temperature of, say from 55° to 60°, and its shoots should be allowed to twine themselves up pieces of string, or netting strained closely under the glass. It succeeds best in a well-drained soil consisting of turfy loam or peat, or both, with the addition of a little sand and decayed leaf mould or manure.—S.]

Cypripedium spectabile.—How can I best succeed in growing this handsome Lady's Slipper?—H. C. [Plant it in a moist but well-drained, sandy soil in a sheltered position, or you might grow it in pots or pins in the greenhouse, in which case use good fibrous loam, leaf mould, and sand, and let the pots be well drained.—S.]

Early Melons.—As a rule every gardener has a favourite Melon of his own, but "J. W." (p. 24) may place every confidence as regards obtaining an early crop of Melons in Gilbert's Improved Victory of Bath (green fleshed) and Williams' Paradise Gem (scarlet fleshed). Both force well, set freely, and are excellent in quality. For a second crop in a hotbed frame Golden Queen (green fleshed) and Read's Hybrid (scarlet fleshed) are equally good.—J. SMITH, *Waterdale*.

—"J. W." (p. 24) should grow Sutton's Hero of Bath as an early scarlet-fleshed kind—it is first-class in all points; and, for an early green fleshed variety, there is nothing better than Heckfield Hybrid which that variety can be obtained true. For frame culture Hero of Bath and the old Egyptian (green flesh) are suitable kinds.—H. W.

—Let me recommend "J. W." (p. 24) to grow Eastnor Castle and Read's Scarlet Melons both for his pit and frame crop. We have grown many varieties, but have found none better than these, all things considered.—CAMBRIAN.

Plants for Carpeting Bulb Beds.—The following list of plants named in order of merit will answer "J. S.'s" purpose (p. 24) admirably, viz., *Sedum glaucum*, grey; *S. lydium*, green; *S. acre elegans*, pale yellow; *Saxifraga rosularis*, silvery-white; *S. hirta*, green; *Antennaria tomentosa*, white; and *Herniaria glabra*, green. All are surface rooters, and look equally well in summer and winter.—W. W.

Smuts from Furnaces Chimneys.—"A. E." (p. 24) would find coke more economical than coal, and much the best way of getting rid of the smut nuisance of which he complains.—W. W. H.

Aster-growing for Market.—How do market gardeners grow Asters so as to send them to market in bloom in pots?—H. H. C. [They sow the seed in heat in spring, harden off the young plants when up, and plant them out, after all danger from frost is over, in rich ground in an open situation, mulching the ground in hot weather to keep it moist; then, when wanted for market, they are lifted and potted.—S.]

Fungi in Mushroom Beds.—The fungi growing in the centre of "T. S.'s" Mushroom bed belong to *Agaricus virgineus*, a common occupant of Mushroom beds. The explanation of your case is simple. The unwelcome fungus delights in half-decayed manure equally well with the Mushroom itself. As the spores of the first are commonly floating in the air, whenever they happen to light on a well-prepared Mushroom bed they are sure to grow. Such cises are common, and we have frequently known the Mushrooms to be completely ousted by the new comers.

Nettles Under Trees.—Nettles soon succumb to repeated cutting down of their tops, or a still more effectual way of dealing with them is to dig the ground which they occupy, in winter. It need not be turned over very deeply, and the few that will sprout up in the ensuing spring can be easily destroyed with a hoe or fork. Of all the plants of a peren-

nial character which come under the denomination of weeds, I do not recollect one less difficult to eradicate than Nettles, a fact easily accounted for by their being much more impatient of disturbance at the root than plants of a like description. On open ground there is absolutely no difficulty with them. I once had a dense bed occupying a considerable space simply dug over, not trenched, with a little manure previously spread on the surface and worked in as the ground was turned over. It was planted with Potatoes in the beginning of April and produced one of the best crops I ever saw, the roots of the Nettles decaying being just the shrouns sort of material in which Potatoes luxuriate. All who have plenty of luxuriant Nettles may rest satisfied that they have some good land. The common British species (*Urtica dioica*) wherever I have seen it has invariably been located on good soil.—T. BAINES.

Baits for Field Mice.—Allow me to assure Mr. Harpur Crewe (p. 24) that I am not too comprehensive when I add the short-tailed field mouse to the kinds which I have succeeded in capturing with nut kernels. A year ago I was annoyed by having the fruit of *Psidium Cattleianum* and *Eugenia Ugni* under glass carried off as fast as it ripened. I set my traps, the falling kind, the best I think ever invented, and secured the delinquents; they proved to be a pair with short tails. This species in severe weather feeds on the smooth bark of trees. Last winter I had a large *Jasminum revolutum* destroyed, through their devouring the bark from the collar upwards 18 in., and I noticed during the late severe frost that they were attacking some large plants of *Aralia Sieboldi*. They will also, I believe, mount the highest Apple and Pear trees in order to get at the best fruit. By the way, I fancy bank vole is a misnomer, as, if I am not mistaken, it always makes its nest like the open fields, selecting a dry spot in which to burrow, and from which, beneath the herbage, its run ramifies right and left, frequently extending long distances. I quite agree with Mr. Crewe's remarks about owls and should like to see his wish become the law of the land. They are the farmers' and gardeners' best friends, but are regarded generally as their direct foes. I have several here and value them as ornithological treasures, far above the game, but I find it difficult to protect them from the prejudiced around me.—J. M., *Charmouth, Dorset*.

Treatment of Tuberous-rooted Tropæolums.—There should be no difficulty in inducing these Tropæolums to flower. If your correspondent's plants are now growing freely they will soon be showing their bloom buds. They should stand in a light, airy position in a cool house, or in the window of an apartment where a fire is not continually maintained, and where air can be admitted in favourable weather. If grown in heat or in confined quarters, they seldom flower satisfactorily. During the next two months water should only be given when the soil is quite dry, but when fully established and coming into flower, they will, in warm weather, need copious moistenings. When in bloom, shade them from the hot sun and sprinkle the path and stage, which will have the effect of prolonging the blooming season. Generally speaking, if a plant be troublesome, and if not promptly exterminated, it will turn the foliage yellow and completely paralyse the growth.—J. CORNHILL, *Bijlzet*.

Names of Plants.—*Anon.*—We are unable to satisfactorily identify the leaf, but probably with more material, such as a flower, it would be an easy matter.

Questions.

Pine-apples.—What is the best structure in which to grow Pines? And what is the best material in which to plunge them? Also, what is the best soil for Pines where no proper loam can be procured?—A GARDENER.

Rheum officinale (Baillon).—Will some one of your correspondents who have access to the best authorities kindly point out the differences, if any exist, between this plant and the so-called *R. palmatum* tangutensis? The one is not without importance for medicinal purposes, and in one trade list from an eminent firm the two plants are offered as distinct and at very different prices. In another catalogue, from a house equally reputable, they are offered as synonymous. Which is right?—W. T. I.

The Short-tailed Field Mouse.—We used to have here several establishments of the barn owl which were carefully preserved, but, for some unexplained reason, they have left us, or been shot in their foraging expeditions in the neighbourhood. Since the disappearance of the owls my rock garden has suffered severely from the ravages of both the long and short tailed field mouse, especially the latter, which now swarms here, and which we find most difficult to trap. Not content with the *Cistus*, dwarf *Genistas*, and other low-growing plants, it has cut off the Japanese Honeysuckles down to the ground and done a great deal of damage. The barn owl is invaluable as a destroyer of mice, and is the natural provision made for curtailing the numbers of these mischievous little animals. I entirely agree with Mr. Harpur Crewe, and think every man who kills a barn owl ought either to be fined or otherwise punished. The most casual observation would convince any one of the services rendered to man by this harmless and useful bird.—ALFRED ELLIS, *The Brand, Loughborough*.

A Substitute for Holly Berries.—We have not had a single Holly berry during the whole of the late festive season, but we have several large red-berried *Solanum* plants covered with fruit which we have cut freely, and the small branches, when mixed with evergreens in wreaths, &c., have an excellent effect.—CAMBRIAN.

[Vol. XV.]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE SOILS AND ROSE STOCKS.

"If I had only a good Rose soil, I have no doubt I could grow good Roses," is an exclamation one often hears from those who have been unsuccessful in their culture; but it is a mistake to suppose that such a soil is absolutely necessary even for those who grow for exhibition, for one of our most successful amateurs has only a light sandy soil, and yet he can produce flowers which gain for him silver cups and prizes; at the same time, it must be confessed that a good soil is a great help to good Rose growing. The rich, unctuous loam of Hertfordshire and Hereford, of Slough and Colchester are just the soils in which the Rose delights; but it is accommodating, as the luxuriance with which it grows in many a cottage garden, diffusing its fragrance all around, testifies, while, as we know, the wild Rose throws up its vigorous shoots in all soils and in all situations. One sees it on the shores of a Scottish loch, resting deep in the moist peat; on the wild moorlands of Ireland, in thin, gravelly soil; or in the rich hedge-grows of our English counties, in deep, loamy soil; and although in all it seems to flourish, yet it is in the latter that it is especially at home. Hence, no one need be discouraged at the thought that their unsuitable soil prevents them indulging in their love for the Rose. Bearing in mind, then, the character of the soil it especially likes, we must endeavour to remedy any defect so as to approximate to it. Where soil is light and rich, loam or even clay must be added to make it more tenacious. My own garden is of that character—a rich, alluvial soil, in which well-nigh everything will flourish; but the Rose does not like it, and hence I am obliged, with some considerable difficulty to get loam from a distance to add to it. Where soil is too stiff (not very often the case) it may be made lighter by the addition of ashes, as well as manure; but the chief difficulty is with light, not heavy soils. I need not insist upon thorough drainage where the soil is very heavy; stagnant water about the roots is death to the Rose; for although it will bear a great deal of moisture, it will not tolerate insufficient drainage. Many of our older varieties of Roses may be had on their own roots, and there is no doubt that thus they flourish best; the Moss, Cabbage, Gallica, and other summer-flowering Roses are all better as dwarf, compact bushes, but it is a different matter when we have to deal with the Teas and Hybrid Perpetuals. In the southern parts of England the Teas do well out-of-doors, and will stand the winter with but little protection, but in the colder parts of the island this is impossible. The Hybrid Perpetuals, having the blood of various races in them, are some of them more tender than others; and although they are in some instances grown on their own roots, yet in perhaps 99 cases out of 100 they are grown as budded plants, and the question has been hotly debated, Which is the best stock to use? A great impulse was given to Rose growing by the introduction by the late Mr. Rivers, about forty years ago, of the Manetti Rose from Italy, and for thirty years it has held almost undisputed sway as a stock for dwarf Roses. Standards are still grown, and, as far as one can see, must be grown on the Dog Rose. Thus, one large Rose grower is said to bud 250,000 Manettis every year, while of 12 acres grown by another more than 11 acres are under the Manettii. Of late years, however, a reaction has set in, or rather, let me say, a fresh candidate for favour has arisen in the seedling Brier, long used by the French Rose growers as a stock for their Tea Roses, but of late years brought prominently into notice by Mr. Prince, of Oxford, who grows it exclusively, and uses it for Rose of all descriptions. It has rapidly come into favour, while cuttings of the Dog Rose are used by other cultivators, the fact being realised by both that the Dog Rose has its disadvantage; its roots are few, and in a light soil it

has a bad tendency to send its underground shoots a long way off, and thus take from the vigour of the Rose which is budded upon it; but with the seedling Brier this is to a great extent obviated. A careful excision of the eyes before planting will prevent them throwing up suckers, and I have in my own Rosery plants on the seedling Brier which have been there three or four years, and I have never seen a sucker on them. They root most profusely, and, consequently, give vigour to the Rose without overpowering it. It is also later, so that where there are both Manetti and seedling Briers grown, the Rose season is prolonged. It must be borne in mind, too, that there are some Roses which do but indifferently on the Manetti which flourish on the seedling Brier. Roses such as Henri Ledechaux, Capitaine Christy, and others of the Victor Verdier type, beautiful in appearance, but generally scentless, succeed well on it, while for Tea Roses its importance cannot be over estimated. Many of these the Manetti by its great vigour absolutely kills, but they flourish to perfection on the seedling Brier. Other stocks, it may be mentioned, have been used, such as Celice, Napoleon, De la Griffierie, and Garland, but they are practically nowhere in the estimation of the Rose grower; the three named, the wild Brier for standards, and the Manetti and seedling Brier for dwarfs, being those which are most generally used. The experience of the past year has also somewhat tarnished the reputation of the Manetti in another way. Complaints have been made, and not without reason, that excessive wet causes its roots to rot. In my own light soil even I have found this to be the case, while from growers in all parts of the country one has heard the complaint that their Roses have died. In some instances hundreds of Roses have been dug up and consigned to the back settlements of the garden or to the rubbish-heap, for, as a well-known Rosarian wrote to me, Roses are so cheap now that it is of no use trying to recover wounded ones; better get in fresh, healthy plants to supply their places.

I think that it may be taken for granted that in getting in plants it is well to consider the soil and climate both of the place where the Roses are to be grown and also from whence they are brought. To transfer Roses from the mild climate and loamy soil of a southern county to the bleak climate and hungry soil of a northern county cannot but be fraught with disaster; and, therefore, it is far better, if it be possible, to get Roses from some one near at hand, where the climatic conditions are the same, and those of the soil nearly so.

I have thought it well to write at some length on the subject of stocks because I am sure that much of the disappointment experienced by the owners of small gardens arises from the fact that they do not consider these matters; they order at haphazard from a nurseryman, and are contented to receive good-looking plants without at all considering whether they are likely to thrive with them, what their soil is, or what the stocks on which they are growing. If, as in other matters, they were to take into consideration their own position and then try and get their Roses to suit that position, they would not so constantly mourn over the fact that they cannot get their Roses to succeed.

DELTA.

WHITE ROSES.

THE most beautiful and recherché of all white Roses is Niphetos. This is one of the oldest of the Tea-scented Roses now in cultivation, for we find it described in the first edition of Paul's "Rose Garden," published in 1848. In the period of time from that date until the present moment, which has witnessed the disappearance of so many hundred kinds of Roses, after trials of long or short duration, Niphetos has more than held its own, and is daily increasing in popularity. To the exhibitor it is a tried and trusty friend, for where is the stand of flowers that would not be enriched and ennobled by the presence of one of its grandly-shaped, snowy, wax-like blooms? It is the admired and sought-after of all amateurs, whilst with the florists, who grow Roses for the sake of selling the flowers in the market, it is the backbone of their culture. Naturally a moderate-growing Rose, Niphetos may, with plenty of heat, be made to produce shoots of a stoutness and length that will bear comparison with the growth of any of the non-climbing varieties of the Tea Rose. Where large quantities of bloom

are required this seems to be the secret of success in growing it, and it is under a system of cultivation, carried on by means of a large degree of heat and moisture, that the thousands of flowers of this variety are produced which certain firms are continually pouring into the markets of London and other large towns. We would, therefore, recommend amateurs to bear this in mind, and if they have a warm corner in their Rose house let them reserve it for a plant of *Niphetos*, which will well repay them for their consideration. Other valuable white, or nearly white Roses, in the Tea-scented section, are *Alba Rosa*, *Julie Mansais*, *Madame Hippolyte Jamin*, *Madame Villermoz*, *Marie Guillot*, *Rubens*, and *Sombreuil*, all first class, but possessing withal the characteristic tenderness of their race, which renders the cultivation of all Tea Roses not devoid of risk, except under favourable circumstances, such as on a wall facing south, or on a well-sheltered border with the same aspect. Nearly allied to the Tea Roses are the Chinese or Bengal, and of these *Ducher* and *Mrs. Bosanquet* are the best whites. Amongst the *Noisette*, or autumn-blooming cluster Roses, *Aimée Vibert* and *Madame Massot* are pretty white Roses, especially valuable for climbing. The white Hybrid Perpetual Roses may be roughly divided into two sections, the one with a preponderance of *Noisette* blood, and the other comprising varieties of various parentage, and whose origin is not so clearly recognisable. The former, which may be termed *Noisette Perpetuals*, are chiefly characterised by a dark, shining foliage, the disposition of the flowers to come in clusters, and the tendency of the blooms to be more or less tinged with pink at the edges. The best of this section is undoubtedly *Boule de Neige*, and closely following it are *Louise Darzens*, *Baronne de Maynard*, *Coquette des Blanches*, *Madame Alfred de Rougemont*, and *Madame Noman*. *Coquette des Alpes* occasionally produces splendid flowers, but cannot be relied upon. Newer kinds of this class are *Perle des Blanches*, *Perfection des Blanches*, *Olga Marix*, *Mlle. Annie Marie Cote*, and *Madame François Pittet*. The other section of Hybrid Perpetuals includes the well-known *Madame Lacharme*, a splendid Rose in hot, dry summers, and the nearest approach we have to a white *Jules Margottin*; *Mlle. Bonnaire*, *Impératrice Eugénie*, *Elise Boëlle*, and *Mrs. Bellenden Ker*, the last a beautiful white Rose, the best of the *Bonnaire* family, but one which seems to have been overlooked by the majority of cultivators. These four Roses do well on the Brier, but poorly on the *Manetti* stock; their flowers are, however, of incomparable beauty. *Queen Victoria*, too, is a fine old white Rose, easy to grow; *Marquise de Mortemarte* is good as a pot Rose, but out-of-doors hard to manage, being very delicate; *Mabel Morrison*, if, as described, a white *Baroness Rothschild*, must surely be an acquisition. Amongst the Bourbon Roses and their hybrids, *Comtesse de Barbantanne* is grand in autumn, and so are the trio, *Acadie*, *Queen*, and *Souvenir de la Malmaison*, although none of them are pure white. Autumn is their flowering season, and from August onwards until the advent of frosty weather they will furnish a constant supply of beautiful blooms. We must admit, however, that it is amongst the summer-flowering kinds that the most gorgeous and effective of all white Roses are to be found, and unexcelled in this respect are the Hybrid *Noisette Madame Plantier*, and the *Damask Madame Hardy*. These two Roses will form huge bushes as dwarfs, and immense heads if grown as standards, in a manner that none of the autumnal Roses can approach, and during their season of flowering they present a dense and unbroken mass of white of dazzling purity and brightness. *Miss Ingram*, as a summer-flowering Rose, is good in some seasons. The best white Moss Roses are *Comtesse de Murinais*, *Reine Blanche*, and *White Bath*; these flower in summer only. Perpetual White Moss produces beautifully-mossed flowers in autumn as well as summer. The *White Provence*, or *Unique*, is a pretty summer flower, as is also the *Alba*, *Madame Legras*. As climbing or running Roses, the *Ayrshire* and *Evergreen* families furnish us with some good kinds, such as *Bennett's Seedling*, *Dundee Rambler*, and *Queen of the Belgians*; *Donna Maria Rampante* and *Félicite Perpetué*; whilst the white *Banksian* may be got to climb, and produce in profusion its fragrant blossoms on a south wall, as the foot of which may be trained the *Macartneys Marie Leonida* and *Alba simplex*.

The Nurseries, Waltham Cross.

ARTHUR W. PAUL.

PLANT CULTURE IN MARKET GARDENS.

SHOW PELARGONIUMS.—Both show and zonal Pelargoniums are grown, perhaps, in larger quantities than any other market plants; the uses to which they may be applied are so numerous that there is always a demand for them. Early in the year, their blooms are valuable, and later on the plants are required for window-boxes, flower gardens, and small greenhouses. One of the largest growers of show and fancy varieties is Mr. Beckwith, of Tottenham, who sends to market yearly from 80,000 to 90,000 plants of both kinds. Cuttings of these are struck as early in spring as they can be obtained and potted on until they occupy 5-in. and 6-in. pots. They are given a little heat and abundance of air night and day when the weather will permit, and are copiously watered whenever they require it. The only kind of stimulant used in this great plant factory—for such it may be called—is soot water, which is applied at different degrees of strength, according to the stage of growth in which the plants may be. This has the effect of expelling worms from the soil, and imparting to the foliage a green, healthy appearance. The first batch of plants, which consists of early-flowering varieties, comes into bloom in February and March, and others are brought on in succession, the last being usually disposed of by the end of June. Few of the plants exceed 12 in. in height; they are, however, remarkably bushy, and furnished with large, healthy leaves down to the pot, and every shoot bears noble trusses of finely-developed blossoms. One of the principal kinds used for early-blooming is *Red Gauntlet*, a kind which I once saw covering a back wall of a lean-to house, from 10 ft. to 12 ft. high, and 120 ft. in length. The pots in which the plants were growing were plunged in the border, and the roots had long ago passed through the bottoms of the pots into the soil below them. The shoots were tied to the wall, and at nearly every season of the year abundance of bright-coloured blossoms could be gathered. During March and April the amount of bloom was simply wonderful. Little attention was paid to the plants beyond clearing off decayed leaves and tying in the shoots occasionally. A dark variety named *Bonnie Charlie* is also used for forcing. Its habit of growth is not particularly good, but its flowers are of a rich dark, velvety crimson, and old plants of it, when kept liberally supplied with water, grow and flower all the year round. *Beauty of Edmonton* is also an excellent kind, the flowers having a fringed edge similar to those of the well-known *Dr. Andry*. In colour they are brilliant crimson, and are more conspicuous than those of any other variety. Mr. Hayes, another great grower, at Edmonton, never subjects his Pelargoniums to any fire-heat whatever after the plants are rooted, except during very severe weather. Abundance of light, air, and water is given them, but they receive little in the way of stimulating manures of any kind. Nevertheless, the foliage is very large and beautifully green, and almost conceals the pots. The flowers, too, being produced without forcing, last for a much longer time than those on plants that have been subjected to strong fire-heat and stimulating manures. Some growers of Pelargoniums place good, bushy plants of early-flowering kinds into large pots during summer and keep their blooms regularly picked off, by which means the plants yield a good supply in autumn and spring, when flowers are greatly wanted. Others cut back their plants after they have done flowering in August, and, as soon as they break afresh, pot them and place them in a gentle heat, keeping them well supplied with manure water, and, thus treated, they continue to bloom all through the winter and

spring. A fine double-flowered show *Pelargonium*, named Dr. Masters, which originated with Mr. Reeves, of Acton, from a sport from the old Fire King, is one now much prized for its faultless habit of growth, its wealth of deep green foliage, and its abundance of maroon-crimson flowers, which last for a much longer time in a cut state than those of any other market kind. Among other good varieties may be named Digby Grand (of the Dr. Andry type), Triomphe de St. Mandé (crimson), Duchess of Bedford, and Empress of India.

ZONAL PELARGONIUMS.—These are largely grown by nearly all market gardeners who have Vineries or other fruit houses; they profitably occupy such houses whilst the fruit trees are at rest, and they are cleared out before the shade of the trees interferes with them. In many places, also, houses are wholly devoted to zonal *Pelargoniums*, and, in that case, they are often made to serve two purposes; they furnish an enormous amount of cut blooms during winter, and make neat, compact, and well-flowered plants with which to decorate the balconies and window-sills of London houses during summer. *Vesuvius* and *Master Christine* are the kinds grown in the greatest quantity; a few white-flowered kinds are also grown, but on these very little value is set. Pink bloom is less sought after in the market than scarlet, and there is also less demand for the plants in summer. Cuttings of *Pelargoniums* for winter blooming are struck in June, potted into 5-in. pots when well-rooted, and freely exposed to the sun and air by being placed in an open spot out-of-doors. Towards the end of September, when the weather begins to be showery and cold, the plants are removed to the houses in which they are to flower, each one being placed on an inverted flower-pot close to the glass, and sufficiently distant to allow of a free circulation of air amongst them. This prevents the leaves and blooms from damping off during wet and sunless weather. The plants are potted in good sandy loam, all kinds of manure or leaf-mould being avoided, as these only promote rank and vigorous growth at the expense of bloom. The great point aimed at is to get the wood hard, short-jointed, and well-ripened as early in the autumn as possible, and, in order to accomplish this and keep the plants dwarf and compact, no more water is given them at any stage of their growth than is absolutely necessary to keep them in a healthy condition. When placed in the houses, a dry atmosphere is maintained by means of hot-water pipes and free ventilation. Should any of the plants show a want of vigour, they receive a little guano water, which soon improves their condition. The flowers are gathered regularly every evening, and by the same person, who takes great care never to cut a bloom one day that would be improved in condition by being left until the next. As they are gathered, they are placed in shallow trays, carried by boys on their heads, and are at once conveyed to the packing shed to be gummed. This process is likewise performed by boys, who, with a finely-pointed stick, deftly drop the smallest possible quantity of prepared gum into the eye of each blossom; this keeps the petals stiff, and prevents the flowers from falling to pieces. When gummed, they are packed in boxes ready for market, where they fetch from 9d. to 1s. per dozen trusses, according to size and quality. Notwithstanding that hundreds of dozens of trusses are gathered weekly, *Pelargonium* houses in January present a display of bloom little inferior to that in the flower-beds in the metropolitan parks in the middle of summer. As soon as *Pelargonium* blooms become plentiful, market prices for them fall considerably; the plants are then cut

back and prepared for their summer duties. The cuttings taken off are struck in boxes, and sold, as in the case of *Calceolarias*, &c., to the trade for bedding purposes. The cut-down plants, when again established and full of bloom, are taken to market, where they fetch from 6s. to 9s. per dozen. Some growers have rather a different practice. They strike their cuttings in autumn, grow them on in good sandy soil, keep them in houses, and then pot them in 6-in. pots; the bloom which they produce during winter is, as in the case just stated, cut for market, and in April and May, when the plants are in full flower, they find a ready sale for furnishing large vases and for planting out in beds in which immediate effect is desired. The shoots are stopped during the growing season in order to make the plants bushy, and, when coming into bloom, liberal supplies of manure water are given them. Larger specimens are obtained from cuttings inserted in spring; the shoots of these are regularly pinched in, and in the following spring large, bushy plants furnished with fine spikes of bloom is the result.

COLOURED-LEAVED PELARGONIUMS.—These have hitherto been but little grown for market; lately, however, a few growers have taken them in hand, and find no difficulty in disposing of well-coloured plants at remunerative prices. The principal part of the propagating is done from January to March; but it may be said to be always going on. The cuttings consist of points of the shoots taken off when the wood is ripe, firm, and just starting into growth; if they have four leaf-joints, that is sufficient. These are put into 2½-in. pots, and afterwards shifted into 3-in. pots, in which many of them are marketed. Many of the commoner varieties are planted out in nursery beds during the summer to provide more cuttings; these hard cuttings grow into rooted plants quickly. The soil used for the gold and silver Tricolors consists of about two parts light loam, one part leaf-mould, with silver sand added; the gold and bronze kinds are grown in a stronger loam with a little well-decayed manure. These plants are grown in ordinary plant houses, light and airy, and, therefore, well adapted for the purpose; but the plants are not kept so near the glass as one might suppose. During winter, a temperature of 50° is maintained, rising to 60° in the sun-heat. Plenty of air is given on all favourable occasions, but during dull weather water is applied but sparingly. Some growers send to market yearly as many as 20,000 plants in 4-in. or 5-in. pots, bushy, and well supplied with ample, richly-coloured foliage. The plants are usually sent to market packed closely together in shallow boxes, each of which holds a dozen or more pots. Both for window ornamentation and for planting in small gardens, these coloured-leaved *Pelargoniums* are eagerly sought after. A few of the best kinds of golden Tricolors grown for market are Peter Grieve, Macbeth, Lady Cullum, Golden Queen, and Florence. These are mostly good growers, and have bold, richly-coloured leaves with good dark zones. Among silver tricolors may be mentioned Lass o' Gowrie (a capital sort, free, as regards growth, and very showy), Empress of India, and Dolly Varden. The best bronze or tricolors are Mrs. Harrison Weir, W. E. Gumbleton, and Marshal MacMahon.

IVY-LEAVED PELARGONIUMS are also grown in large quantities for draping the edges of window-boxes, and there has lately been raised some beautiful double-flowered kinds belonging to this class which will, when known, no doubt, be largely grown for such purposes, and their flowers are useful for cutting.

C. W. S.

THE FRUIT GARDEN.

PINE HOUSES.

"A GARDENER" (p. 48) may grow Pine-apples successfully in two kinds of structures, one a lean-to, the other span-roofed. We grow them in both, and like the one about as well as the other. Lean-to houses may be of any width and height, but we prefer them from 16 ft. to 18 ft. wide, and about 12 ft. high at the back; a high roof with the plants far from it is undesirable. Such a house as this may have the interior arranged in two ways, either with a bed about 10 ft. wide and a pathway all round, or a pathway along the centre, and a bed at back and front. In this case, the wall of the back bed should be raised 2 ft. above that of the front, so as to keep the plants up near the glass. With this arrangement there should be two rows of 4-in. pipes laid along the bottom of the pathway, with grating above on which to walk; two rows along the front, and two rows along each bed to afford bottom-heat. With the bed in the centre, at least, a double row of 4-in. piping should go all round the house, and three or four rows should be placed in the bottom of the bed. Perforated gratings answer best for cornering over these bottom-heat pipes, but they may be covered with stones or rough rubble, so that the heat may get freely up into the fermenting material. The beds should not be less than 2 ft. in depth, and the flow of water in the pipes should be regulated by means of good valves. In many houses much heat is wasted by not attending to this. I may add that a lean-to house should be placed with its face due south, and a span-roofed one with its ends north and south. A span-roofed house, about 12 ft. high and the same in width, with a 4 ft. bed on each side of the pathway, is a favourite house of mine for Pine culture, but we have grown good fruit in all kinds of houses, the chief requirement being plenty of heat during certain stages of growth. I have entertained an opinion for a long time that Pines in general do not get sufficient water at the root. I would strongly recommend all concerned in their culture who can procure Oak and Beech leaves to store a large quantity of them for plunging and other purposes, such as hotbed making. We collected some hundreds of cartloads of them this winter for such purposes, and when useless for all else they make valuable leaf mould and manure for root crops, &c. At one time we used tan in which to plunge our Pines, but it did no better than leaves, if so well, and as a manure afterwards it is quite useless.

CAMBRIAN.

It will be found, I think, that a hip-roofed house facing due south will answer better for Pines than one of any other form. Such a house will admit back light from the ridge, which should be about 4 ft. in depth. It should have a path beneath occupying the full space, [and a narrow path on the front. The bed devoted to the plants, should be raised sufficiently high to keep them well up to the glass. For plunging some prefer Oak leaves, where these are to be had in quantity, but nothing equals fresh tan, when not ground too fine. Fresh loam is the only soil suitable for Pines, and the better it is in quality the better the results may be expected to be, other cultural details being rightly carried out. I have, however, often seen good useful Pines grown in loam that was far from being such as one would select if better was obtainable.—T. BAINES.

The most suitable structure for Pines is a span-roofed pit, with sufficient piping to keep up the heat to 70° in severe weather, with ample ventilation at top and each side. It should have a bed in the centre, or a walk in the centre and a bed on each side, according to circumstances, with a couple of pipes underneath the bed, which should be regulated by means of a valve. The side ventilators should be opposite the hot-water pipes so as to warm the air as it enters; they should be open a little all the year round on the side opposite the wind, it keeps the atmosphere in motion without allowing the heat and moisture to escape, and the result is sturdy growth and good flavoured fruit. The best plunging material is tan, which should be fresh, but if very wet it should be turned over a few times before plunging the plants in it, as the heat is then steadier and more durable. The bottom heat should never exceed 80° or 85° at most, otherwise the foliage will be long and narrow instead of short and broad, the forerunner of good fruit. A suitable soil is the surface of an old pasture with plenty of fibre in it cut about 2 in. thick, and if in good condition it may be chopped, or, better still, pulled in pieces fresh and green, and it should be mixed with a good sprinkling of rough sand or soft burnt brick broken small. Where top sods are not procurable Pines will succeed almost in any mixture of soil provided it is open and sweet and pressed solid in potting, which leaves less room for water to stand in the pots. Never mix any manure with the compost, but give weak liquid manure regularly, as it has always a tendency to sour the soil and stop the progress of the roots.

J. SMITH.

Waterdale.

LADY BEATRICE LAMBTON PINE-APPLE.

THIS is one of the noblest and handsomest varieties of the king of fruits which has yet been obtained. It is one of about thirty seedlings raised some years since from the Montserrat, at Lambton Castle, by Mr. Stevens, who was then gardener there; and it has since been proved to be both distinct and desirable by Mr. Hunter. Other distinct varieties of considerable promise, have, we believe, been observed amongst the seedlings, as well as some few which are remarkable as curiosities. We learn from Mr. Hunter that Lady Beatrice Lambton is somewhat taller than the Smooth-leaved Cayenne, and more erect in its habit of growth. The leaves are dark green and prickly at the edge, the spines being strong and widely set, about four to the inch. The flowers are purple. The fruit is very large, pyramidal, from fourteen to fifteen pips in depth, and averaging about 10 lb. in weight (it has been grown to 11 lb. 7 oz.), the individual pips being broad, measuring 1 in. across, plump when properly swelled, of a deep orange colour in the prominent parts, yellow in the furrows, the scales or bracts subtending each pip being of a bright coppery-red. It will thus be seen that it is really both a noble and a handsome fruit. The quality also is of a high order of merit. As regards its flesh and flavour, the former, in the examples we have examined, was of a pale semi-transparent yellow, with soft yellow fibres towards the inner axis or centre, and exceedingly tender and melting towards the circumference. The flavour was rich and excellent, with very abundant refreshing juice. Mr. Hunter informs us that in the case of a fruit of 10 lb. weight, cut at Christmas, 1873, and used for dessert, he poured from the dish when it was brought from table three-fourths of a tumblerful of the syrupy juice, and our experience quite accords with this statement. This very abundant juice is, in truth, one of its characteristic features, and one which points to its great value as a summer fruit. When ripened in spring, it is found to be quite equal to the Cayenne and Charlotte Rothschild; indeed, Mr. W. Thomson, of Clovenfords, states that having often tasted it both in summer and winter, he is of opinion that while it far exceeds in size the Enville, which it resembles in shape, it equals the Queen and Smooth Cayenne in flavour, and in this respect far excels them in winter. Mr. D. Thompson speaks approvingly of its very free fruiting habit, and also bears testimony to its beauty and good qualities, it being, he remarks, "the most handsome Pine in cultivation," and in the winter season "remarkably juicy, and much better flavoured than Smooth Cayenne or Charlotte Rothschild." The fruit grows close down in the heart of the plant, quite the opposite of its parent, which throws its fruit out of the foliage. Various causes, which it is not necessary here to discuss, have conspired to prevent this fine new Pine from being put into commerce at an earlier period, one of which, we learn, is its shyness in producing suckers. Its merit has, from the first, been fully appreciated at Lambton. A sufficient stock has now been obtained to permit of its being offered to the public; and for this purpose it has passed into the hands of Messrs. Ireland & Thompson, of the Cragleith Nurseries, Edinburgh, by whom it is being distributed.—"Florist."

Protecting Fruit Trees.—All small fruit bushes should now be protected from birds. The best material I find for this purpose is white cotton, known as crochot cotton; it does not break during strong wind as finer material does. It should not be placed in straight lines; on the contrary, the more angles the better, as it is then more difficult for the birds to get between the threads. Until I adopted this plan we never could get a crop of fruit, but since we have done so we have never failed. The trees, moreover, are spoiled by disbudbing, and have to be cut back. For protecting wall trees I use fishing nets and hexagon nets, hanging them from 16 in. moveable coping boards, and supporting them on small poles placed in a slanting direction from the wall. By this means we get good crops of fruit. Last year I tried a new material made of cotton netting, and I find it very useful, not only for protecting trees in bloom, but also for preserving ripe Strawberries from birds, and other ripe fruits from wasps, bees, flies, &c. During the severe frost, too, which we have had I have used it to great advantage in the fruit room.—W. D. Maidstone.

King of the Pippins Apple.—The quality of any variety of Apple is, no doubt, considerably influenced by soil and climate, but this sort, as "Cambrian" says, is generally a free bearer; still in no part of the kingdom that I have either grown or tasted it could it be classed amongst the best kinds for flavour. Cox's Orange Pippin is little inferior to it as a free bearer, and very much better in flavour, and there are a good many others I could name alike superior to it in the last named property. King of the Pippins with me always has been very indifferent, cooked. "Cambrian" possibly may not have the true kind.—T. BAINES.

NEW OR RARE PLANTS.

BROUSSONETIA PAPYRIFERA VAR. BILLIARDI.

THE Paper Mulberry (*Broussonetia papyrifera*), which, by-the-by, should be more generally planted in the south and west,

Broussonetia papyrifera var. *Billiardi*.

presents a number of curious varieties of foliage, even in a wild state, and some of them have been in cultivation; others have originated in gardens from seed. The accompanying

A Leaf of *Broussonetia papyrifera* var. *Billiardi*; half natural size.

illustrations represent a curious cut-leaved variety, raised from seed by the late Mr. Billiard, of Fontenay-aux-Roses. It is very near the old, though rare variety *dissecta*, but differs in its more slender branches and less compact habit.

W. B. HEMSLEY.

Paraffin as an Insecticide.—As yet I have had no occasion to use this oil for killing insects, but if it be half as good as it is said to be it would be difficult to overrate its value. If it kills insects so readily it will also, I should say, prevent them from appearing, and, acting on this principal, we are this winter putting a little paraffin in all the water with which we wash Vine rods and Peach trees, also in the water with which the houses are cleansed, and in the mixture with which any of them are painted. I do not think any one who wishes to guard against insects during the coming season could do better than adopt this plan.—CAMERIAN.

THE INDOOR GARDEN.

WINTER GARDENS.

Nothing is more pleasing in the whole range of gardening, than the effects which may be produced in a tastefully arranged and well-kept winter garden. We are therein enabled to give some slight idea of the general aspect of tropical and other vegetation. The preconceived and popular notion of a winter garden is a roomy, lofty structure, wherein Palms, &c., grow to tree size. This is so far correct; such a structure represents a perfect winter garden; but it is equally certain that the same principals which serve to guide us in the arrangement of large houses are applicable to smaller structures, the furnishing and keeping of which will entail but a moderate outlay. It is scarcely necessary to dwell upon the uses and advantages of a winter garden; its name sufficiently indicates the end and aim of its existence, a place of resort when inclination, health, or weather forbids wandering far from home. One of the prettiest winter gardens I ever saw was very small; it had been built for a lady in infirm health, and was attached to the house. In it was nothing rare or tender, but the subjects were suitable, tastefully arranged, and the hands of the owner herself kept them healthy and clean by means of frequent washings and spongings. Many an hour was thus pleasantly spent in the exercise of a loving care, which had its reward in the bright appearance of the plants. Winter gardens may be placed in two categories, viz., those in which heat is only applied to exclude frost, and those wherein a regular temperature is maintained. It will naturally be seen that the plants used for the two places must be somewhat different in character. In the former we must rely upon the inhabitants of temperate climes, but which we cannot well grow the year through in the open air in this country, such are some of the *Araucarias*, some Palms, also, Ferns, *Camellias*, *Azaleas*, *Acacias*, &c.; in the latter we get a great variety of subjects, and are enabled to impart a strong tinge of tropical verdure to the arrangements by employing Palms, *Pandanads*, *Streitzias*, *Brownias*, &c. The great mistake made in winter gardens is overcrowding; it is just the same here as in outdoor planting, thinning is not done in time, and the whole degenerates into a weary tangle; ultimately something must be taken away, with the result of more fully exposing the debilitated specimens.

Now, let us suppose that we have a house to arrange—anything between 12 ft. and 20 ft. in height, and some 20 ft. wide by 40 ft. long. This, it will be seen, is not a large house, but it is spacious enough to allow of the specimens acquiring handsome proportions. Starting from the entrance—or, if the interior be commanded by any of the apartments of the dwelling, we must commence there—we should in the first place have before us an open breadth of green turf (*Selaginella*), which is truly beautiful when well kept. Towards the far end I would arrange the water, if such is to be introduced; and I would always have the limpid element therein if possible. But here a word of caution: unless a constant supply of bright fresh sparkling water, such as a fish might thrive in, can be assured, do not attempt it, as nothing is more repulsive and dismal than dirty stagnant water. Hardly second in importance is the shape and arrangement of the water basin: anything formal—having the appearance of a large cup sunk in the ground—must be avoided. The rockwork should be so arranged as to occupy about one-half of the water margin, and must be planted here and there with trailing and drooping plants, Ferns, &c. The edge of the water basin should also be studded with plants that will serve to break its monotony—*Maidenhair*, *Hare's-foot*, and other dwarf-growing Ferns; *Ficus repens*, *Tradescantia*, &c., will serve admirably to drape the lower portion; whilst the upper part may be studded with hardy *Cacti*, *Cobweb Houseleek*, and some kinds of plants which do not need constant moisture at the roots. Do not run into the too common error of building a rockwork without making ample provision for the growth of plants thereon. Shallow pockets, containing some 3 in. or 4 in. of soil, are of no use whatever. Anything planted therein to remain permanently will, as soon as the soil is exhausted, exhibit a meagre and unsatisfactory appearance. The roots should be

able to work their way freely downwards, so that they may be continually finding fresh nutriment. In adjusting the various portions of the rockwork, fissures should be therefore left so that there is no hindrance to the attainment of these conditions. This care is all the more necessary where air is freely admitted into the house, as there is then great difficulty in supplying sufficient moisture when all the roots are near the surface. At the back of the rockwork, and so placed that it spreads and overhangs the same, some such graceful-habited plant as an *Araucaria excelsa* or a Palm should be planted. Spreading away from each side, Tree Ferns, *Dracenas*, Bamboos, and such free-growing ferns as *Pteris arguta* and *Nephrodium molle*, should be so arranged that they have space enough in which to develop. The walk will naturally run round the building, and should be made to wind in such a manner that the borders and corners are of unequal dimensions. This will allow of the arrangement of sundry little groups, each one having a character of its own, and will at the same time afford ample opportunity for the placing of single specimens. Should there be a dead wall, which, if the house be connected with the dwelling, will probably be the case, it should have affixed to it some neat trellis-work, and for covering the same I do not know of any thing better than Camellias. They lend themselves well to this kind of work, and the green is so lustrous and deep that, if they did not possess the additional merit of furnishing exquisitely beautiful flowers, they would on that account alone be invaluable for our present purpose.

A few climbing plants are desirable in a winter garden; it is here, indeed, that they appear to most advantage, and are better enabled to develop their true character than in more confined quarters. There is a good variety of climbers suitable for a cool house: *Begonia jasminoides*, *Lapagerias*, *Cobea scandens variegata*, *Mandevilla suaveolens*, and *Rose Maréchal Niel*, are some of the best; whilst for pillars *Abutilons*, *Rhynchospermum jasminoides*, *Plumbago capensis*, and *Habrothamnus* are all suitable. Flowering plants of all kinds may of course be introduced the whole year through with good effect. If *Fuchsias* are left in the turf, the pots may be sunk; and *Hycinths*, *Tulips*, *Violas*, and *Primulas*, &c., will have a very pretty effect thus treated.

The plants above enumerated are all suitable for a structure which is only heated to exclude frost. If a continual warmth is to be maintained, then for the *Camellias*, *Acacias*, *Araucarias*, &c., we must substitute denizens of warmer regions. The arrangements may, however, be conducted in much the same manner as already recommended, only that it should be borne in mind that the more heat the more rapid will be the development of all plants subjected to it. A Palm in a warm house will grow much faster than when kept quite cool, and the growth of tropical plants in general is much more luxuriant than those which come from temperate climes. I have preferred to treat in a more special manner of the cool house, inasmuch as it is better adapted to general requirements than when heat is constantly applied. The latter form of winter gardens demands a much greater amount of attention, and entails more expenditure, than if those plants only are employed which require merely the exclusion of frost. The arrangements detailed herein are not to be considered arbitrary; individual tastes and fancies should be allowed free scope in the way of disposing the plants; but the future career of the specimens must not be sacrificed in order to gain an immediate effect. I have endeavoured to show that the creation and maintenance of a winter garden is not a work involving a vast amount of labour and expense. I have often had an opportunity of witnessing the enjoyment derived from such a structure. In conclusion I may observe that, whatever may be the class of plants grown, there should be no attempt made to force growth, as such treatment will inevitably have the effect of distorting and destroying the symmetry of the subjects so treated. It is better to let Nature develop herself in her own way and take her own time thereto, as, with constant supervision and attention to her wants, she will not fail in the end to reward us for our labour.

J. CORNHILL.

Byfleet.

Begonia hydrocotylifolia manicata.—This is a hybrid between the two species whose name it bears. It has a vigorous,

sturdy habit, flowers freely in winter, and when not in flower the whole plant has a strikingly handsome appearance. Cuttings of it taken off at midsummer, inserted singly in small pots filled with sandy soil, will make pretty little flowering plants by Christmas. A little extra warmth such as that furnished by a Cucumber frame will be useful for striking the cuttings and giving the young plants a start, but afterwards they will succeed in a warm greenhouse or intermediate house.—E. HOBDAY.

TRITONIA AUREA IN POTS AND PLANTED OUT.

If we take the year through till *Chrysanthemums* make their appearance in autumn, there is generally a dearth of orange or yellow flowers wherewith to embellish greenhouses or conservatories, and these are colours that are, perhaps, more telling than any others, especially when associated with scarlet *Pelargoniums*, or the bright blue *Browallia elata*. The latter should be largely grown in every garden, as it is one of the best plants possible for furnishing cut flowers for bouquets or vases, and, by sowing at intervals, it may be had in good condition the whole year round. *Tritonia aurea*, as I have said, associates well with this, and is not half so well known as it deserves to be, for, besides being exceedingly effective, it is a plant that is very easily cultivated, all the shelter or protection which it requires when grown in pots being that of an ordinary cold pit or frame, in which it thrives better than in any other situation. If kept in any place where the air gets dry, red spider is sure to attack its flag-like leaves, and, once this pest effects a footing, the health of the plant soon fails. Probably its liability to be attacked by red spider is one of the reasons why it is so seldom seen in gardens, but if those who have hitherto failed with it will only keep it entirely out of dry houses until it comes into bloom, they will not have the least difficulty with it, for it is of such a hardy nature that it will live and thrive well planted in any sheltered border where the soil is moderately light and well drained. For purposes of cutting, this is by far the best way of growing it, as then it entails no labour in watering, and is much more floriferous than when restricted to the limited area of a pot. A row we have of it, planted close to the foot of a low south-west wall, affords great quantities of bloom, and saves running to the greenhouse, and all the preparation which we made for it was digging in a quantity of sand and leaf-mould, so as to lighten the soil, and keep it in a loose, open state. In this the plants spread and travel underground, somewhat resembling in this respect the Couch Grass. The mistake which many make in growing *Tritonia aurea* is drying it off; this its pseudo-bulbs will not bear, as they are not sufficiently large or fleshy in themselves to keep alive, unless the soil be moist.

The bulbs being at present comparatively dormant, now is the best time to get them, or to set about dividing and planting or potting them. If grown in the latter way, 8-in. pots are the handiest and most suitable; they should be drained with a few crocks, and over these some of the roughest portions of the soil should be placed. A mixture of peat and loam in about equal proportions suits them best, but either will do alone, the latter especially, if it be fresh and fibry. As they look best in a mass, from twelve to eighteen bulbs will be required for pots of the above-named dimensions, and these should be of the largest that can be picked out, and be regularly distributed and covered to the depth of about 2 in. This done, the next thing is to give them a soaking of water to settle the soil, when they will at once set to work in forming fresh roots, and till they have made plenty of these and some top growth the soaking in question will afford sufficient moisture to carry them on, as, till they get well into leaf, they absorb but little, and are injured if kept in too wet a condition. As before observed, a cold frame during their earlier stages of growth is the best place for them, and, if plunged in ashes so as to prevent frost reaching their roots, little, if any, covering beyond the glass will be needed, unless severe weather sets in. After the middle of May or so it is a good plan to plunge them outdoors, as then the genial rains and refreshing night dews help much in keeping the foliage clean and free from red spider. An occasional syringing and abundant supplies of water as growth progresses and summer advances will be

found to suit them perfectly. As soon as they begin to show bloom they may be taken to the greenhouse or conservatory and arranged so as to produce the best effect. As the flowers fade the right course is to lessen the water supply, but not to that degree as to bring about actual dryness, the only object being to ripen and rest the plants previous to potting, an operation that should be performed as soon as the foliage shows signs of decay. Any spare or weak bulbs or suckers that may be showing themselves will then come in for planting in any position similar to that previously alluded to; in doing so they should be put in at a depth of about 5 in. or 6 in., and the surface of the soil should be coated over with Cocoa-nut fibre or decomposed leaves, both of which are capital non-conductors, and keep out frost better than anything else.

S. D.

HEATING AND VENTILATING IN COLD WEATHER.

I was pleased to see (p. 30) Mr. Fish's remarks upon this subject, for it is a most important one. Much loss of fuel is annually sustained from over anxiety to keep fires going briskly in frosty weather. There are two sources of heat for warming glass houses, viz., the sun and the fire, and these should aid, not run counter to each other. The sun, of course, we cannot influence, but on a bright frosty morning we can anticipate his rising, by an hour or two, and discount, so to speak, his warmth, by checking the fire betimes leaving the sun his proper share of work to do. To keep fires burning briskly when the sun is shining brightly, no matter how sharp the morning may be, is not only a waste of fuel but in many cases may do positive harm. When the warmth from a bright sun meets the heat from a brisk fire under a glass roof, it is next to impossible to maintain a genial atmosphere in the house. In many cases all the fruit houses are crammed full of bedding plants in winter and spring, and they must be kept secure from frost; the least amount of fire-heat will effect this, and it should be turned off altogether the first thing in the morning. I am of opinion that in the ventilation of glass houses in winter and spring, some means should be specially employed to make the cool air from the outside, whenever it is necessary to admit it, pass over the heating apparatus, or, if this cannot be done, then cover the open spaces with canvas or something similar that will act as a respirator in breaking up and distributing the cold currents; air, when disseminated, causes little or no draught when entering a building, but I agree with Mr. Fish that if the fires be kept down, but little ventilation will be required, especially in large houses. Small houses heat more rapidly and require more attention, both in the management of the fire and also in ventilating. As regards cool houses, devoted at this season mainly to the sheltering of plants for open-air decoration in summer, if the houses be kept altogether closed, on bright days, even if very frosty, a vapour will be raised inside by the sun's warmth, and I think it always best to give enough ventilation to induce this to escape rather than allow it to become condensed and drop amongst the plants. The proper management of fires for horticultural purposes is an art that requires much painstaking thought. There are two main principles that must be insisted on; the first is thorough cleanliness about the boiler, and the second is the careful management of the draught of the fire, so as to insure just the right degree of combustion and no more. Wherever the smoke passes round the boiler, there soot will accumulate, and the waste matters of combustion are sometimes carried forward by the draught of the fire. There should therefore be periodical cleaning and scraping of all boiler flues, so that the heat of the fire may come into direct contact with the iron surface of the boiler. The furnace doors should fit properly, or the draught cannot be regulated, and unless this is carefully attended to, a good deal of the heat may escape up the chimney and be wasted. In heating horticultural buildings a liberal outlay for piping in proportion to the work to be done will be found true economy. Iron pipes, if not severely strained, wear out but slowly; but if the apparatus has to work at a high pressure, in order to maintain the requisite amount of temperature, there will come a time when something—either boiler or pipes—will give way, and the period of the greatest trial will be during severe frost, when a disorganised heating apparatus is always a source of danger and annoyance. Besides the greater danger of a mishap to an overworked apparatus, there is the unhealthy character of the scorching heat to contend with, and all who have had to work such apparatuses know that it is a great mistake, both from a cultural and economical point of view, to stint the amount of piping.

E. HOBDAY.

Hebeclinium ianthinum.—To the casual observer this plant has the appearance of an enlarged variety of *Ageratum*, and its

flowers do bear some resemblance to those of that family, both in structure and colour, but it has a shrubby habit, and flowers naturally in winter. As it is so easily cultivated, and supplies a colour that is always scarce, it ought to find a place in every collection. It is generally classed with stove plants, but it succeeds perfectly in an intermediate house. A little extra heat during the time of growth will be beneficial, but when in flower it may be moved to the conservatory, and, in a dry atmosphere, its large clusters of violet-coloured flowers last a long time in perfection. It will succeed in fibry loam and peat, with a sprinkling of sand, and it flowers best when not over potted. Cuttings made of its half-ripened wood strike freely in bottom-heat, and pretty little blooming plants, one year old, may be had in 5-in. pots, or, under good culture, large, handsome specimens may be produced in from two to three years.—E. HOBDAY

THE FLOWER GARDEN.

CARPETING BULB BEDS.

THE necessity for covering beds planted with Dutch or other bulbs, especially sorts which make scanty foliage, is so obvious that carpeting them with something green does not require recommendation. These bulbs are planted near the end of October or in November, and until their foliage begins to show itself aboveground early in spring the beds are simply a bare blank. To remedy this there are many dwarf plants which may be planted thickly between the lines of bulbs, or planted so as to cover the surface of the beds through which the bulbs may push their leaves and flower stems as they happen to come up. The best plan is to adopt a kind of double planting, first filling up the beds with bulbs as may be determined upon, say with Hyacinths or tall Tulips in the middle, banding them round with dwarfier Tulips, Crocuses, Anemones, or other bulbs. The place for the bulbs should be marked off in lines, either straight or curved, according to the shape of the beds, planting the bulbs with a dibble; after inserting the bulbs leave the holes open over them so that their exact positions may be seen; then proceed to plant the carpeting plants in single or double lines between the bulbs, according to the size of the plants used. The planting of these effectually fills up the holes made for the bulbs, and one dressing of the surface is sufficient for all. It is necessary to remark that in planting between or among rows of bulbs, varieties of plants must be used suitable to the size of the foliage and colour of the flowers of the bulbs, as, for instance, the plants which would suit among beds of Hyacinths or Pottebakker Tulips would not suit amongst Snowdrops or Scillas, and, again, attention must be paid to the colour of the flowers of the carpeting plants, inasmuch as both they and the bulbs will be in bloom at the same time. For instance, the effect of blue Hyacinths would be entirely spoiled by having a carpet of some purple-flowering plant beneath them. Fortunately for spring flower gardening there are no lack of dwarf plants with flowers of all shades of colour suitable for our purpose. Suppose the centre of a bed is filled with blue Hyacinths, the surface of the bed may be carpeted with *Gnaphalium lanatum* in a very ready way at the same time as the bulbs are planted by simply taking off cuttings of the *Gnaphalium* with four or more good leaves attached to them and dibbling them between the rows of the Hyacinths. It will be found that not a leaf will be lost, and the cuttings will soon be rooted plants covering the bed well before the Hyacinths are in bloom. Of course, in the absence of rooted plants, which are preferable, or in the absence of rooted and prepared plants of *Arabis alba*, cuttings of this showy spring plant may be inserted in the same way with the certainty that they will all be rooted by spring and will flower profusely. If the variegated variety of the *Arabis* be used so much the better; these same plants will also answer amongst red Hyacinths. Among red and white Hyacinths the dwarf, early-flowering *Viola Blue King ansers* well, as do also *Aubrietia purpurea*, *A. deltoidea*, and the variegated form of *A. purpurea*. These may be planted in much the same way as the *Arabis*, only in tufts instead of single cuttings; but good-rooted tufts properly prepared are the best. These plants may also be used for carpeting among the taller Tulips, such as the Pottebakkers, *Rex rubrorum*, *Canary Bird*, and others. *Aubrietia græca* is likewise specially suited among the tall white

and yellow Tulips as it is taller than the other Aubrietias. Another pretty plant for carpeting among white Hyacinths or Tulips is *Silene pendula compacta*, sown in July and not grown into over large bunches on a dry, poor soil. In planting all these low-spreading plants, care must be taken that they are not buried in the ground; a mere pressing on the surface will be sufficient planting, with a little fine soil just spread over their roots. A very small amount of roots seems to be sufficient to keep them in the best of health, a fact not to be wondered at when it is seen that dense cushions of them spread and hang over rocks sometimes several feet from the point where the roots are anchored in the ground. For carpeting among the dwarfier bulbs, such as *Scillas*, dwarf Tulips and Snowdrops, or rather for alternating with them in lines to cover the ground in winter, we have *Daisies* red, white, and pink, and the variegated *Bellis acubasfolia* (a single form of which, by the way, grows abundantly among the Grass here), and a very dwarf, floriferous, and double red kind called *Rob Roy*. But among the prettiest dwarf flowering plants for low carpeting in spring are the prostrate *Phloxes* amongst which *P. Nelsoni* is quite a gem, as, indeed, is *P. frondosa* and *P. reptans*; it is necessary to have these well prepared and grown into little patches. *Veronica repens*, *Omphalodes verna*, and *Gentiana verna* are also all suitable carpet plants among the dwarfest bulbs. Other plants might be named as spring flowering, but which could scarcely be classed as carpeting plants, such as *Iberises*, *Alyssums*, *Hepaticas*, and *Primroses*: these are more suitable for massing by themselves than for carpeting among bulbs. But there are numbers of plants which may be classed as non-flowerers suitable for carpeting the edges of beds among dwarf bulbs, or, indeed, among any bulbs. Of these there are the various hardy Sedums, such as *S. lydium*, *S. glaucum*, *S. corsicum*, *S. rupestre*, and the *Saxifrages*, such as *hypnoides*, *hirta*, *rosularis*, *pectinata*, *Andrews*, *longifolia*, and a pretty one called *capillipes*.

In order to have a good stock of all these plants at the right time, they ought to be increased by division in autumn or very early in spring, and planted in nursery beds on a dry bottom, and properly attended to as to watering and cleanliness until they form compact tufts that can be lifted with balls when required, or they may be increased by means of cuttings inserted about the end of October in sandy soil in cold frames, from whence they should be moved to nursery beds in spring, selecting some moist situation not over exposed to the sun, so as to grow them quickly into patches. For carpeting among Lilies, *Gladioli*, *Crown Imperials*, and other tall-growing bulbs, the same plants may be used and allowed to remain permanently in the ground; to this list may be added all the *Violas*, which amongst themselves include endless variety, and several of the *Mimuluses*; such kinds as *M. moschatus* and *Harisoni*, *cupreus*, and the larger hybrid sorts, make good carpeting plants on soil suitable for Lilies. The large-foliaged *Saxifrages* also come in well for this purpose, such as *S. oppositifolia*, and among the tallest Lilies *Saxifraga crassifolia*. These are plants which do not root very deeply in the soil and which in winter may be lifted with the spade in thin sods or patches, with a thin slice of soil attached to their roots, until the border or bed is dug or renovated, when they may be returned to the same place again.

Dublin.

PERMANENT PLANTATIONS OF CANNAS.

I AM pleased to find some of your readers giving us the benefit of their experience on this subject, as I believe that when it is generally known how easily Cannas may be grown, their culture will be undertaken by many who have hitherto been deterred by the supposed difficulties attending it. Those who are interested in this matter will feel indebted to Mr. Sisley (p. 36) for the list and description of varieties furnished by him. Referring to the question of permanent plantations of Cannas, I may state that the only reason I had for doubting the advisability of retaining them after the second year arose from the fear that, owing to the exhausting character of the plants the soil would become too much worn out to admit of their successful development. It is, however, evident that this little difficulty may be overcome, and I now think that by the exercise of a little judgment Cannas may be planted out to remain in one spot for an indefinite period. In the first place good drainage

would have to be provided; a row of drain tiles through the bed, with the necessary outlet, or a layer of rubble would make this part of the affair efficient. Then the soil would need some special preparation; in fact, the same care should be exercised as in making a Vine border. This may appear to involve a considerable amount of labour, but it must be remembered that Cannas last several years, and will need very little labour to be expended upon them afterwards. The work may also be best accomplished at that season of the year when there is the least amount of ground work to do, and the beds would be ready to be planted when required. In winter they would, of course, need protection, and some provision might be made for throwing off surplus moisture. In spring a dressing of soil might be gently forked in, and in the growing season thick mulchings combined with copious manure waterings, would insure their full and hearty development. One of your correspondents remarks, that when left in the ground the young growth is apt to get nipped by frost; some Hazel rods bent over and covered with mats would, however, effectually insure them against such a mishap. By adopting these precautions there would not be much danger of their perishing, and it would be a boon to many if they could be left in the ground for a series of years, thus obviating the necessity of annually propagating and planting. Portions of the pleasure grounds, which are necessarily bare in the summer, would thus be agreeably furnished without taxing in any perceptible manner either the time or resources of the ground. The system is worth a fair trial, and, if successful, would enable the grower of fine-foliaged plants to decorate his garden at little expense. The ordinary routine of summer bedding entails considerable labour and anxiety, and anything which will tend to lessen either the one or the other must be welcome alike to the amateur and professional gardener.

J. CORNHILL.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

The Paris Daisy.—This plant, which is, in reality, no Daisy at all, but a species of *Chrysanthemum*, is very popular about Paris, and is extensively grown there and in many other parts of France. To a casual observer it has rather a common appearance, the flowers much resembling those of the Ox-eye Daisy, but it associates remarkably well with many other plants. It is of such a wiry, enduring nature, that it will flourish and flower profusely in the poorest of soils, and in the hottest and driest of weather. It would doubtless be found useful in this country on parching sandy soils, where many of our flower garden plants refuse to grow well. In Normandy it is much prized as a pot plant, and finds a ready sale in rural towns for window and room decoration, for which purpose I have found it very useful. If kept growing on for several years in succession it assumes an arborescent form, and in this state it is very effective either placed in the centre of a bed, with dwarf-growing plants around it, or grouped with other flowering and fine-foliaged plants.—J. CORNHILL.

Hardiness of Primulas.—Allow me to add my testimony to the hardiness of Primulas, especially *P. japonica*. Not only did they stand well last winter with me, but they bloomed well in five whorls; they were in good material on a dry rockery, but not protected. *P. cortusoides*, *P. alpina marginata*, *P. viscosa*, *P. pulcherrima*, *P. minima*, *P. integrifolia*, *P. sibirica*, *P. acaulis rubra*, *P. farinosa*, and *P. denticulata*, all appear to be standing the present severe frost. I hope no one will be discouraged by a fear as to their hardiness; few plants are more hardy, if any are, and they are gems we cannot well spare.—J. WOOD, *Kirkstall*.

Euphorbia Lathyris.—The British *Euphorbia* of which your correspondent speaks (p. 36) is probably *E. Lathyris*, or the Caper Spurge, a plant which is common in some of our woods and thickets. It is an ornamental plant, and might prove a pleasing feature in both parks and gardens. I have never before heard it called Jacob's Ladder, which is, I presume, *Polemonium cornutum*.—E. JENKINS.

Stobea purpurea.—I can fully endorse all that "A. P." says (p. 36) respecting this beautiful Composite. In the spring of last year I rose a batch of seedlings which, when fit to handle, were potted, the larger ones into 6-in., and the smaller ones into 3-in. pots. In these they grew rapidly, and nearly all the plants flowered, but, being confined to pots, they failed to produce as many blossoms as they otherwise would have done. My plants have proved themselves to be perfectly hardy, and my old plant in the open border is, after the severe frost which we have experienced, as fresh and well as ever, having from six to eight breaks upon it, and what most indicates its hardiness is the fact that it was only transplanted a few weeks before the first frost of the present winter set in.—E. JENKINS, *Maida Vale*.

NOTES OF THE WEEK

Large White Lapageria.—The largest plant of this which we have yet seen is in Mr. Hanbury's garden at The Poles, Ware. It covers the greater part of the side of a span-roofed house, and flowers freely from May till February. It is planted in a raised bed over the hot-water pipes, and in the height of the season many hundreds of blooms have been counted on it at one time. Opposite this is a fine plant of *L. rosea*, and the two, when in bloom, produce a striking effect.

Seedling Amaryllises.—There will soon be a fine display of these in the Pine-apple Nursery. There is, indeed, a quantity in flower already, and there are 4,000 coming on in succession. They are set under stages or other out-of-the-way places, where they can be kept dry until they show bloom, when they are brought into lighter quarters, and are given plenty of water. Out of such a quantity of seedlings something which will be in advance of existing kinds may reasonably be expected.

Thysacanthus rutilans.—This fine old plant, though met with in most gardens, is seldom seen grown in perfection. In this state we found it, however, the other day in Mr. Hanbury's garden at The Poles, Ware. Plants of it, growing in 8-in. or 9-in. pots, were furnished with numerous branches, with bushy heads of large deep green leaves, and scores of long, streaming racemes of scarlet flowers. Placed on shelves or brackets, such plants have a charming effect for many weeks during winter, and, for hanging baskets, few plants are better adapted. The results recorded are effected by planting young plants in good, rich soil out-of-doors in summer, and lifting them in autumn. Plants struck from cuttings in spring are preferred to old ones, and the growth which they make, compared with those grown continually in pots, is surprising.

Bomarea oligantha.—This has been continually in bloom with me since July last, and its clusters of prettily-spotted, reddish-orange flowers are very handsome. It is a plant that is easily cultivated, only requiring to be kept free from frost. In brighter weather the flowers are much higher in colour than they are now, but they then last in perfection only a fortnight, while now they keep in good condition for a month.—MAX LEICHTLIN, *Baden-Baden*.

Viburnum lucidum.—I cultivate a shrub under this name which is now beautifully in flower. It looks like a robust-growing Laurustinus, but it has much larger and finer foliage, which is of a bright shining green, and quite uninjured by the frost, severe though it has been this winter. There is an evergreen sort, with thick, shining leaves, from North America, of which I do not now recollect enough to be sure of the two being distinct, or whether my specimen is the American sort or not. However that may be, I can assert positively that the plant in question is one of the finest shrubs for forcing with which I am acquainted, and, thus treated, it forms one of the most showy of plants about Christmas time, and, indeed, all through the winter months. There is also *V. rugosum*, a large, round, hairy-leaved sort, which is likewise evergreen. Some of the deciduous *Viburnums* are very fine, both in flower and fruit. Where, for instance, can one find a more charming bush, when covered with ripe fruit, than our wild *V. Lantana* or *Wayfaring* tree. Between Maiden Newton and Crewkerne this charming plant grows along the roadsides on the chalk in splendid style, so fine, indeed, that the wayfarer is often tempted to carry off a bunch of it.—JOHN SCOTT, *Merriott, Somerset*.

Poinsettias at Ware.—There has lately been in Mr. Hanbury's garden at The Poles, near Ware, one of the finest displays of *Poinsettias* which we have seen for a long time. The plants, consisting of fine specimens, each bear from twelve to twenty brilliant heads of floral bracts, and are well furnished with large, healthy, dark green leaves. Such results as these have been obtained in the following manner:—After the plants had done flowering they were put to rest, and early in summer, when they again broke into growth, they were shaken out of the pots and planted out-of-doors in a sheltered situation in well prepared ground. Here they were kept liberally supplied with water till the weather began to get cold in autumn, when they were carefully lifted, potted, and placed in a little heat, and shaded for a few days until root action had again taken place, when they were exposed to the light, and air was admitted to them freely. Under this treatment fine plants are produced, which from November onwards make a grand display in the conservatory. At lifting time, any plants which are rather straggling have some 6 in. taken off their tops, and these are inserted into 4-in. or 5-in. pots, which are immediately plunged in a brisk bottom-heat, where they quickly take root, and form compact little plants, which are very useful for room decoration. The mode of culture here practised might with advantage be followed in gardens where a good display is required in winter, and

the results would be infinitely better than those obtained from pot culture, viz., long single-stemmed plants, nearly leafless, and bearing but indifferent flower-bracts.

Primroses in Covent Garden.—Some out-door flowers seem to have survived the late severe weather; among these are Christmas Roses and the common wood Primrose. The former are to be found in flower in some of the London nurseries, and plants of the latter in full bloom are now offered for sale in Covent Garden Market.

White Clove Carnations in the Flower Garden.—These are grown largely by Mr. Hill at The Poles, Ware, as bedding plants. Young plants are used for the purpose, and these are struck from cuttings in autumn. They are wintered in a temporary wooden frame, and, thus treated, they are far more satisfactory in the flower garden than an over abundance of scarlet *Pelargoniums*, crimson Beet, and similar plants.

Daphne indica rubra.—I have a good-sized plant of this *Daphne*, on which there are from twenty to thirty good trusses of bright blossoms, that fill the house with perfume. So useful is this plant in this time of the year that no greenhouse should be without it.—J. W., *Llanstephan, Builth*.

Lachenalia pallida purpurea.—This is the name given to a handsome purple-flowered form of this useful winter-flowering bulbous plant, now in bloom in the Hale Farm Nurseries, Tottenham. Though not one of the showiest of the *Lachenalias*, it is, nevertheless, a useful variety.

Gesnera Cliftoni.—This is one of the best of the winter-flowering *Gesneras*. It has large, velvety-green leaves, with handsomely-fringed edges. Its flowers, which are produced in great, pyramidal trusses, are brilliant orange-scarlet, and contrast effectively with the foliage. We saw well-grown plants of it in a garden in Hertfordshire the other day, where it is much used for table decoration.

St. Paul's Churchyard Garden.—According to the "City Press," invitations have been sent out from the architect's department of the Corporation to firms conversant with the art of designing public gardens, inviting them to submit designs for the embellishment of the ground around St. Paul's Cathedral. The work will probably, it is said, include improvements of an extensive character, as well as some alterations regarding the outer railings. The scheme in its full details has not, however, yet been finally decided.

Staphylea colchica.—Flowering examples of this hardy shrub, shown by Messrs. Veitch & Sons, at South Kensington, on Tuesday last, attracted much attention, it being discovered that a most valuable addition had been made to our list of plants for winter forcing. Its leaves when forced are of a lively glossy green, and its flowers, which are produced in large trusses on every shoot, are of a waxy whiteness, like those of the *Taberose*. Besides being attractive on the plants, such flowers will be most useful in bouquets, much better, indeed, than those of the *Dentzia*. It is, as yet, comparatively scarce, but, when better known, it will doubtless be largely grown as a market plant.

Tulips, Lily of the Valley, and Squills.—These form unusually effective objects just now in Covent Garden Market; they are planted in 6-in. pots, and consist of about four scarlet Tulips, six spikes of Lily of the Valley, and a few plants of *Scilla sibirica*, among which are introduced small plants of *Adiantum gracillimum*. Baskets arranged in a similar manner make charming subjects for table decoration.

The French Government has conferred the Cross of the Legion of Honour on Mr. Martin J. Sutton, managing partner of the firm of Sutton & Sons, Reading, as a special recognition of the merits of the exhibits of that firm at the Paris Exhibition, and of the services thereby rendered to horticulture and agriculture. We should add that this is the only instance, we believe, in which this distinction has been conferred on any English exhibitor of seeds at any French Universal Exhibition.

Prizes for Vegetables.—Messrs. Carter & Co., High Holborn, announce the following prizes for vegetables, to be competed for during the year:—Thirteen dishes of vegetables (to be competed for on June 24), to comprise 12 Onions, 12 Carrots, 12 Turnips, 12 Tomatoes, 3 Cauliflowers, 50 pods of Peas, 6 Globe Artichokes, 50 pods of Peas (distinct), 50 pods of Broad Beans, 50 pods of French Beans, 12 Potatoes, 2 Cucumbers (dissimilar), 3 Lettuces (Cos or Cabbage). 1st prize, £7; 2nd, £5; 3rd, £3; 4th, £1 10s.; 5th, £1; 6th, 10s. Four dishes of Peas:—50 pods of Carter's Telephone, 50 pods of Carter's Little Wonder, 50 pods of Carter's Challenger, 50 pods of Culverwell's Telegraph: 1st prize, £3 3s.; 2nd, £2 2s.; 3rd, £1 1s.; 4th, 15s.; 5th, 10s. 6d. For the best fruit of Dell's Hybrid Melon (to be competed for Aug. 26): 1st prize, £3 3s.; 2nd, £1 11s. 6d. 3rd, 10s. 6d.

NOTES FROM KEW.

Stove Plants.—A very elegant and desirable bulbous plant is Hartweg's *Calliphurra* (*C. Hartwegiana*), a member of the *Amaryllidaceae* family. It has rather large globose bulbs, developing from two to four leaves about 8 in. long, with a compressed and channelled stalk; the blade is about 4 in. long and 2 in. wide, lance shaped, and of a deep green colour. The flower stalk is about 1 ft. high, terminated by about six blossoms, borne in an umbellate manner, 1½ in. long, funnel shaped, divisions slightly spreading, and pure white, the tube with a dash of green at the base. It is yet rare in gardens, though not a novelty, as it was first discovered by Hartweg in 1842 growing on the mountains of New Granada, and was, a few years ago, re-introduced in quantity by Mr. Bull. The scarlet-headed *Calliandra* (*C. hæmatocephala*) is a highly ornamental shrub, about 2 ft. high, though, in its native habitat, it frequently attains a height of from 30 ft. to 40 ft. Its leaves assume a bilobed character, each lobe being again divided into about eight pairs of leaflets 1 in. long. The flowers are produced freely in tassel-like heads, about 1½ in. across, consisting of thread-like stamens of a bright red colour, which, together with its elegant foliage, render it very attractive. The cerulean *Cypella* (*C. cœrulea*), a native of Brazil, is a magnificent *Iridaceae* plant, and it is to be regretted that its beauty, as well as that of its congeners, is so ephemeral. It has bold, sword-like foliage, 3 ft. high, and from about the middle of one of them peeps a cluster of flower buds, which expand consecutively, and are enclosed in a green-pointed sheath. The blossoms consist of six divisions, of which the outer three are the largest and of a deep sky blue, often blotched with a deeper hue; the inner three are twisted upon themselves, their tips are of a rich violet-purple, and the bases of a tawny yellow barred with chocolate. It richly deserves a place in every collection, and is, moreover, a plant of the easiest culture. Bojer's *Euphorbia* (*E. Bojeri*), a native of the same country and introduced about the same time as the well-known *E. splendens*, is far less frequently seen than that kind, though it has much richer coloured flower leaves, which are borne quite as freely. In habit, also, it strongly resembles it, having the same rigid, grey branches beset with sharp spines, from between each pair are produced the short, oblong leaves. It may be needless to remark that the same mode of treatment is applicable to both. The yellow *Barleria* (*B. flava*), an old introduction from Arabia, seems well nigh discarded too, as it is seldom met with, but it is, nevertheless, a very attractive plant, producing its bright yellow blossoms in succession throughout the winter. It is of slender growth, about 2 ft. high, with opposite elliptical leaves, and the flowers are borne in dense, terminal clusters, and accompanied by several sharp-pointed flower leaves. Another little plant remarkable for producing a continuous succession of blossoms is the Mexican *Tetranema* (*Tetranema mexicana*), which grows about 6 in. high, and has closely-arranged oval leaves, from the axils of which are developed numerous flower stalks terminated by a cluster of small Pentstemon-like blossoms mottled with purple and white. Sabine's *Strobilanthes* (*S. Sabiniana*) once more attracts attention on account of its numerous deep mauve blossoms, which are produced freely. *S. glomerata* has flowers very similar in size and colour, but it is of a spreading, horizontal habit, and its leaves are covered on both sides with silky, crimson hairs. The variety *speciosa* is a coloured improvement on the type, having larger and more deeply coloured flowers. Both are natives of the East Indies.

Greenhouse Plants.—Foremost in novelty and interest is Walker's *Ainsliea* (*A. Walkeri*), an extremely elegant little plant discovered a few years ago growing at a considerable elevation in Hong Kong; it is a Composite, though at first sight very unlike one, and nearly related to the beautiful South American *Mutisia*. It is about 1 ft. high, and has a woody stem clothed on the upper half with numerous narrow leaves, with a few sharp serratures at the margins. The flower heads are arranged in a loose racemose manner on an erect stalk, and consist each of about three flowers, with four narrow, pure white divisions curled in a remarkable way, and with a purplish red column of stamens rising from the centre of each. The green-leaved *Veltheimia* (*V. viridifolia*) deserves a passing notice; it is a capital plant for cool conservatory decoration during winter; it has numerous large deep green leaves wavy at the margins. The flower stalks rise from 1 ft. to 2 ft. in height, terminated by a dense raceme of narrow tubular blossoms 1 in. long, which are, together with the stalk, of a pale flesh colour, and very copiously marked with spots of a darker shade. This handsome plant comes from the Cape of Good Hope, and has been many years in gardens. *Tremandra verticillata* is another excellent plant. It has a neat habit and whorls of narrow leaves, from the axils of which a profusion of rich purple blossoms are borne on thread-like stalks about the size of a sixpenny piece. Resembling it in habit is *T. hirsuta*, which, at a glance, is recognised by the hairiness of its branches

and leaves, as well as by its rosy blossoms. Both were introduced many years ago from Swan River, and the latter is also known as *T. Hugeli*. *Banksia spinulosa*, from the same country, is a remarkable Protead about 2 ft. high, in habit much resembling a dwarf Conifer, as it has needle-shaped leaves arranged in the same manner. It produces dense erect cones of its curious blossoms of a deep orange colour. W.

PLATE CLX.

THE NEW WHITE HYDRANGEA.

Drawn by Mrs. DUFFIELD.

THE new white *Hydrangea*, the subject of our illustration this week, is of Japanese origin. It was introduced to the United States by Mr. Thomas Hogg, an American traveller in Japan, whose name is not new to our readers in connection with Japanese plants. In the summer of 1876, Messrs. James Veitch & Sons, of the Royal Exotic Nursery, Chelsea, were appointed agents for the distribution of the plant in Europe, which commenced in the autumn of that year. In the following spring (1877) this *Hydrangea*, under the name of Thomas Hogg, was exhibited at the shows and meetings of the Royal Horticultural and the Royal Botanic Societies, when it received a first-class certificate from the former, and a certificate of merit from the latter. Its pure white flowers, large trusses, the length of time during which it continues in bloom, and its perfectly distinct character, at once secured for it many admirers. It has also been well received on the Continent, especially in France, where it is cultivated not only in private gardens, but also as a market plant. *Hydrangea* Thomas Hogg is closely allied to the common *Hydrangea*, and it has proved quite as hardy as that invaluable old plant. The white flowers of this kind will be a welcome addition to the pink and blue ones, the ornaments of so many gardens in autumn.

HARDINESS OF HYDRANGEAS.

As regards the correctness of M. Sisley's note (p. 28) as to the hardiness of *Hydrangeas*, except in districts where the frost is very severe, I have little doubt, as I do not think that any of our *Hydrangeas* where fully exposed, are at all injured, although the thermometer has more frequently been below 20° Fahr. than above that point for some time past. But in spring, when the buds begin to swell, a slight amount of frost, especially if the sun strikes them early in the morning in a frozen state, will completely ruin all bloom for the season, while plants that have been checked by removal would escape by being later in starting into growth. It is, however, at present, premature to speak of the full effects of the frost, as I have a vivid remembrance of former severe frosts when many trees and shrubs that appeared to have escaped, and that looked fresh and green when thaw set in ultimately died, or were so crippled as to be quite disfigured, and unlikely ever again to become ornamental objects. In the present winter even ordinarily mild localities have had a full share of frost, yet, as regards its effects, I quite agree with "Cambrion" (p. 42), that the ripeness of the wood has much to do with escape from its effects, and whatever may be the opinion of others as regards the climate of France as compared with that of Kent or other southern counties, I am of opinion that although the average temperatures of the two might show but slight difference, the chance of thoroughly ripening the wood in autumn would be decidedly in favour of the most southern station, and consequently M. Sisley's plants would bear a degree of cold that might prove fatal to plants that had made their growth in a humid atmosphere. I find our *Camellias*, *Aralias*, and similar plants fully exposed, to be apparently but little injured; but the wind and frost that ushered in the new year have been far more destructive generally than the more intense frost that we had before Christmas, as the covering of snow greatly protected both tops and roots, and probably the latter are more susceptible of extremes of temperature than the former, as I observe that even the hardest plants did not regain their usual luxuriant aspect immediately the thaw set in, but only gradually as the frost relaxed its hold of the soil about their roots. JAMES GROOM.

Linton, Kent.

Best Late-blooming Chrysanthemums.—The following are well worth growing, viz., *Blaine*, *Fair Maid* of Guernsey, *White Venus*, *Fleur de Marie*, *Madame Martbé*, *Mrs. Rundie*, and *Bob*.—D.

ICE HOUSES AND HOW TO FILL THEM.

THE following description of a most durable and at the same time useful icehouse, together with the method of filling it, may perhaps interest some of your readers. I am of opinion that the best form for an icehouse is a perfect circle, or something very nearly approaching it, and my reason for this is, that, mathematically speaking, more can be put on a circular base than on that of any other form. A circular icehouse, too, can be filled more easily than any angular building. An icehouse should be substantially built of 14 in. brickwork, set in cement, upon a foundation of well-made concrete; the outer surface of the brickwork should be covered with asphalt to

as possible, up the sides, the ice is shovelled in, and here again men beat and ram it into a solid mass; this is continued until the house is filled as high as is practicable, care being taken that straw is built up against the brickwork as the filling proceeds, and that the ice is spread in thin layers each of which is well rammed. The top is then filled with bundles of straw, as is also the passage, in order to prevent the ingress of air. The doors should fit as closely as possible for the same reason. The accompanying is a sketch of such an icehouse as I have attempted to describe; its size, of course, will depend upon circumstances, but, as will be seen, the capacity of the one represented may be much increased without any addition to its height.

CHARLES DENNIS.

Southwark Park.

prevent the percolation of water to the inside; great care must also be taken that the drainage of the structure is perfect. To ensure this the floor should be concave, with a grating of large dimensions placed in the centre for the free passage of the water produced by the melted ice. Beneath the grating a well or cesspool must be constructed to hold any sediment that may find its way to it; from this well the main drain, which must be ample for the purpose, should be led. At about two-thirds the height of the building, a doorway for the purpose of filling and getting out the ice when wanted for use, should be fixed, and from this entrance a covered passage or corridor must be built with an outer door; outside this again a platform (f

Ice-house; ground plan; 1, asphalt; 2, passage; 6, platform.

stone or wood should be firmly fixed, the dimensions of which may be about 10 ft. square; this platform, however, may, if desired, be movable. The best position for an icehouse is some convenient place in the pleasure ground or the wild garden. If properly managed the building may be very nearly buried and the mound around it tastefully planted with trees and shrubs; the top and walls should be covered with various creepers, such as Clematis, Ivy, Hypericum, &c.; thus treated an icehouse really becomes an ornament rather than otherwise. When the season for filling it is favourable, the best ice for the purpose is that from 1 in. to 2 in. in thickness; this is carted and thrown up upon the platform; there men break it and pound it with heavy sticks bent at the end, or with any handy kind of club until it is broken quite small. Indeed, it cannot be too finely pounded, for the smaller it is the better it will pack and consequently the longer it will keep. Having placed about 1 ft. in thickness of straw over the bottom of the house, and, as far

EFFECT OF THE FROST IN THE RIVIERA.

A WRITER in the "Times," some few weeks ago, described the flourishing winter condition of the half-hardy shrubs and trees in the Riviera. Could he now cast eyes on the very vegetation he described so glowingly, I think he would see cause to modify his expressions. A frost of 5°, or 6° at most, with a keen east wind, has brought about the change. Vegetation has been unable to withstand it, and it has left too surely the marks of its track, which only the warm spring breezes can efface. It is chiefly the succulent plants and shrubs that have suffered. The *Datura cornigera*, the pride of the winter garden in kindlier years, has had its flowers and topmost shoots destroyed. Plants from 10 ft. to 15 ft. high, usually loaded in January with pendent, fragrant blooms, have barely a flower left to tell of glory departed. The *Ichromas* both have shared the same sad fate. *Sparmannia*, a native of the Cape, is but a wreck of its former self, wherever it has been exposed to the searching east wind. The *Salvia* have mostly lost their blooms; *S. verticillata* and *tomentosella* should have just now been bright with blossoms; the conspicuous *S. cardinalis*, another glory of the winter garden, has not a trace of flowers left. The *Malva* worths again, such as *Abutilon album*, *Achania Malvaricus*, and *Sphaeralcea umbellata*, are all scorched in the tops, and offer dried leaves and blackened buds in lieu of blossom and greenery. Still the grand old *Eucalyptus globulus* has weathered the blast, and many a spray of its singular blossoms is seen on the tops of the older trees. Young saplings, however, have suffered where they have been unsheltered from the blast. The fine blue *Solanum lanceolatum* is just now a mass of bright bloom; its big, downy leaves have doubtless served it for shelter, even in the open. One plant that has pleased me in the winter—a native, I believe, of the Cape—has held its own in the general ravage; I allude to the *Eriocapalum*, which does service as Box edging in the Riviera; it is in full bloom just now. When in seed, this Composite looks as if stuck over with little balls of cotton wool, as the name itself implies. *Tournefortia betonicum* has mostly lost its blossoms, but retains its leaves and stems uninjured. It is used as a thick hedge at San Remo to shut in our garden at the Victoria from the sea air. An old plant of *Echeveria metallica*, which has stood in the same place for years, has been sadly handled, especially at the junction of the leaf and the stem. *Linum trigynum*, usually a golden mass in the January garden, has not, I really believe, a flower left to expand, and the leaves are strewn the ground thickly. The young *Date Palm* look very uncomfortable, but will doubtless recover from the severe check. Such is the condition of the vegetation, as it presents itself to me, after the treatment it has received from the rude east wind.

PETER INCHEBALD.

San Remo, Italy.

Nettles.—I have read (p. 4) Mr. Harpur Crewe's protest against M. Lavallo's remarks respecting Nettles. According to my opinion Nettles are exotic plants, brought at some very remote period from Asia, and, like the Poppy (*Papaver Rhæas*) and many similar plants, follow man wherever he establishes himself, and are never found far from cultivated places. I think, then, that M. Lavallo's assertion in reference to the Nettle is correct. England being highly cultivated, it is not extraordinary that Nettles should be found here and there at some distance from habitations. The following is a curious incident respecting them.—While the Nettles (*Urtica dioica*, *U. urens*, and *U. pilulifera*) abound in all the other parts of southern France on the Mediterranean, I have not yet seen a single plant, either in gardens or elsewhere, at Antibes, Cannes, Nice, Mentone, &c.; it seems as if the climate of Lower Provence is unfavourable to their growth, a fact for which I am quite unable to account or understand.—C. NAUDIN, *Villa Thuret, Antibes*.

TREES, SHRUBS, & WOODLANDS.

RATE OF GROWTH AND QUALITY OF TIMBER.

I DOUBT if Mr. Baines' remarks in reference to this matter (p. 28) will be accepted as correct by those acquainted with the subject. Speaking of the quality of the wood of the Wellingtonia, Mr. Baines says, "I think there is but little room for doubt, unless the tree is an exception to all others of a quick-growing character, for, taking a broad view of the subject, quality, which may be set down to mean strength, toughness and durability, is present in proportion to the time required for its formation;" and again further on he says, "In fact, the natural laws which govern the development of vegetable life in the formation of woody fibre appear to point generally in one direction, which is that slow growth means comparative strength and durability." Now both of these statements are, to a great extent, calculated to mislead. Fast-growing trees are not always comparatively the most useless, nor do trees of the same species, like the Oak, for example, produce better timber when they are grown slow than fast. On the last point I may simply refer Mr. Baines to Lindley's "Theory and Practice of Horticulture," where he will find the matter physiologically explained; and also the Admiralty Test Tables, which prove that the fastest-grown Oak timber is the best by a good deal as regards strength, toughness, and durability. Now let us compare the different species of trees, and see how far Mr. Baines' statements hold good. Take the Beech, which in habit and rate of growth is very like the Oak; but it is well known that it possesses neither strength nor durability, and hence is not employed for building purposes, while the Spanish Chestnut, which grows about as fast again as the Beech, is hardly inferior to Oak for any purpose, and after a time hardly distinguishable from it; hence the much disputed question as to whether Westminster Abbey is roofed in with Chestnut or Oak, but it is generally considered to be the former. Next let us take the Laburnum, which attains its natural height in less than twenty years, and is a comparatively old tree at thirty years of age when it produces timber unsurpassed for hardness, heaviness, and fine, close grain, for which reason it is called the "Ebony of the Alps." The common Elderberry grows up like a rush, but the old wood of the tree becomes both hard and tough, takes a fine polish and is sometimes used as a substitute for Boxwood. I can testify from experience that a piece of Elderberry wood, some years of age, takes the edge off a knife about as soon as any kind of wood with which I am acquainted. The Gum Tree, to go a little further from home, is about the fastest-growing tree in the world, but it is, nevertheless, tough, strong, and durable, hence it is becoming one of the most popular of shipbuilding woods, and the same may be said of Teak, which is preferred to Oak for similar purposes. These are a few exceptions to Mr. Baines' statements that the wood "of quick-growing trees is light, spongy," and of little use. Mr. Baines has fallen into a common error in estimating the quality of timber by its rate of growth, which is but an indifferent guide either way perhaps, for much of the quality of timber depends upon the secretions formed by the tree and the mode of growth. The Scotch Fir in its native habitat and the Larch are not slower growers than some allied species, but their timber is far superior because of the resinous and other secretions which it contains, and probably the strength and durability of the quick-growing Gum tree is explained in the same way. These and other instances prove that estimating the quality of the timber of the Wellingtonia, or that of the wood of any other tree, by its comparative rate of growth alone, as Mr. Baines does, is fallacious. Had we not been well acquainted with the qualities of the Larch, Mr. Baines' remarks might have applied to it just as well as to the Wellingtonia, but in that case he would have been wrong, and there is no reason for supposing that his speculations regarding the Wellingtonia will turn out to be better founded. C.

BEECH TREES AND UNDERWOOD.

In this, as in some other discussions that take place on kindred subjects, I think there is little doubt that those who hold opposite views are both, to a certain extent correct. I am led to this conclusion through actual acquaintance with places where the state of the undergrowth under Beeches is as different as it well could be, being entirely absent in some cases, and in others as fair a growth as could be met with under other kinds of deciduous trees. The discussion, hitherto, has gone little beyond assertion, on the one side, that in such and such places undergrowth did well with Beeches overhead, and, on the opposite, that nothing did or would grow under these trees. I am acquainted with places where there are portions of wood confined altogether to Beech, large trees, I have no doubt, 150 years old, with no more room between them than is necessary for the main-

tenance of a healthy condition, and yet there is a fair under growth of Hollies, Rhododendrons, and Brambles beneath them, and I know other places where, even under single trees standing a considerable distance away from any others, no single living thing exists, not so much as a tuft of Grass, under them. In each case the cause is obvious; in the first the ground is occupied by a number of trees that in their early days have stood sufficiently close to prevent the development of the lower branches, leaving them with clean stems, and branches high up from the ground. Where the trees stood singly they have had from the first room enough to assume their natural habit, wide-spreading branches hanging almost down to the ground, and in summer clothed with dense foliage, which excludes light to such an extent that nothing, not even weeds, could exist underneath, and it is not uncommon to find the same thing occur under Horse Chestnuts and Turkey Oaks, where the branches of these have grown uninterfered with in a like manner. I have never seen anything to lead to the supposition that there is anything in the Beech more than in other deciduous trees which is injurious to undergrowth further than their dense shade, when fully developed, being such as to prevent other plants existing beneath them. As to the theory that the roots of the Beech exhaust the soil so much as to prevent anything living on the surface occupied by them, this is doubtless a mistake, as is evidenced by the Ash, the roots of which, as is well known, impoverish the soil to a greater extent probably than any other tree, and yet beneath it many kinds of undergrowth can be seen doing fairly; but the branches of the Ash are naturally much more erect than those of the Beech, and it is not nearly so densely clothed with foliage, consequently it admits more light to the surface under it, and to this cause I think it is evident that the difference is due.

T. BAINES.

— Referring to the discussion relating to shrubs under Beech trees, it appears that under certain circumstances both sides may be right. It is self-evident that under a well-developed Beech tree or clump of trees, with the branches touching the ground all round and the roots interlaced and wattled, as is usual with the Beech, no shrub or vegetation of any sort could succeed; but, if the Beeches be comparatively wide apart and on a deep soil, and if circumstances have caused them at some past period to lose their bottom branches, then, with trenching and other preparation, various evergreens will grow underneath them, such as Box, Hollies, Yews, and Rhododendrons, if there be no lime in the soil. It was, I think, under such circumstances that the late Mr. Rose, with the consideration and concurrence of the Duke of Roxburgh, first began to plant Rhododendrons under the Beeches at Floors, about 1857. Hundreds, if not thousands, were planted there in his time. Considerable, indeed, rank vegetation will be seen under Beeches in certain parts of the New Forest under similar circumstances, that is, where the trees are old and the branches and foliage high overhead. But an instance of a contrary character may be seen at Powerscourt, Co. Wicklow, where there is a fine clump of Beeches, consisting of about two acres in extent, at a spot which need not be particularised. These Beeches, from intention or neglect, have not been thinned, and the consequence is they are a mass of bare and lofty trunks, like the stems of Palm trees, with no vegetation whatever underneath except a thin, scanty Grass. Where I now am, however, can be seen many Beeches of great age with abundance of vegetation underneath them, but the branches do not reach by many yards the surface of the ground, and the trees are wide enough apart to admit air and a sufficiency of light. I have lately cleared away some very old Beeches, root and branch, and I must say that the root part of the labour was of a most difficult character. Blasting was impossible, the roots being like wattled work, and I am quite sure that before anything could be planted over them it would first have been necessary to deposit a sufficient depth of soil all over the surface; the digging of holes would have been quite out of the question within the radius of the branches. W. D.

Dublin.

The Canadian Poplar.—I am glad to see (p. 24) attention called to the merits of this tree, which I have long thought deserved to be more extensively planted than it is, especially in situations for which it is more especially adapted, viz., moist water margins and similar places. Even when planted in elevated or dry situations, it overtops everything else. I have in my "mind's eye" a belt of mixed trees that were planted about forty years ago, and the Canadian Poplar, as it is locally called, is nearly double the height of the other trees, of which a goodly proportion are Spruce Firs; the Poplar far outstrips them all both in height and cubic contents of timber. It is, however, as I have said, in damp ground that its rapidity of growth and inclination to produce timber is more especi-

ally remarkable. In such situations it is no unusual thing for trees that have been planted thirty or forty years to measure double these figures in cubic contents of timber. The timber, too, is not without value; but I do not fully endorse an old distich which speaks of it as outlasting that of the Oak under certain circumstances. There are, however, purposes for which it is very suitable, being almost incombustible. In Kent there has been of late years a great demand for it for the joists of Hop kilns, which, being exposed to the action of a hot charcoal or coke fire burning openly a few feet below, are necessarily much exposed to the risk of being burned down. Poplar joists are, therefore, much sought after. Boards of Poplar, as well as those of Willow, are also useful for insides of stone waggons or carts, where a harder wood is not so good, being liable to splinter during rough usage. There are other purposes to which Poplar wood may be turned to good account, but it is unnecessary to mention them here; suffice it to say that the rapidity of its growth is a sufficient reason for recommending it to be planted extensively by all who wish for immediate effect. Like your correspondent, I am at a loss to know the difference between what in some places is called the Black Italian Poplar and the Canadian. The latter I take to be identical with the Ontario, which is the name most generally given to the Canadian; but, of course, neither are to be confounded with the Lombardy, which, though ornamental, does not produce timber in anything like the proportion of the Ontario or Canadian. I have never seen the Black Italian and Canadian together, and have only met with them hundreds of miles apart and at intervals of many years. It is possible the two may be distinct.—A. RETIRED GARDENER.

Tree Roots and Dynamite.—Referring to the use of Dynamite for blowing up large tree roots (p. 534, Vol. XIV.), will Mr. Miller, of Clumber, be kind enough to describe the *modus operandi*, the charge of dynamite, how applied, and where procured? Application having been made to the local ironmongers without success in obtaining the article.—W. L. C.

Two Ornamental Weeping Trees.—I noticed lately, in the nurseries of Fisher, Holmes, & Co., Sheffield, a variety of the purple Weeping Beech, which appeared to me to be superior to other kinds. It is named Stevens' Purple Weeping Beech, and was raised by Mr. Stevens, of Coventry, not many years ago. The weeping habit of the tree is perfect, and reminds one of that of the American Weeping Willow. Another equally attractive subject is a distinctly weeping variety of the May Duke Cherry, which, when in flower or fruit, must be a pretty tree either for a lawn or shrubbery. The plants of it which I saw, and which were leafless at the time, were in the form of tall standards, and the shoots drooped as perpendicularly as those of a Weeping Ash. As to the bearing capabilities of the tree I cannot speak from personal observation, but I was informed that the tree in no way differs from the common May Duke, except in regard to its weeping habit.—J. S. W.

Eucalyptus amygdalina.—In speaking of the value of the Eucalyptus as a means of preventing malaria, it is stated in the "Daily News" of the 9th inst., that Prince Troubetkoy, who has paid much attention to the subject, has come to the conclusion that *E. amygdalina* is a more useful species than *E. globulus*, as the leaves of the former contain six times as much volatile oil as the leaves of the latter, and the growth of the plant is equally rapid. The Prince states that, at his villa in the neighbourhood of Rome, *E. amygdalina* has resisted the effects of a temperature of 6° below zero. Can this be correct? Is so great a degree of cold not unusual in the vicinity of Rome? The term zero is sometimes erroneously applied to the freezing point, or 32° Fahr.; can such be the case in this instance? If the *Eucalyptus amygdalina* can withstand a depression of temperature amounting to 38° of frost, the plant may with every confidence be extensively planted in this country.—P. GRIEVE, Culford.

Lilliputian Wellingtonias.—One is not surprised at sports originating either from seed or branch from plants that have been long in cultivation, and perhaps at some period crossed with other varieties, but it is not often one meets with distinct sports among forest trees such as may now be seen at the Handsworth Nurseries, near Sheffield, in the shape of not a dwarf, but absolutely a Lilliputian Wellingtonia, raised in the nursery from seed sent from California. This Lilliputian form consists of about a dozen trees, all propagated from the original seedling; they are some five years old, about the height of one's hand or little more, and as dense and close in habit as a small *Retinospora*, for which they might be mistaken until one stoops and examines them minutely, when the true characteristics of the Wellingtonia are observed, except that the roots are as close and prickly as those of a Juniper. I never saw such a sport before.—J. S. W.

PLANT HAIRS—THEIR FORMS AND USES.

BY PROF. W. J. BEAL.

COMMON in gardens is a plant called *Ageratum mexicanum*, the stems and framework of the leaves of which are slightly rough on account of large numbers of hair-like projections

Fig. 2. Curved Hairs on *Ageratum mexicanum*.*

along the entire surface. A small fragment placed under a moderate magnifying power reveals the structure of these beautiful and delicate objects as follows: The greater number of these consist of from five to twenty cells of different sizes and lengths placed end to end. Each hair or chain of cells is curved more or less, often into a complete ring, always towards the top of the plant. The end cell is blunt or rounded at the tip. Scattered among these are occasionally seen sharp-pointed hairs which are straight and much more slender (fig. 3).

Fig. 3.—Slender hair of *Ageratum mexicanum*.

Fig. 4.—Glandular hairs having two rows of cells.

Still less frequently may be seen larger and stouter projections (fig. 4) in which there are two rows of cells overlapping each other. The lower cells are three or four times as long as they are broad, while towards the top the transverse diameter is the greater. The top of the projection is capped with a single hemispherical cell which is filled with a mucilaginous substance. All the other cells are in a greater or less

Fig. 5.—Hair of *Ageratum*.

Fig. 6.—Hair of *Erigeron canadense*.

Fig. 7.—Stout one-celled hair on *Puccinia capillaris*.

degree transparent. They are filled with a liquid containing granules, which, under a magnifying power of 250 diameters, are often seen to move about in steady, flowing currents. Some of these glandular hairs (fig. 5) have but a single row of cells for the main portion of their length. Perhaps still other forms might be found which would be intermediate between some of these, showing more exclusively that they were modified forms of the same members. *Erigeron canadense*, a common weed, is clothed all over its surface with slender, rapidly-tapering hairs composed of a single row of cells. Many species

* The degree to which these figures are magnified is not given because of considerable uncertainty in most cases.

of *Helianthus* are covered with similar hairs. The surface of *Panicum capillare*, old Witch Grass, is covered with slender, one-celled hairs, which are straight and quite stiff for their size. The surface of a common *Physalis*, or Ground Cherry,

Fig. 8. Fig. 9. Fig. 10.
Hairs on surface of *Physalis*, Ground Cherry.

abounds in slender hairs composed of from ten to fifteen cells placed in a single row. Some of these hairs terminate in a sharp point, but most of them have, at the end, a round cell like a knob, full of a sticky substance. Occasionally a hair produces one or more branches, which may likewise terminate

Fig. 11.—Hooked hair on fruit of *Cirsium luteum*.

with a short point or a globular cell. The fruit of *Cirsium luteum*, Enchanter's Nightshade, is covered with rather stout one-celled hairs which have a hook at the extremity. The stems of the common Butter Bean of our gardens have a few

Fig. 12.—Hairs on *Malva rotundifolia*.

Fig. 13.—Sessile gland on same plant.

scattering hairs of similar structure, though they are smaller and much more delicate. The surface of *Malva rotundifolia*, Common Mallow, is quite harsh to the touch, on account of numerous rather stout one-celled hairs, one to six of which project from a conical protuberance. These stout hairs spread

Fig. 14.—Hairs on petioles of *Steironema ciliata*.

in every direction. Among the hairs are a few sessile glands capped with two quarters of spheres. The edges of the petioles of *Steironema* (*Lysimachia*) *ciliata*, a kind of Loosestrife, are fringed with hairs, some of which are short and simple, while others are much larger and irregularly branched

like a stag's horn. Each hair, whether simple or branching, seems to consist of one cell, made of several pieces fitted together. The surface of *Leersia oryzoides* and *L. virginica*, Rice-cut Grass, is well supplied with short, stout, one-celled spines, all of which point downwards. Several species of *Galium*, Bed Straw, are also supplied with hooks of a similar character. In these the base of each hook is quite broad and the point quite short. The under surfaces of the leaves and the young stems of *Aralia*

Fig. 15.—Hairs on *Leersia oryzoides*.

papyrifera, Chinese Rice-paper plant, are thickly covered with a woolly substance, which consists of immense numbers of one-celled stalks, each having at the tip six or more one-celled

Fig. 16.—Hairs on *Galium*.

arms or rays, which spread in every direction, like the spokes of a wheel. The common Mullein is covered in every part with a still more abundant supply of branching hairs. The main axis of the hairs has radiating arms at different heights

Fig. 17.—Hair on *Aralia papyrifera*.

along its length. The glaucous nature of Cabbage leaves and Plums is due to numerous small cells on the surface. The mealy substance on Pig Weed, or Lamb's Quarter, consists in

Fig. 18.—Branching hair on *Shepherdia canadensis*.

numerous capitate hairs. *Shepherdia canadensis* is a rather rare shrub growing about the borders of lakes and seas. The young stems and buds, and portions of the leaves, are rendered red or rusty on account of the large number of scales, each of which is held to the plant by a short stem. Figs. 18 and 19 show two of these objects. In fig. 19 there are several rays attached side by side throughout most of their length, while in fig. 18 there are but few rays, which separate at once

from each other. Between these two extreme specimens are found any number of intermediate forms. Much like the preceding are the star-shaped scales on the leaves of *Deutzia scabra*. There are many scales of a similar character found on most of our Ferns.

De Candolle, in his "Vegetable Organography," says of the hairs of plants: "Some are very tender, others very rigid, and most are of all the intermediate degrees. With regard to

Fig. 19.—Shield-shaped scale on *Shepherdia canadensis*.

their direction, some are vertical to the surface from which they spring; some more or less incline forwards; others more or less backwards; some are perfectly straight, others hooked at the point; there are several which are contracted, or which are interwoven with one another. As to their form, they are found as cylinders and very cylindrically-elongated cones. They are sometimes seen in the form of reverse cones; among those that are ramified they are found forked, with two, three, or a greater number of branches; or starred at their apex, or divided at their base into branches which seem as so

Fig. 20.—Star-shaped hairs on *Deutzia scabra*.

many distinct hairs re-united into bundles, having a common base." Sachs says, "The first indication of the formation of hairs occurs in the papillose protuberances of the epidermis of many petals, to which their velvety appearance is due. To the simplest forms belong also the root-hairs which grow from the epidermis of true roots or underground stems (*Pteris aquilina* and *Equisetum*), they are thin-walled bag-like protuberances of the epidermis cells which lengthen by growth at the apex."

The *Petunia* of our gardens is rendered sticky and unpleasant to the touch on account of one-celled glands raised on a stem of from two to seven cells. *Scrophularia nodosa*, the Figwort of our rich bottom lands, has numerous glands on its surface. These are composed of one, two, three or more cells raised on a short stalk. Some of the larger glands are more expanded into flattened spheres, and are much like those found

on our garden *Verbenas*. The gland of the garden *Verbena* consists of a large cluster of about thirty-five cells at the tip of a delicate stalk. The top of the gland is seen in fig. 26, and appears to have about thirty rays, and some central pieces of

Figs. 21 and 22.—Glandular hairs of *Petunia*.

Fig. 23.—Glands on *Scrophularia nodosa*.

Fig. 24.—Glandular hair of *Verbena*.

irregular shape. The lower surface of the gland, when it breaks off, shows two rings, one within the other. The inner is seen first, and on turning down the tube of the microscope the outer ring is seen. The gland is full of a purple substance.

Fig. 25.—Lower side of gland.

Fig. 26.—Top of gland.

Fig. 27.—Side view of glands on *Tomato*.

Fig. 28.—Top view.

Figs. 27 and 28 exhibit the four-celled glands of the *Tomato* plant. Each cell, as in many other cases, shows a nucleus and some of them one or more nucleoli. Besides the short hair and the gland of the *Water Melon* plant shown in figs. 30 and

Fig. 29.—Hair and protuberance on *Tomato*.

31, there are large numbers of other very long-jointed hairs. Figs. 32 and 33 show two hairs of *Phlox Drummondii*. Here the glands appear to be composed of four or more cells. Some

Fig. 30.—Short hair of plant of *Water Melon*.

Fig. 31.—Glandular hair of *Water Melon*.

Fig. 32.—Hair of *Phlox Drummondii*.

Fig. 33.—Hair of *Phlox Drummondii*.

of the glands of this plant consist of a single cell. Fig. 34, *a*, *b*, represent some of the smallest hairs on *Martynia proboscidea*. Besides a few of these small hairs, the whole surface

of the plant, including the sepals and petals, is thickly covered with glandular hairs, as in figs. 35, 36, 37, 38, 39. These glands, as do most glands of other plants to a greater or less extent, secrete a sticky substance, which is usually increased in quantity by irritation. From the end of the gland, when touched, may be drawn out a gossamer thread of some length. The pulling out of the thread exhausts the gland wholly or in part, and causes it to collapse or change its shape. Fig. 36 shows a gland from which such a thread has been drawn. The

hairs or spines are stout and point backward, as in *Galium* and *Leersia*, they serve well to hold up the weak plant as it rises among stouter objects. Fruit with hooked hairs is likely to be scattered by holding fast to animals. The bloom on a Cabbage leaf or Plum, and the thick hairs on plants prevent them from becoming wet on the surface. The shield and star-shaped scales on *Shepherdia* and *Deutzia*, and others may serve the same purposes as hairs. These delicate objects must protect the plant from injury on account of sudden changes of the weather. The advantage of the sting of the Nettle to the plant is obviously a means of self-protection. The function of glandular hairs in some cases is a great mystery. In the case of *Martynia* I found they caught immense numbers of small insects, and in some way seemed to suck out their substance. Small insects are found to a greater or less extent caught and held fast by the glandular hairs on all or most of the plants which produce glands. In his "Insectivorous Plants" Darwin, by experimenting, concludes that the glands of *Drosera* devour animal substances. The same conclusion is arrived at in the case of numerous other plants, as, for instance, some *Saxifrage*s, *Primulas*, *Pelargoniums* and *Pingu-*

Fig. 34.—Hairs of *Martynia proboscidea*.

Fig. 35.

Fig. 36. Glands of *Martynia*.

Fig. 37.

fruit of *Tecoma radicans* (Trumpet Creeper) has on its surface numerous sessile, cup-shaped glands of which Fig. 40 shows a vertical section. In damp weather, or when not exposed to very dry air, these cups are heaped full with a drop of glistening liquid in each. Besides these, on the surface are numerous spots (fig. 41) in which numerous cells are clustered into a circular form. From these we may find all gradations down to a two-celled stomate, as in fig. 42. On each margin of the petiole

Fig. 41.—Spot on fruit of same.

Fig. 42.—Stoma on fruit of same.

culas. The glands of the Trumpet Creeper are active, even till the fruit is of full size are quite near maturity. They are much visited by flies, wasps, and especially by ants to such an extent that the plant is often considered a nuisance when placed near the house. The glands on the leaves of Cherry trees and *Viburnum* are also much frequented by insects. The base of the leaves of the Sunflower, Locust, *Pteris aquilina*, and numerous other plants are freely visited by insects; but of what benefit it can be to *Tecoma*, *Pteris*, *Helianthus*, and the Cherry to be thus visited is beyond my certain knowledge. The glands

Fig. 38. Tips of Glands of *Martynia*.

Fig. 39.

of *Viburnum Opulus* (fig. 43) and *Passiflora* are some cup-like glands, which exude a sticky substance. Similar glands are found on the petioles of the Cherry and some Peaches. For our present purpose enough of these hairs and glands have been described and illustrated. A large majority of plants possess something of this nature in a greater or less degree. When fresh, and especially when not exposed to direct sunlight or air which is too dry, these glands are covered with a spherical glistening drop which is often several times the diameter of the gland. The uses of these hairs and glands we probably now understand to some extent, but in other cases we

Fig. 40.—Gland of *Tecoma radicans*.

can only guess their office. The slender-pointed hairs may serve to some extent to ward off insects. These and the scale-like hairs may prevent the delicate surface from being scorched by the sun. This is not very probable, because most of the hairs on leaves are on the under side away from the direct rays of the sun. In the case of the common Mullein, the thick branching hairs probably make the plant offensive to cattle and other animals. In a similar way other plants are protected from animals. When packed within the bud scales during winter, the young leaves and flowers of many of our trees and shrubs are well protected by these soft hairs which envelope the tender parts like a mass of cotton or wool. After expansion of the buds these hairs generally drop off. When the

of Tomatoes, Tobacco, Petunia, and many other plants secrete a substance which is offensive to most insects and other animals which might otherwise devour the plants. Mr. Darwin has also shown that some of these plants do certainly absorb and appropriate gaseous and liquid bodies. Many ingenious experiments were made on plants of several different Orders, showing that "they detect with almost unerring certainty the presence of nitrogen." Plants by their glands were fed with Green Peas, raw meat, a decoction of Grass leaves. These substances "are acted on in exactly the same manner as by gastric juice." Why may not these glands also draw nourishment from the particles of dust which fall on them from the air, or from the particles of soil which in many cases accumulate to such an extent as to completely cover some portions of the plant? As root hairs are active in absorbing materials from the soil including something from solid substances, why should not these active glands absorb materials from the dust and fragments of soil? The free presence of the air and light may also assist in this supposed action. This covering of the plant by the particles of soil held by the hairs and glands may also save the plant from destruction by animals. Of one thing I am certain that these delicate objects are interesting to study. Situated as they are in immense numbers and in such great variety on the surface of so many plants, they are easily obtained and easily prepared for examination. They are excellent objects for a beginner in the use of the compound microscope; and for protracted and careful experiments, they are worthy the skill of the most accomplished scientist. In them we may spend weeks to advantage in observing the develop-

Fig. 43.—Glands on petiole of Snowball tree.

ment of cells, the nucleus and nucleoli, and the gyration of the sap. In form and colour they are exquisitely beautiful, while in variety they are inexhaustible.—“American Naturalist.”

GARDEN DESTROYERS.

THE PEA WEEVIL.

(BRUCHUS PISI.)

It is somewhat a matter of doubt whether this insect is really a native of this country, as it is frequently imported in Peas and Beans, but it is not a question of much importance to the horticulturist, as it has been thoroughly naturalised with us for many years, and its destructive habits are unquestioned. All gardeners have been troubled with what are commonly called worm-eaten Peas. These seeds have suffered from the attacks of the grubs of this insect, or a very nearly-allied species of the same genus (*Bruchus granarius*) the Grain Bruchus. At times the amount of damage caused by these grubs is very great, nearly every Pea or Bean containing one. Peas and Beans of all kinds, and the seeds of various leguminous plants, are liable to the attacks of these weevils. As the grubs generally avoid the vital part of the seed, those that are thus eaten will frequently germinate, but the plants from them are sickly and almost worthless. The remedies which can be used to destroy these insects are very few. The weevils are so small that it would be useless to search for them, and, as the grubs pass the whole of their lives within the Peas, almost any means of destroying them which could be devised would also injure the Peas. If a crop is so badly attacked as to be useless, it should at once be burned. Mr. Curtis suggests that immersing the Peas or Beans in oil would probably destroy the insects without injuring the vitality of the seeds. Others recommend submitting the seeds to a temperature of 150° Fahr. in an oven, which would probably kill the grubs without preventing the seeds from germinating, or to the action of boiling water for one minute immediately they are gathered, as the grubs are then just below the skin of the seeds, and would be destroyed without injuring the Peas. There are fortunately several small parasitic insects belonging to the ichneumonidæ which deposit their eggs in the grubs, carefully hidden as they are in the Peas. The little grubs from these eggs soon kill the weevil grubs, and in this way naturally assist in keeping down the numbers of these pests. The beetles are usually found in the spring and summer on various flowers; in February they may be found on the blossoms of Furze, in June on White Thorn, in July and August on *Spiræa* and *Rhubarb*. When the young Pea and Bean pods begin to grow the females lay their eggs on the pods opposite the seeds, and the grubs, when hatched, eat their way at once through the pods and into the seeds, which continue to grow, and, even if examined, do not show any external signs of injury, but on opening them a small grub will be found inside each, which feeds on the interior of the seed until little or none remains; it then assumes the chrysalis state, and in due course is transformed into the perfect insect, which, in the case of the Pea weevil leaves the seeds when they are fit to gather. The grubs of the Grain *Bruchus* generally remain in the seeds during the winter, the perfect insects making their appearance in the spring; in fine, warm weather, however, the transformations are more rapid, and the beetles sometimes emerge in the autumn. The grub before changing into a chrysalis forms a passage to the outer skin of the Pea, and probably gnaws that partially through in a circular ring, so that when the beetle, in its endeavours to escape, pushes against it it easily gives way. The seed should always be examined before sowing, when a spot may be found on each affected seed, which is rather less opaque and of a different colour to the rest of the skin; under this spot is the passage by which the beetle comes forth. Often the beetles are found dead in Peas and Beans which have been kept together in large quantities. This is probably the result of the insects being unable to leave the Peas on account of the door

Bruchus Pisi.

by which they would make their exit being in contact with other Peas, and so preventing the insects from escaping, or by the the skin of the Peas becoming so dry and hard that the beetle could not force its way out. The Pea weevil is about 2-10ths of an inch in length, and is black in colour, thickly covered with bright, brown, short hairs above and greyish ones below. The head is small and drooping; the antennæ have eleven joints, the four nearest the base being yellowish; the thorax is much wider behind than in front; the wing cases are considerably wider than the thorax, giving the insect a very broad and stout appearance. Each are marked with ten longitudinal lines or striae, and have a somewhat mottled appearance, caused by various pale dots and patches. The body is not entirely covered by the wing cases, but projects beyond in a somewhat sloping, triangular, terminal joint. The legs are strong, the hinder pair being considerably longer than the others. The Grain *Bruchus* is rather smaller than the Pea weevil; it is very similar in form but not quite so thickly covered with hairs. There are several slight differences between the two species, but it is needless here to dilate on them. The grubs of both species are whitish in colour, and rather more than 1-8th of an inch in length. Their heads are furnished with a strong pair of jaws. Their bodies consist of thirteen joints, and are fat and fleshy and rather curved. The chrysalides are whitish, the limbs of the future beetle being visible through the thin covering skin. S. G. S.

Destruction of Barn Owls.—While agreeing in the main with Mr. Harper Crew's remarks on this subject (p. 24) there is one point relative to the charge which he brings against sportsmen on which I must enter a protest. What may be done around Tring, one cannot say, but, as an old sportsman, and one who has shot over various parts of the country during more than a quarter of a century, I can most positively assert that I do not remember a single instance of a barn owl having been shot by anyone claiming to be a true sportsman. Besides, the barn owl does not [make its appearance until dusk, long before which sportsmen will have returned home. Gamekeepers will sometimes kill owls, as they destroy very young rabbits, but it is a practice which ought to be sternly objected to by their employers. I doubt very much, however, whether (as Mr. Harper Crew thinks) farmers do so. They, at least, are well aware of their usefulness in destroying vermin, and it is common in many parts to have a hole cut in the gables of barns and other outbuildings, in order to entice the owls to enter.—C. F., *Merlwood*.

THE LATE FROST AND ITS EFFECTS.

LIKE many others, I was extremely pleased to find, when the first thaw that came on Christmas Day had released many shrubs from their frost-bound condition, and freed them from their weight of snow, how little apparent damage had been done. A recurrence of frost, with nipping easterly wind, has now caused an amount of injury that has not been equalled for many years. Here, on the north-east coast, the thermometer never descended below 17°, thus marking only 15° of frost at the most; and, since the new year, only 7° of frost have been registered; but the violent and dry east wind has withered up many things that withstood the first frost. The greatest losses to deplore are the large bushes of *Veronicas* of the Hybrid Andersoni section, but Blue Gem *Veronica*, though much crippled, will recover; this has always been very hardy here; *Escalonnias* are sadly browned, *E. macrantha* and *rubra* being little injured; *E. mon-tevidensis*, Ingrams, and *pterocladon*, are killed to the ground; *Dracæna Veitchi* is but little hurt, and *Phormium tenax* has escaped with a browning; *Cornellia glauca* seems killed, and the broad-leaved *Myrtle* much injured, but the small-leaved variety is not touched. A few shrubs have proved themselves hardy even under these trying circumstances; *Pittosporum Tobira*, *Choraya ternata*, *Raphiolepis ovata*, *Desfontainia spinosa*, and *Aralia Sieboldi*, are quite uninjured. *Berberidopsis corallina* and *Viburnum Awakufi* have lost most of their leaves, but do not seem seriously injured; *Bambusa falcata* and *Chamærops Fortunei* testify to the severity of Chinese winters by seeming quite regardless of the cold they have lately endured; the Californian shrubs, *Fremontia californica*, and *Ceanothus aureus* look pinched, but will recover; *Ceanothus Gloire de Versailles* seems unhurt, but *C. thyrsiflorus* is dead; *Elaeagnus pungens* var., and the handsomest silver variegated form of the Japanese *Euonymus*, are uninjured, while the golden variety and the green type have escaped harm; *Arundo conspicua* is most remarkable for its endurance of bitter

east wind; its leaves are still green and fresh, while Pampas Grass and Tritomas are withered up or reduced to pulp. E. H. W.

St. Nicholas House, Sea-bro'.

— There is too much reason to fear that the latest visitation of frost has been productive of much mischief in gardens, and especially in the case of vegetables, as for several days bitter easterly winds prevailed, which seemed literally to scorch and dry up the leaves and young shoots of all plants to such an extent as to make many look as if dead. The frost before the end of the year, though intense, was accompanied by a quiet state of the atmosphere, and the snowfall certainly served, to some extent, to protect vegetation. The second visitation following so soon after the first one, with the intervention of but a few days of thaw and excessive rainfall, literally deluging the soil, found everything far more amenable to its influence than before. During its prevalence it has puzzled people to keep it at bay to protect houses, to keep it from Potato and other tender roots, to protect half-hardy shrubs and plants, and, not least, to find work for all hands to do. In many respects the frost has been productive of heavy losses, in other respects it may be productive of greater gain, so that the balance may be, after all, in our favour. A. D.

Effects of the Late Frost.—Mr. Gambleton's letter (p. 27) is very interesting but also very alarming. If he has already lost so much in his highly favoured locality, what are we to expect? I hope others will give us their experience in the same direction, but I would suggest that it is much too early yet to reckon up gains and losses. Three months more at least must pass before we can speak with any certainty. Many plants, now apparently dead, may be all right at the root and may shoot up again vigorously; on the other hand, many plants that now look unharmed may yet have had their constitutions so weakened as to be unable to bear up against a cold spring. My own opinion is that very little damage was done by the December frosts. The air was dry and there was little or no wind, but I fear this January frost will be very fatal; it came in after a very rapid thaw, and the wind has been strong and very cold. May I suggest to any of your correspondents who send accounts of their gains or losses that they give their addresses, if not their names. Such lists are of very little use unless we know something of the situation of the gardens in which the plants grow.—HENRY R. ELLACOMBE, *Bitton Vicarage.*

OUR NATIONAL COOKERY.

It is allowed on all hands that there is urgent need of reform in the cookery of England. It has been emphatically said that while the Powers above have provided us with the best materials, our cooks come mostly from a lower region. This does not, of course, apply to the mansions of the rich; there, with every expensive appliance, and a staff of thoroughly well-trained servants at high wages, it would be hard, indeed, if every meal were not a success. But all Englishmen do not inhabit palaces of plenty and luxury; many families must, perforce, content themselves with the imperfect performances of a "plain cook," while lower down in the social scale the ill-arranged dinners are prepared and served by an untidy "maid-of-all-work." What can these uneducated young women know of the true principles of cookery? They have had, in all probability, no opportunity of acquiring them; and yet the health and comfort of a family depend, in a great measure, on their unassisted endeavours. A "plain cook," questioned by an anxious mistress as to her capabilities, mostly replies, "I do not understand French dishes (?), but I can roast, boil, and fry." The roasting consists of putting a piece of meat into the oven, and basting it by fits and starts, when she is not otherwise occupied. The boiling is accomplished by immersing the luckless joint in a great deal of water, three times too much, and keeping it boiling at a galloping rate until it is served—ragged and unpalatable. "How, then, would you fry—a sole, for instance?" Nothing daunted, the cook replies, "Having wiped it, I put a little fat into the pan, and fry it brown." How pitiable! These evils have been endured in patience too long; that a reform is greatly to be desired has been felt by all classes for some time. Hence the establishment in provincial towns (to say nothing of the excellent cookery lectures at South Kensington and elsewhere) of schools of cookery. However, a long time must elapse before a knowledge of the subject can be universal; at present, it is confined to a privileged few, who are able and willing to avail themselves of these advantages.

It is, nevertheless, cheering to think that the matter has been taken up. It is said that the night is the darkest just before the dawn. The night of culinary ignorance was dark enough, Heaven knows, before any attempt was made to shed a ray of light on the gloom. It was very pleasant to me, some months ago, to hear a pupil of the South Kensington School lecture on a dish which she prepared

before the audience. She was a pretty girl of twenty, very appropriately dressed, with a bewitching mob cap, trimmed with cherry ribbons, and a muslin apron over a neat cotton dress. "I now proceed," said she, suitably the action to the word, "to gratinate my Cauliflower." When she had finished, the young lady lower down prepared a dish of "Carottes à la maître d'hôtel" (it was a vegetable day), detailing the process as she went on. This continued until the class, which consisted of six, had taken up their parables in like manner. They were listened to with great attention by the audience, which consisted partly of relations and friends, though there were many outsiders like myself. If the youthful lecturers appeared to be at fault, a real cook in the background was ready to set them right. These girls evidently belonged to an educated class, and had, no doubt, passed through the regular course which constitutes a young lady's training. They probably understood "the use of the globes," played the piano, perhaps the violin, and had acquired a smattering of one or two European languages. But that part of their training which I witnessed was by no means the least important. It was that which was to fit them to become good wives, active heads of households, patient trainers of ignorant, but, perhaps, willing servants; it was that part which, carried out fully, would teach them to make the most of a narrow income, and to diffuse plenty and comfort around them—the blessings of a well-appointed home. A writer of ancient days, describing a pattern matron, says: "She looketh well to the ways of her household, and eateth not the bread of idleness." If we turn to the condition of the labouring classes, their case is sad indeed, always excepting those families where the wife has been a well-trained cook in the service of affluent persons. Such a one will probably make the best of everything. Her husband will not forsake his clean, bright hearth for the noisy public house, nor her children be found perpetually on the dispensary doctor's hands for maladies brought on mainly by ill-cooked, distasteful food. With others the case is widely different. How often have I seen cottages, with gardens full of excellent vegetables, where the bread-winner was in the receipt of good weekly wages! but I knew that, through the incompetence of the wife, all was discomfort and bad management. "Much food is in the tillage of the poor, but there is that is destroyed for the lack of judgment," was written by one who had thought deeply on the subject many centuries ago, and it is quite true now. Let the educated among us take the matter in hand, it is well worthy their attention. Let them not disdain the humble duty of alleviating want by teaching thrifty, careful habits to their poorer neighbours. Let the wives and daughters of our professional and mercantile men spend some of their leisure in acquiring the principles of good cooking, we shall soon see a better class of cooks rising up among us, for the spread of culinary knowledge among mistresses will soon do away with idle and incompetent servants. One feature of the times is the appearance of a number of cookery books in a cheap form. My attention has recently been called to three written by Miss Orson, the superintendent of the New York Cookery School. The first is called, "A Cooking Manual, or Practical Directions for Economical Every Day Cookery." With this came two pamphlets, entitled "25-Cent Dinners for Families of Six," and "15-Cent Dinners for Working Men's Families." The first-named of these publications "is intended," says the authoress, "for the use of those housekeepers and cooks who wish to know how to make the most wholesome and palatable dishes at the least possible cost." "In cooking," continues Miss Orson, "this fact should be remembered above all others—a good cook never wastes; it is her pride to make the most of everything in the shape of food entrusted to her care, and her pleasure to serve it in the most appetising form." Her chapters on "Salads," "Vegetables," "Cheap Dishes without Meat," are truly excellent. What would the plain cook referred to in the beginning of this paper say to a "Mushroom pudding," or a "Carrot stew"? She would probably consider her mistress had taken leave of her wits, were she to order a vegetable soup without meat; yet we know that this dish often appears on the tables of the wealthy in France! The chapters on "Cookery for Invalids," and on "Bread" contain much information. The directions for marketing at the beginning of the book will be very acceptable to young and inexperienced housekeepers, indeed, older ones; may not disdain to take a lesson. The subject of marketing recalls to my mind the heroine of one of Charles Kingsley's novels who (the undowered daughter of an earl) marries a struggling literary man. She takes high views of a wife's duties and accordingly shortly after her marriage goes to market with her maid to purchase provisions for her small household. Her ideas on the subject of what was necessary were peculiar, as she came back with a woodcock and a head of Celery.

The 25-cent dinners are intended for the families of artisans, and I thought the preface, which contains an account of the nutritive qualities of different kinds of food, very good indeed. There are excellent recipes in every chapter for inexpensive but highly palat-

able dishes. That which treats of "Sunday dinners," contains directions for more costly dainties, such as "roast fowl," "à la mode beef," "rabbit curry," &c., these would disgrace no table. One thing struck me—the fowl was to serve for two dinners—the breast and thighs were to furnish the Sunday's meal, the drumsticks, wings, and neck, that of the following day. Let us hope that something else had been provided for the children, or that the dinner had been preceded by a very substantial lunch! When you come to the "15-cent dinners," you must not expect many luxuries, but there are different bills of fare for a week. Being ignorant of the prices of different foods in American cities, and also of the habits of working people there, I find it impossible to judge fairly of these *menus*. A few will suffice to quote. Monday—breakfast, boiled rice with scalded milk; dinner, corned beef and Cabbage; supper, Peas boiled in stock. Friday—breakfast, broth and bread; dinner, mutton and Turnips; supper, Barley boiled in broth.

Miss Corson rather discourages the use of tea and coffee on economical grounds, and hopes to see the time arrive when our working people will use broths and soups as substitutes for these stimulants. It is so difficult to alter the habits of a people, that I think it will be long before this change takes place. She strongly advocates the use of Maccaroni, which appears, from her book, to be sold at about the same price in America as it is here. Our working people are entire strangers to this valuable food, partly on account of its price, and partly because they are ignorant of any of the numerous ways of cooking it. I do not know what she means by saying that yellow maccaroni is better in quality than the white, as we know that the yellow colour is only given to it by saffron. These little manuals are sure to find favour with the educated from the scientific manner in which they treat the subject, and we hope that in this manner they will reach the class for which they are more particularly intended.

GARDENING FOR THE WEEK.

Stoves.

Climbers.—Where plants for draping the rafters, covering an end wall, or for using in any similar way, are employed in the stove, they should now be gone over and cut back sufficiently according to their kinds. This work is sometimes delayed until later on when considerable growth has been made, which is so far a mistake that the growth made has to be cut away, and is so much wasted from the energies of the plants, which naturally break weaker afterwards. In carrying out this operation it is necessary to proceed with discrimination, using the knife the most freely on the strongest-growing subjects, that soon extend so far as to injuriously encroach upon other plants. Strong-growing climbers, such as *Ipomœa Leari*, *Hexacentris mysorensis*, *Bougainvillea*, *Dipladenia*, *Aristolochias*, *Thunbergias*, *Clerodendrons*, and the large-leaved *Passifloras*, may be freely cut back proportionate to the size of the plants and the space they are intended to occupy, remembering that in all cases, the farther they can be allowed to extend, the more profusely they may be expected to bloom. Medium-growing climbers, such as *Combretum purpureum*, *Ipomœa Horsfallia*, *Jasminum Duchesne* d'Orleans, the double and single varieties of *J. Sambac* and *Manettias*, should not be so hard cut in.

Stenhanotis floribunda ought not to be cut back to any considerable extent at this time of the year. What pruning is necessary should be deferred until after the flowering, when all the shoots may be shortened in accordance with the space required to be occupied. Supposing the growth to have been well ripened during the preceding autumn, reduction of the shoots now will proportionately limit the ability of the plants to bloom.

Hoyas.—The twining species of these should only have their shoots shortened either at this or any other time of the year, so far as is necessary to keep them within bounds; for flowering, as is their natural habit, during a series of years from the same spurs, whatever reducing of the shoots is carried out in their case also limits the blooming. In cutting back all the above plants it is necessary for the operator to pay some attention to carrying the work out in a way that will admit of the production of young growth over the whole surface which is retained of the plants individually. This can only be effected by shortening the shoots to different lengths in place of, as is often done, cutting the whole back to something near a uniform length, the result of which is that nearly all the young growth made is from the point where they were shortened back to, leaving the lower portion of the branches devoid of fresh shoots, and, consequently, unable to bear flowers, of which it is desirable that an equal production over the whole surface of the plants should exist.

Fine-foliaged Climbers.—Climbers that are grown for the beauty of their leaves, such as the different species of *Cissas*, *Pothos argyrea*, *Echites nutans*, &c., should be freely cut back, so that the greater portion of the surface they occupy during the summer may be covered with new foliage. It may be well here to remark that the time of cutting in gives the best opportunity during the whole year for giving a thorough cleaning from insects. With these plants it is necessary now to do all that is possible to eradicate these pests, as from the position occupied when growth has fairly commenced there is less opportunity of dealing with them than in the case of non-climbers.

Hard-wooded, Fine-leaved Plants.—There is no greater mistake committed with these subjects than allowing them to get so tall as to be deficient of healthy foliage at the bottom, or in any way to exhibit old leaves wherein is an absence of the fresh, healthy vigour and colour for which they are grown. We often see plants like *Dracenas*, *Aralias*, *Brexia chrysophylla*, *Crotons*, *Capanias*, *Ficus*, *Terminalia elegans*, *Theophrastas*, *Spheroxygones*, and *Cyanophyllums*, in anything but a condition that makes them pleasing objects, for want of heading down when they require it. Now is the best time for this operation, in all cases allowing the soil to become somewhat dry before removing the head. With strong-growing species, such as *Spheroxygones*, *Theophrastas*, and *Cyanophyllums*, that possess a limited number of eyes, it will be found much better to leave from 2 ft. to 3 ft. of stem, cutting the eyes out from the top downwards to within 6 in. of the collar; this will force their breaking near the base, which will insure a handsome stem, well furnished with leaves down to the bottom, and, by leaving a considerable portion of the stem in this way, until the young shoot which is to form the future specimen has made some progress, it will materially assist the young growth, and avoid the chances of the cut-down plant dying, which sometimes results from the whole of the head and stem being removed at once. Plants treated as described should always be placed immediately where there is enough warmth to induce their breaking without delay, as, if kept where so cool as to retard growth, the inevitable loss of roots consequent upon heading down is certain to be further increased; to this frequently may be traced the death of the plants. The headed-down specimens ought to be syringed daily, taking care not to wet the soil too much until they have commenced to grow freely.

Gloriosas.—Where these plants are grown, either as trained specimens or pendent from a rafter, place the bulbs at once where they will start into growth, as they take a good time from the young shoots beginning to push to their arriving at a blooming condition, and it sometimes happens that when the growths are not made sufficiently early, it gets far towards autumn before they flower. It is better not to give them too much pot room in the first instance. I have found them succeed more satisfactorily by potting a second time than at once placing the roots in the fall body of soil they are to occupy.

Fern House.

Structures devoted to the cultivation of Ferns have usually at the present day more or less space so arranged that the plants can be turned out, giving them so far as possible a natural appearance. In the selection of the plants to be thus treated, it is necessary to keep in view the suitability of the kind chosen for the purpose, both as to their ability to bear shade proportionate to the position each individual plant will occupy by being overhung by others, and also to the size they will ultimately attain. It frequently happens that a want of consideration in this last matter much interferes with their well-being afterwards by some encroaching upon others, which either necessitates disturbance by removal, or a portion are so weakened by overcrowding that they ultimately die. The greatest mistake where Ferns are so grown is the introduction of too many large tree species that inevitably smother most of the weaker small growers and in a few years have not near enough space for their own development. When many specimens of large habit of growth are brought together in a comparatively small house, it not only detracts much from the individual beauty of each but destroys the effect of the whole; unless where the house is large and roomy in every way, it is better to have the tree kinds in either tubs or pots, plunged up to the rims in the beds where the smaller growers are planted out, by which means they can be kept within the prescribed limits, at the same time allowing them to develop sufficiently to exhibit their true character. Another advantage arising from their being grown in this way is that the position of any particular plant, or the whole of the large ones thus grown in tubs, &c., if need be, can be altered as occasion requires, either with a view to afford more room where it may be wanted, or to give a different appearance to the house where a continuous position held by the plants is somewhat monotonous. The present time, when most Ferns are at rest, or nearly so, is the most

suitable for any alteration required in the arrangement, as the smaller occupants which are planted out, some of which there would be a necessity for moving can be taken up and replanted where wanted without seriously interfering with their growth, which removal later on, when their young fronds have begun to push, is certain to do.

Insects.—Here also advantage should be taken of their dormant state to eradicate the insects most usually troublesome—brown scale and thrips. Scale is not easy to cope with on Tree Ferns that are planted out, and unless an attempt is made now when the insects are not increasing fast, and the fronds are in a hard mature state, which enables them to bear a much stronger dressing of insecticide than during the growing season, a deal of labour will need to be expended upon them in the summer. The eggs of thrips can, in like manner, at this time, be more effectually dealt with. The best way to proceed, that I have been able to find, is to dip the fronds singly in a strong solution of insecticide, allowing it to dry on, repeating the operation three or four times before the young growth commences to move; any old fronds that show signs of decay may be cut off, and in this way whatever insects are on them will be got rid of.

Orchids.

Cypripediums.—Many of the spring-blooming kinds, especially the varieties of *C. barbatum*, will shortly begin to throw up their flowers. They are much more susceptible of injury from water, even whilst the flowers are partially enclosed in the centre leaves of the crown, than most Orchids, yet I have seen them rot where, by watering overhead, moisture has been held for some time in the crowns of the plants, consequently, in giving it now it is well to be careful that none lodges in this way.

Trichopilia suavis.—This sweet-scented, early-flowering species will also shortly begin to push up its bloom spikes; appearing, as they do, at the under side of the pseudo-bulbs, it requires care in giving water to keep it from loinging about the flower buds. In the first stages of their development I have found them very impatient of moisture in this way, and it is best now to apply water with a spouted can, by which means, if the plants are potted as they ought to be, higher than the majority of Orchids, moisture can be got to the roots without endangering the bloom.

Dendrobium nobile and **D. Wardianum.**—Where a succession of the first named are gradually brought on to flower, a few more should now be put where they will receive additional warmth and a moderately moist atmosphere, giving little water at the root for a time. *D. Wardianum* that matured growth early in the season will now be showing flower buds prominently, and may have the blooming accelerated more or less in accordance with the time they are required in flower. As the flowers last long, where a successional supply is held in more estimation than a great display all together, it is well not to have too many in bloom at once, consequently, their introduction into warmer quarters must be regulated by this.

Flower Garden.

Auriculas.—With frosts and thaws alternating, it is difficult to know how to treat Auriculas just now. One thing, however, we do know, and that is that it is very dangerous to give any water to the roots. The occurrence of a few mild days showed us that many pots wanted water, and the temptation to give it was great, but, had we done so, the plants would certainly have been injured by the severe frosts which followed in a day or two afterwards. As the temperature seemed likely to fall to a very low point, we had some litter placed against the outsides of the frames, and a mat put over the glass at nights. It is scarcely necessary to remove the mats during the day time if the frost continue and the pots inside are crusted with it.

Carnations and Picotees.—These seem to delight in severe frost; still, when the thermometer threatens to fall down to zero, mats may be thrown over the glass. It is needless to mention that dryness at the roots is conducive to healthiness. Even if the day temperature should not reach so high as the freezing point, if air can be admitted it is as well to do so, as continued closeness of the atmosphere causes spot to appear on the leaves, and in this respect the plants are more liable to injury than Auriculas. Soil for potting ought to be prepared; good turfy, clayey loam answers best. The decayed turf should be torn to pieces by the hand, carefully inspecting it at the same time with the view of destroying all the wire-worms which it may contain. To four parts of loam add one of leaf-mould, one of rotten stable manure, and one of sharp sand, mixing all together by turning the mass over twice; it ought then to be stored in a dry place until it is required.

Dahlias and Hollyhocks.—While the weather is unfavourable for other work, stakes may be prepared. Those made of good Deal,

and painted green, last the longest, and look the neatest. The part underground, and a little above it, should be dressed with a composition of equal parts of tar and pitch laid on boiling hot; even charring the part of the stick that is to go underground tends to prevent decay.

Pansies and Pinks.—Those in beds will require attention during alternations of frost and thaw, as it is at such times that they get injured. Dress the surface of the beds with dry manure from a spent Mushroom bed, which is about the best material that could be used for preventing injury during changeable weather.

Phloxes in Pots.—Plants that were raised from cuttings, and that flowered last autumn, should now be placed, if possible, in a greenhouse temperature. Growth will thus be made earlier, and the cuttings can be taken off, perhaps, a month sooner than it would be possible to do if the plants were protected only by a cold frame. It is rather too early as yet to repot, but that operation might, nevertheless, be performed now, if it be likely that the pressure of other work would prevent its being done a month or six weeks later. The potting material recommended for Carnations answers well for Phloxes.—J. DOUGLAS.

Hardy Fruit.

In this department, the ground being still frost-bound, work has come quite to a standstill, at least, so far as the making, renovation, and top-dressing of borders are concerned. It is also too cold for any person to be expected to nail or prune, and no thoughtful person would desire any one to do such work in such inclement weather. There are sundry little operations which may, however, be done now with advantage, such as labelling any trees requiring attention in that way, cutting shreds for nailing, or preparing matting for tying, as the case may be; cutting and pointing stakes for newly-planted trees, preparing the necessary spring protection for wall trees, and repairing netting. The fruit-room, too, may be over-hauled, and all decayed Apples and Pears removed. Some of the latter that are specked are apt to become mouldy; these should be wiped with a soft, dry cloth. *Easter Bourré* is very subject to this mould, and, to keep it sound, it requires to be thus wiped several times in the course of the winter. *Josephine de Malines*, *No Plus Menris*, and *Easter Bourré*, are our best Pears at this date.—W. W.

Vegetable Forcing.

The severity of the weather makes this department of the first importance, for already large quantities of Broccoli are hopelessly damaged. Lettuces, Spinach, autumn-sown Onions, and all the Brassica tribe, look wretched, and the most must now be made of the means at command to fill the gap which is likely to occur in the supply. A hot-bed, consisting of three parts leaves and one of stable litter, should be made up for Potatoes, on which place frames, and plant the Potatoes at once in about 9 in. of light soil. *Fenn's Early Market* (round) and the old *Ashleaf Kidney* are the best kinds for the purpose. A similar frame should be put in requisition for *Early Horn Carrot*, and another for Lettuces, Radish, and Cauliflower. The demand for Asparagus is sure to be great, and fresh batches should be introduced to the forcing pit every fortnight. The crowns now start readily into growth, and a great heat is therefore unnecessary. A bed of leaves only is the most desirable forcing medium, as stable litter taints the Asparagus, especially when that material is used without due preparation, and the same may be said in reference to Rhubarb. If the crowns of these be now covered with Rhubarb pots, old tubs, or barrels, and a bed of leaves made over them, there would be an abundant supply till it could be had from the open air. Seakale is best lifted and forced in any dark, warm situation; a Mushroom house suits it well. It should be kept perfectly dark and not too warm or it grows thin or weakly. It may also be forced the same as Rhubarb in the open ground, but preference should be given to the system of lifting it. To keep up the supply regularly, fresh roots should be put in fortnightly. French Beans are always prized, and where there is proper accommodation for growing them they can be produced in abundance without much trouble. They should be grown in light houses or pits where a temperature of 65° can be maintained. They are best in 8-in. pots, which should have free drainage, and the soil should be light but made firm in the pots. A moist atmosphere is indispensable both for the well-being of the plants and to keep red spider at bay. Sow, to keep up the demand, at intervals of ten days or a fortnight. *Syon House* and *Osborn* are the two best kinds for pot culture; stick them with Birch twigs before they begin to flower, and never let the Beans stay on the plants an hour after they are fit to gather. Tomatoes (autumn-sown plants or cuttings) will now begin to grow freely and will require a warm, dry temperature of from 60° to 65° to set the fruit, after which, they may be freely supplied with tepid guano water, of which, if well

drained, they will take a liberal allowance. Pot culture and winter forcing of Tomatoes are not nearly so much practised as they ought to be. By many, no forced vegetables are more valued, and from the present time onwards are more easily produced. Lettuces and Endive under protection must be kept as dry as possible, or they will soon decay; Chicory and Dandelion help to eke out the Lettuces and Endive, and a few roots of these should be placed for forcing in the Mushroom house every two or three weeks. Mustard and Cress should be sown weekly.—W. W.

ANSWERS TO CORRESPONDENTS.

Conservatory Wall Plants.—Can you recommend me an ever-green flowering creeper to train over the trellised wall of a conservatory attached to the house and leading from the drawing room? The aspect is easterly.—F. B. T. [Try *Lapagerias* red and white, *Camellias*, and *Tacsonia exoniensis*.—S.]

Salted Walks.—What is the right way of using salt to cure weeds on salks, which all last summer were most troublesome, though frequently weeded?—T. P. [Apply the salt in spring when the weather is dry, and be careful not to let it go near Box or Grass edgings. The quantity is immaterial, but enough should be applied to cover the whole of the gravel.—S.]

Lapagerias and Slugs.—I am very much troubled with slugs eating my *Lapagerias*, and as both red and white come up very strong with me, it is disappointing to see them eaten through or even off altogether. Can any of your readers suggest a remedy? I hunt the slugs by lamp-light, and catch a great many; as all my plants are planted out, it is not easy to surround them with water troughs. Would green tree frogs do any good?—T. S. [The best protection we know of is placing zinc collars G. in high round the shoots, also wrapping wool round the young shoots inside the zinc.—J. V. & SONS.]

Substitute for Asphalte or Cement (p. 536, Vol. XIV.)—Asphalte and cement are expensive, and there is a cheaper substitute and quite as good, viz., coal cinders pulverised, or even ashes mixed with pulverised chalk and water. For many purposes these are better than cement. For covering walks, &c., they are lasting and cheap.—JEAN SISLEY, Lyons.

Two Best Melons.—“J. W.” who asked (p. 24) for information as to the two best early Melons, must have found him somewhat puzzled after reading the advice offered him by three good growers as to the sorts named. All three recommend different kinds, and no doubt all believe their varieties to be the very best. Why this diversity on a matter on which there might be expected to be unanimity? If any one had asked for the names of the two best Potatoes, one Kidney and one Round, probably every one would have said in reply, Ashleaf Kidney and Union or Early Market Round. There are six times as many sorts of Potatoes as Melons, and yet three growers recommend as the two best early sorts no fewer than seven different kinds. Why is this? Simply because one Melon is so much like another, in the first place; secondly, because most growers have their favourite kinds; and, thirdly, because some kinds will do well in the hands of one man and badly in those of another. The Melon is perhaps, of all vegetables, the most difficult to recommend. “J. W.” may say, “I cannot grow all the seven kinds, and how am I to select the two best?” One kind, at least (Read’s Scarlet Flesh), is twice recommended, and this is a special point in its favour; he may, therefore, well select this kind for one sort, and, if for a Green Flesh kind, he will grow Heckfield Hybrid or Victory of Bath he will not be far wrong.—A. D.

Rheums.—“W. T. V.” asks if Rheum officinale, of Baillon, and *R. palmatum*, var. *tanguticum* are synonymous. So far as concerns *R. officinale* and *R. palmatum*, they are specifically distinct, but as to the point of distinction between *R. palmatum* and the so-called variety *tanguticum*, I fail to detect any, though I have grown them side by side for the last few years, and, seeing that *R. palmatum* is a native of Tangut, I think it very probable that the only difference lies in the name: *R. officinale* may, at a glance, be distinguished from the old *R. palmatum* by the leaves having but very shallow lobes and by the inflorescence being more spreading, and the flowers arranged on the branches in a cylindrical manner, while *R. palmatum* has its leaves very deeply lobed; they are also much attenuated, the inflorescence is more contracted, and the blossoms are more loosely arranged. It is by far the most desirable of the two, from a decorative point of view, but both are stately plants and highly ornamental, specially adapted for planting as isolated specimens and also admirably suited for associating with other fine-foliated plants in producing a sub-tropical effect. Both attain a height of from 7 ft. to 10 ft. when in flower.—W. V.

Icehouses.—Will “S. D.” (Vol. XIV., p. 535) kindly tell me where the door ought to be, and whether two are required for packing between to keep out the air, &c.?—W. H. B. [There should be two doors, one at each end of the passage communicating with the pit or well; the space between them should be filled with straw or litter, closely compressed, to keep out the air, and in order to ensure this being done efficiently, it is always advisable when getting any ice out for use, to close the outer door before the inner one is open, as it is not so much the quantity used that diminishes the bulk, as the waste that takes place through a rise in the

temperature, when the outer air is allowed to rush in and displace that of the house. The whole secret of keeping ice is to so pack it around with straw, or other non-conducting material, as to maintain an equable temperature, and if this be done, and the body be sufficiently large, it is an easy matter to preserve ice the whole year through. I am acquainted with a place where they have a very simple and cheap way of keeping it, which is by having a large egg-shaped hole, some 12 ft. or 15 ft. deep, in a gravelly soil where there is plenty of drainage, and this hole except a yard at the bottom, is lined with clay well rammed so as to form a wall, which, before storing the ice is lined with straw in the ordinary way. The roof is made to look like a rustic summer house, by being covered with reeds, and managed in this way it answers the purpose well and is rather an ornament than otherwise. The advantage of a contrivance of this sort is that the first cost is light, but where this is not so much a consideration, a house built after the manner of the one described is by far the best and cheapest in the end, as, except the doors, it is imperishable. These should have good Oak or Spanish Chestnut frames, as those woods are, when in such a trying position of alternate wet and drought, more durable than any other, and the grain being close and solid they are not liable to fungus, so destructive to many other kinds of timber.—S. D.]

Boilers for Small Houses.—I should be glad to know where the boiler described by “A. D.” (p. 7) is to be obtained, whether it is heated by gas or coal, coke, &c., and whether it would be adapted for a house 25 ft. by 10 ft., with sloping roof from 7 ft. to 12 ft., not, what kind of boiler, or what tubular would be best for such a house, and, finally, what a proper boiler, tubing, and fitting would cost?—A. G. [The boiler in question is known as the Dome-top boiler; it is upright, round in form, has its ash pan at the base, lifting furnace door above, the fire enclosed in the water case, feeding door on one side of the top, and the flue on the other. It is specially constructed to stand in sheds or outhouses adjoining the house to be warmed, the flow and return pipes being carried through the partition wall; thus a certain amount of heat is given off in the shed that may be utilised in many ways, whilst abundance of heat is generated to keep the glass house well free from frost. Of course the heat so produced will be in proportion to the size of the boiler and the amount of fire required to heat it. A boiler of the size required by “A. G.” would cost about £35 15s., and would heat enough of 4-in. piping for a house of the size named. It can be got at the Thames Bank Ironworks. It is heated either by coal or coke, but the former is found to be at once the cheapest and most efficient. If, however, it is found that combustion is rapid, a mixture of small coke and cinders may be added with advantage after the fire is well burnt up. The entire cost of the boiler, requisite piping—that is, one flow and return—with fitting, would be about £7. The addition of another flow pipe would give more heating power, and add perhaps 25s. more to the cost. A special feature of this boiler is that as it needs no setting it can easily be removed, and is therefore specially acceptable to those who have short tenancies.—A. D.]

Names of Plants.—E. H.—The conclusion arrived at as to the name of the portion of pod set is rather unsatisfactory, but in all probability it is a species of *Mucuna*.

Questions.

Fruit Trees in an Orchard House.—Is it advisable to plunge in loam fruit trees in pots that are grown in an orchard house? or is it better to place the pots in the ground? What is the best liquid manure to encourage good fruiting? and when is it best applied?—J. E. W.

Plants for a Small Greenhouse.—What plants can I safely cultivate in a small greenhouse whose winter temperature varies between 33° and 40° Fahr., and which is not heated in summer? What I want are plants that would come into flower all the year round. The house contains a fine Black Hamburg Vine, which does not bear pushing on with heat. It is a lean-to against the northern wall of my garden; therefore, has a full southern aspect, and gets plenty of light.—J. E. R.

How can I best combine Fruit and Flowers?—We have the following houses and frames, viz., three successional Vineries with stages, one Mushroom house with little light, two Peach houses without stages, one hot and one cold, the Peaches being trained on the wall, and one house specially for flowers. This latter, owing to the water tank which heats the other houses, is too damp for plants like *Pelargoniums*. These houses are all lean-to; there are also numbers of frames hot and cold. What would be the best way of combining flowers for the house and conservatory all the year round, and bedding-out plants with the requirements of the fruit? Our difficulty has hitherto been that the flowers are sacrificed to the fruit, for, although we have all degrees of heat, we cannot at some seasons command sufficient light by bringing the plants close enough to the glass. Our present arrangement, which does not keep up a satisfactory supply of flowers all the year round, is to keep Ferns and flowers just coming into bloom in the greenhouse which kept at this best temperature; hard-wooded plants and those in bud in the warm Peach house, having little else in the Vineries than cuttings, seedlings, &c. As I know that this problem, how to combine fruit and flowers, is a constant difficulty in private gardens, will some of your experienced correspondents give us their advice as to what flowers, including cool Orchids, it would be best to assign to each house? Also if more glass is indispensable, what would be the best to put up?—A. B.

Spent Bark from Tanneries.—Can this material be utilised in the kitchen or flower garden? also gas lime, or urine?—IGNORAMUS.

SOCIETIES AND EXHIBITIONS:

ROYAL HORTICULTURAL SOCIETY.

JANUARY 14.

THE most prominent features of this exhibition were flowering and fine-foliaged plants from Messrs. Veitch & Sons, of the King's Road, Chelsea; collections of brilliant blooms of Zonal Pelargoniums, from Mr. Cannell; and groups of Primulas from Messrs. Sutton & Sons, of Reading.

First-class Certificates were awarded as follows—

Amaryllis Dr. Master's (Williams).—A kind with well-formed flowers of an intense orange-crimson, very distinct, and well worth adding to even small collections.

Staphylea colchica (Veitch).—A hardy shrub with white flowers, and of great value for forcing—to all appearance even superior to the much grown *Deutzia gracilis*. It is a plant which will, doubtless, be largely grown for supplying cut blooms at Christmas.

Primula Ruby King (Sutton & Sons).—One of the finest Chinese Primulas in cultivation. The habit of the plant is good, the leaves handsomely cut, and the flowers, which are produced in very large trusses, of a deep satiny magenta-purple, with a rich golden eye.

Cyclamen Reading Gem (Sutton & Sons).—A variety with handsomely marbled leaves and very large purple flowers with broad, pure white petals.

Miscellaneous Plants, &c.—Messrs. Veitch & Sons were awarded a silver-gilt Flora medal for a miscellaneous collection of flowering plants, amongst which were Roman Hyacinths, Tulips, Primulas, Carnations, Lilac Charles X., and the pretty *Crassula lactea* in pans; also fine baskets of flowering plants of *Daphne indica* and *indica rubra*. These were backed up by well-grown plants of *Yucca filamentosa variegata*, Palms, Rhododendrons, and Indian Azaleas. A cultural commendation was awarded to Mr. Cannell for an exquisite stand of blooms of Zonal Pelargoniums, the trusses of which, as well as the flowers, were large, and the latter highly coloured. Amongst others, the following kinds were worthy of special notice: Mrs. Leavers, brilliant rose; Lord Gifford, bright scarlet; Louisa, lilac-pink; Dr. John Denny, intense purple, crimson centre; Circulator, fine salmon; Lady Sheffield, deep rose; Lizzie Brooks, crimson suffused with purple; and J. C. Masters, purplish-crimson. Mr. Cannell also contributed plants of Primulas, the flowers of which were of a bright rosy-magenta, large, and well formed. Mr. B. S. Williams, of Holloway, contributed *Cymbidium affine*, a plant distinct in habit, form, and colour from any other kind; also well-flowered examples of *Mandevilla polydicta*, finely-flowered plants of *Sophronitis grandiflora*, growing on coral; and one of the finest varieties of *Odontoglossum Rossi grandiflorum* perhaps ever exhibited. Mr. W. Brown, Brent Nurseries, Hendon, sent finely grown plants of a white variety of *Primula sinensis fimbriata*, named Princess Louise; a deep rose-magenta kind belonging to the same class named *Exquisite*; also a handsome rose-coloured Fern-leaved kind, and a blue-flowered variety named *P. sinensis fimbriata cœrulea*. The same exhibitor likewise showed a group of *Solanums*, remarkable for their dwarf, compact habit and the abundance of brilliant scarlet berries which they bore. For these and others, a small silver Banksian medal was awarded. Messrs. Sutton & Sons contributed a striking group of Primulas, for which a large silver Banksian medal was awarded. Mr. Overhead, gardener to Sir H. Peck, Wimbledon House, contributed a distinct and charming variety of *Odontoglossum cirrhosum*, which was much admired. Mr. Parr, The Gardens, Harrow Weald Park, showed *Abutilon Yellow Prince*, a compact-habited kind, especially adapted to winter flowering. Its blossoms are of a lively lemon color and very distinct; also *Yasumia*, very free-flowering *Abutilon*, resembling Darwini. Messrs. Osborn & Sons, Fulham, exhibited an attractive collection of hardy berry-bearing shrubs. A fine basketful of plants of *Crassula lactea* was exhibited by Mr. Thomson, of the Crystal Palace. Seedling Poinsettias were shown by Mr. Sparry, of Brighton, but were considered to be no improvement on existing kinds. The exhibition of ornamental trees and shrubs by Messrs. Lee, of Hammersmith, full particulars of which were given in THE GARDEN (Vol. XIV., p. 571). The luminaria and atterid attracted much attention. Two dishes of Seakale were sent by Messrs. Veitch & Sons, one was named Fulham White, the other Lily White. The two kinds being thought by some identical, they were shown on this occasion to prove that they were distinct; the former appears to be coarser than the latter, and the tips of the leaves are rose, whilst those of Lily White are greenish yellow. A dish of large Mushrooms, six of which weighed 1½ lb. was exhibited by the Messrs. Pratt, The Gardens, Hawkstone, Shrewsbury.

Scottish Horticultural Association (Jan. 7).—Mr. John Sadler delivered a short lecture on this occasion on Fungi. He said that the Natural Order to which they belonged contained 1,000 different genera and 25,000 species. Fungi constituted one of the gardeners' and foresters' greatest enemies, where it grew in shady woods and mossy dells. Before their ravages the Potato, Turnip, and Wheat crops and roots of Conifers gave way and timber crumbled; even in the very air we breathe, in the water, food, and medicine which we use were to be found the germs of fungi in teeming multitudes. Their effects were sometimes very injurious, and at other times unspeakable benefits were conferred by their becoming Nature's scavengers. Allusion was then made to the Vine and

Potato disease, and to dry rot. A piece of wood was shown with mycelium running through it. Reference was then made to the aquatic forms of fungi, and of edible and poisonous Mushrooms; 700 different species were reported to be found in Britain. The common Mushroom (*Agaricus campestris*) was the principle fungus used in this country although excluded from Rome. *Agaricus oroides*, *A. prunellus* (or Plum Mushroom, which was used in Rome) and *A. annularis* were illustrated by diagrams, as were also the *Boletus edulis*, *Phallus*, and *Morchella esculenta*. The effects of *Agaricus nector* resembled those of intoxication, and the *Boletus Satanas* was also a dangerous fungus. The lecture throughout was illustrated by specimens and diagrams. Mr. McMillan, Broadmeadows, exhibited some fine trusses of zonal Pelargoniums and cut blooms of *Chrysanthemums* in an exceptionally fine condition. The latter numbered thirty-nine of the finest varieties which were planted out in a house to which they are removed about the beginning of October. The Pelargonium trusses numbered twenty-six, all remarkably fine for the month of January, the flowers being large, finely-formed, of great substance, and bright in colour. Mr. L. Dow exhibited Turnip tops which he used as a substitute for Seakale. Some observations on the weather by Mr. Burns, Thingwall, Berkenhead, were read, in which he stated that the most frost registered by him was 24° on December 25. A communication on the same subject was read from Mr. Hugh Dickson, Belfast, where the thermometer stood at zero on December 25.

LAW.

Right to Remove Hedge Briers.—At the Rugby Petty Sessions, a labourer named David Forster, of Brinklow, was charged with stealing a quantity of Briers, value £1, the property of the Duke of Buccleuch. Mr. Wilkes, solicitor, Coventry, defended. Evidence was given by Mr. Rose, gamekeeper, as to defendant taking about 150 Briers from All Oaks' Wood, and Mr. Superior, who said the Briers were sold to nurserymen and for Rose tree stocks. Mr. Wilkes raised a novel point, by saying that no offence had been committed against the Act under which the summons was issued, as Briers did not come under the definition of trees, saplings, or underwood, as set forth in the section, and it was no offence to steal them; and he called Mr. Bradford, farmer, who said Briers were of no value but a nuisance; and Mr. B. Fitter, farmer, said in his opinion Briers were hedge weeds, and not underwood, and he was very glad to get rid of them; and the former witness added that he had given defendant permission to take them out of his hedges. Mr. Wilkes said, in point of law, no evidence of *animus furandi* had been given. Defendant was fined £1 10s., including costs.—"Journal of Forestry."

Milk of the Cow Tree.—Alexander Humboldt remarks that among the many wonderful natural phenomena which he had during his extensive travels witnessed, none impressed him in a more remarkable degree than the sight of a tree yielding an abundant supply of milk, the properties of which seemed to be the same as those of the milk of a cow. The adult Indians would go each morning with their slaves from the village or station on the slope of the mountain chain bordering on Venezuela, where Humboldt made a stop, to a forest where the Cow trees grew, and, making some deep incisions into the trees, in less than two hours their vessels, placed under these incisions, would be full. The tree itself attains a height of from 45 ft. to 60 ft., has long alternate leaves, and was described by Linden as *Brosimum galactodendron*. The milk which flows from any wound made in the trunk is white and somewhat viscid; the flavour is very agreeable. Some time ago, on the occasion of M. Boussingault going to South America, Humboldt requested him to take every opportunity of investigating this subject. At Maracay the tree was first met, and he made many observations on its excellent qualities were daily tested in connection with coffee and chocolate; but there was no opportunity for a chemical analysis. Nor does such appear to have occurred till the other day when, among the many curious matters exhibited by the Venezuelan Government at the Paris Exhibition, there happened to be several flasks of this milk, and after a long period M. Boussingault has been enabled to complete his analysis of this substance. In a memoir laid before the Academy of France he states that this vegetable milk most certainly approaches in its composition to the milk of the cow; it contains not only fatty matter, but also sugar, caseine, and phosphates. But the relative proportion of these substances is greatly in favour of the vegetable milk, and brings it up to the richness of cream, the amount of butter in cream being about the same proportion as the peculiar waxy material found in the vegetable milk, a fact that will readily account for its great nutritive powers.—"Times."

Rogieria gratissima.—This is so tender as has been supposed. We are informed that formerly in the York Nurseries, this Rogieria used to be treated as a stove plant, but with such poor success that it was hideous to behold. It was then removed to a cool house and planted out, where it has done remarkably well, and has for the last three years or more been quite an attractive object. The temperature of the house where it is growing in winter is from 35° to 40° F. All this is done at artificial heat is just simply to keep out the frost in severe weather.—"Gardeners' Chronicle."

WE have great pleasure in being able to confirm the statement first made in THE GARDEN that Mr. John Sadler has been appointed Curator of the Edinburgh Botanic Garden.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

"TREES OF THE FUTURE."

Few trees have suffered more at the hands of their admirers than the Deodar (*Cedrus deodara*). Planted high and dry on mounds or in low and undrained positions it has too frequently paid the penalty of its fatal gift of beauty, and sunk into premature decline and death. For more than forty years has this tree been praised for its gracefulness and colour in its young state; forty years hence will it have the same reputation that it now enjoys? The principal charm of a full grown tree lies in its habit, whether it be tall and slender, or massive and spreading, as a Cedar of Lebanon; and it is the latter that we associate naturally with the Cedar; so I venture to ask the multitude, not the initiated few, is it generally known that the Deodar is not a tree of spreading habit? In its native Himalayan gorges it thrives where deluging rains alternate with sultry heat during the period of its growth, and under these conditions of shelter and moisture it shoots up with a lofty trunk and drooping tiers of adpressed side branches to a height of 150 ft. before it begins to form the branching, forked head characteristic of the Cedar family, but which it reproduces only on a very small scale. We have already in the Cedar of Lebanon a tree that is unrivalled in the grandeur of its branching head; and, unless the Deodar succeeds in resisting the stunting influence of winter gales, so as to assert its superior height and stature in mature growth, we shall have neglected one of the grandest trees in Nature, for a tree that not only is not more beautiful but is one that will only cometoreal perfection in the most sheltered valleys of Southern and Western England. A glance at some of the oldest Deodars, notably those at Kew and at Blenheim, will show how far a Deodar in an average situation falls short of the stature and grace which it shows in its native forests, and how on the other hand, the Cedars of Upper Gatton or of Warwick Castle reproduce, in the most perfect way, the grandeur of their growth on the slopes of Lebanon. The real wonder is that a tree that thrives in company with *Rhododendron arboreum* and other forms too tender for an English climate should have been found hardy in this country, and given us so much beauty in a young state. Before leaving the Cedar family, *Cedrus atlantica* deserves praise because it has shown itself to be a hardier tree in the north of England than the two preceding ones. On cold soils and in exposed situations, where those just mentioned barely exist, *Cedrus atlantica* makes a sturdy vigorous growth that will always render it welcome where variety is sought for, and bids fair to make itself a name among exotic trees that require neither coddling nor protection.

The next tree that occurs to me, in these erratic wanderings, is a native of the southern hemisphere, and differs so widely from those mentioned before that it has not yet attained the position to which it is entitled, although it was introduced at the end of the last century. I mean the *Araucaria imbricata*. This tree, from the breezy uplands of Chili, is the only representative of its family that can find a place in our gardens—a family that can boast of the towering Norfolk Island Pine and the equally stately Bunya-Bunya (*Araucaria Bidwilli*), the pride of Queensland forests. Here we have a tree that thrives equally well on the coldest and most exposed hillsides of the north, and on the warmer soils and situations of the southern half of the kingdom. All who have had the privilege of seeing it in its native country are loud in their praises, both as to the value of its timber and the stateliness of its port when old; and those who, in this country, have seen it at Dropmore, Belvoir, and other places where it has attained sufficient age and growth to judge it fairly, will acknowledge that, of all Coniferous trees planted in this century, this is the one that must bear the palm in years to come. Stiff and ungainly as a young seedling, skeleton-like and formal as a young tree, it is

the most perfect example of the ugly duckling of fairy story; but we have here a tree that becomes in mature growth an object of the highest beauty, whether we admire the Fern-like grace of its massive lower branches, or are astonished at its growth in the Chilean forests, where, in old age, the lower branches decay, and the top expands into the mightiest "umbrella" among Pines, with so level a head that, from a distance, the forest looks like a deep green lawn made by no mortal hands. Its power of withstanding violent gales is unrivalled, as it presents so small a surface to the wind, and thus it thrives where other trees are blown to pieces; but, like every tree, it has its peculiarities, and refuses to flourish where smoke at all taints the air, or salt spray can touch it, and is more at home on the exposed upland than in the level plain. Planters should beware of the male form, which, though handsome in early days, makes only a small, stunted tree, and never attains the proportions of the other sex.

If it be true that it is from California we have obtained the largest number of ornamental trees, *Cupressus macrocarpa* must certainly be mentioned as one of the most valuable from many points of view. Introduced about thirty years ago, it has the rare distinction of having proved itself in that short time more rapid and vigorous in growth in our moist climate than in the drier one it came from in California. On the windy heights of Porto Pinos that overlook Monterey Bay, where the headquarters of this *Cupressus* are to be found, it is a stunted wind-blown tree with spreading, horizontal branches and thickened trunk that tell of the barren soil and the fierce north-west wind, as well as the rainless climate against which it has struggled. Nourished by frequent sea fogs, long hoary Lichens hang beard-like from the leeward branches, and make a strange contrast with the rich green foliage of these groves now so sought after by pleasure-seekers, who here find a cool retreat from the inland heats of a Californian summer. In a position such as this, where the drifting sand whitens the ground this tree does not attain a greater height than 30 ft. or 40 ft. even in old age; but, growing as it does where no other tree could exist, it may well be imagined what a future must be before it for all seaside planters; and at a little distance from the shore, where, instead of a one-sided struggle for existence, it can spread out its branches evenly, what a beautiful tree it is! Its greenness of foliage, coupled with extreme rapidity of growth and beauty in a young state, have long since made it a great favourite in the south-west of England and Ireland, where already it surpasses in height its progenitors in Monterey Bay. Unluckily there has been a prejudice against this tree on account of its supposed inability to stand severe frost, because in the extraordinary winter of 1860-61 many young specimens were killed in all parts of the kingdom. Since then established trees have not suffered, and it may be confidently asserted that it is hardy in all but the dampest and lowest parts of the kingdom, as a tree that grows naturally on a dry soil will always be rendered tender by being planted where it is saturated with excessive moisture at the root. As a seaside tree on all parts of our coast, where protection can be given for the first few years of its existence, it is quite unrivalled, and as it bears clipping admirably it forms a valuable shelter from the wind when planted as a hedge, just as the hedges of the European Cypress afford shelter from winter winds in the south of France. To the slender grace of the Deodar and the stately grandeur of *Araucaria imbricata*, the spreading and yet delicate growth of this green Cypress forms a delightful contrast, and in combination makes the most charming foreground to the two former Conifers, a trio of most distinct and beautiful trees. There is also a variety that assumes a pyramidal form and makes an exceedingly handsome specimen in places where no Cedar or Deodar could thrive. In some form or other no garden should be without this tree, which, like our native Yew, accommodates itself to so many purposes, while it outvies it both in rapidity of growth and brightness of colouring. Even on the north-east coast of Yorkshire it seeds freely at a short distance from the sea, and numbers of young trees have been raised from its cones, thus showing its entire suitability to our climate.

The other Californian Cypress (*Cupressus Lawsoniana*) is so well known and universally planted as to deserve no further comment. It forms a columnar tree of glaucous colouring,

and thrives everywhere in these islands, but in old age it is not so bold and effective a tree as the former from what I have been able to gather. Its beauty in a young state, and its perfect hardiness, will, however, always insure its being largely planted.

E. H. WOODALL.

QUALITY OF WELLINGTONIA TIMBER.

THE wood of the *Wellingtonia gigantea* is considered utterly valueless in California. It is so brittle that it is said a tree will break off by its own weight when the bark, which is extremely thick and tough, has once been cut through all the way round the trunk.

E. H. WOODALL.

— It does not require much knowledge of timber for any one to see that the wood of *Wellingtonia gigantea* is comparatively worthless so far as durability is concerned, at least, if put to any of the present uses for which deals sawn from the different kinds of Pinuses are now in request. The grain of the *Wellingtonia* is short and brittle, as may readily be seen by the way in which its branches snap when touched or exposed to much wind, and wood of this character, even when fully grown, is neither strong nor lasting. It is not always, however, that the value of timber can be judged by its hardness or texture, as it often occurs that such as are soft and easily worked up fetch the best prices. Mr. Baines cites an instance of this in the Sycamore, the wood of which is in request for machine rollers, and I have known Alder in places sell uncommonly well for turning purposes, such as making toys, pill boxes, &c., as well as broom heads and similar articles. In wet land districts I know of nothing more profitable to grow than Alders and Willows, as, besides the latter being used for railway and waggon brakes, it is the only wood of sufficient lightness that will stand the battering of a cricket ball. Rapidity of growth, or the reverse, is not always an index of the hardness and quality of timber, as the Larch and Douglas Fir abundantly prove, for neither of these can be said to be slow growers, and yet their durability under the most trying circumstances is beyond question. So solid and full of resinous matter is the wood of *Abies Douglasii* that it is heavier, size for size, than that of any other Fir with which I am acquainted, and as to rapidity of growth, in favourable localities, where it can have shelter, it rivals the Larch, which, as every one knows, frequently makes leading shoots 3 ft. long in a season. So far as my experience goes, the Douglas Fir has all the good qualities of the Larch with the additional recommendation that it is evergreen, and therefore of greater value in pheasant preserves for these birds to roost on. At one time Spruce was much grown for this purpose, but of all Conifers it is the most worthless, the timber being short and brittle and liable to readily decay. Pinus Laricio and the Scotch Fir can neither be regarded as slow growers, and yet their wood is strong and durable; and the same may be said of many others of a similar character. It appears, therefore, that in this, as in most other matters, there is no rule without an exception. Of all rapid-growing trees the *Eucalyptus globulus* is said to stand at the head; and yet I have been told that in Australia, where the climate suits it so, as to ripen it thoroughly, its wood is of the hardest and most durable description, a fact which accounts for the name of Ironwood tree which it bears. Then again, take the Sweet Chestnut, which is almost equal to the Oak in durability, the heart being very close-grained, tough, and hard, and yet it is by no means a slow-growing tree when planted in suitable soil. Other instances might be mentioned, but the above are, I think, sufficient to show that some trees, at least, that are of rapid growth are greatly prized for their timber.

S. D.

— It is probable that at the time when Mr. Baines (in rashly undertaking to pronounce against the quality of the timber of *Wellingtonia*) advanced the doctrine that the quality (embracing the durability) of timber may generally be estimated by its rate of growth, he little thought of the array of non-supporting facts which "C" has cleverly served up for his consideration. Other instances might be adduced, but meanwhile I will content myself with a few remarks on the timber which gave rise to this discussion—that of the *Wellingtonia*. Respecting its durability, the whole evidence goes to prove it to be of the most lasting description. In an excellent article on "The Distribution of the North American Flora," which appeared in a contemporary last year. Sir Joseph Hooker, speaking of the durability of the Big-tree trunks when fallen, says: "The duration of the dead wood in the forest is very great. I rarely observed signs of rot in the fallen trees which I examined, whilst in similar forests in Northern California I saw gigantic trunks of Silver Firs forming mounds of rotten debris without an atom of sound wood, and this in two years after their fall, as I was assured. I had no date for ascertaining the length of time which any of the prostrate *Wellingtonia* (*Sequoia*) trunks which I saw may have lain on the ground, but Mr.

Muir has supplied me with a very crucial case. It is that of a prostrate trunk with no signs of decay in any part of it, which had been burnt in two by a forest fire, and in the trench between the severed portions of which a Silver Fir grew. This Fir was felled, and had 380 annual rings; therefore to estimate the time during which the *Wellingtonia* trunk had lain uninjured, we must add to the 380 years, the time it lay before the forest fire burnt it in two, and then the unknown interval between that time and the arrival of the Silver Fir seed." Thus its durability, one of the constituents of quality, is favourably settled. There still remain the other two components—strength and toughness to be disposed of. These I am afraid are foreign to the Big-tree timber; it is well known to be "frush," but not worthless. It is easily split, and is capable of taking on a good polish. Is there no use for such timber? Californians seem to think there is, for according to the article already quoted from, "No less than five saw-mills have recently been established in the most luxuriant of the Big-tree groves, and one of the mills alone cut in 1875 two million feet of Big-tree lumber; and a company has lately been formed to cut another grove."

GEO. SYME.

— The few kinds of trees which "C" mentions as affording evidence opposed to what I have said in regard to the timber of slow-growing trees being generally of better quality than that of those which form wood more rapidly, do not affect the question from a general point of view, such as that from which my conclusions were drawn. I am conversant with what bears upon the subject in Lindley's "Theory and Practice of Horticulture," and also with the Test Tables of the Admiralty, in both of which there is a good deal that clashes with every day experience. Take, for example, the slowly grown Oak timber produced in Herefordshire, and that of the same tree from the moist, deep-soiled valleys of Westmoreland, where the wood is formed so much quicker, and ask the opinion of any one who has had experience with the comparative lasting capabilities of each when used for a purpose that would afford evidence within a limited time, such as in gates, gate posts, park railings, or others of a like character, and I am tolerably sure what would be the reply. "C" misses his mark so far that he actually confirms what I have said when he instances the Liburnum and common Elder. It is quite true that both these reach their full growth in a comparatively short time, but when that time has expired, and the maximum of size has been attained, the rate of increase in the wood will still be found to have been slow, from the simple fact that the bulk in both cases is small proportionate to the time occupied in its formation. I was looking at the subject from a general, not from an exceptional, point of view, as I think was evident from what I wrote. Timber containing such an amount of resinous matter as the Scotch Fir and Larch are also both outside the question, and so is the *Eucalyptus* and Teak, both woods produced under very different conditions of soil and climate from ours. Home-grown timber alone is concerned in the matter, and to introduce anything beyond it is calculated to mislead. The question is, in reality, confined to *Wellingtonia*. Does "C" imagine that there are any considerable number of individuals whose observation and experience connected with the growth of timber generally in this country are such as to give weight to their opinions who have any belief that the timber of this tree will be anything above second-rate in quality as compared with that of other well-proved trees? To plant the *Wellingtonia* in limited quantities for decorative purposes is undoubtedly quite right, provided the positions chosen are suitable, which is by no means always the case, often completely the reverse; but those who plant it extensively with a view to the production of timber will not, I think, be much complimented for their wisdom by the generations which follow them, even if the tree continues to thrive for a lengthened period in this country, which, from what I have had an opportunity of seeing in many places, is doubtful.

T. BAINEs.

THE OLETHRAS.

THIS genus of Heathworts contributes to our gardens several highly ornamental shrubs, some of them being rarely seen although their cultivation is remarkably easy and their requirements readily met. The different species are spread over North America, through Central America to South Brazil, Japan, and Madeira. Many handsome kinds come from Brazil and Peru, several of which are not yet introduced to cultivation. All are shrubs or small trees with alternate, serrate leaves and pretty white blossoms borne in terminal racemes or panicles; they most delight in a sandy peat and tolerably moist position. The Japanese and North American sorts make beautiful objects in the front of the shrubbery border, the tip of nearly every shoot being terminated by showy flowers. The easiest mode of

propagation is by means of seeds, which germinate freely if sown in sandy peat and kept continually moist in a cool place; layering may also be resorted to, although a couple of years or more are often required before the layers are rooted sufficiently to allow of removal. Some of the sorts, too, throw up suckers which, when carefully taken up, make good plants in a short time. Cuttings of the half-ripened wood, inserted in sandy peat under a bell-glass and kept under shade, root readily in most cases. A great recommendation for the kinds hereafter described is that they are perfectly hardy in this country, with the exception of two or three which are specially mentioned as being tender.

The Alder-leaved Clethra (*C. alnifolia*) was the first of all to find its way to English gardens. In the first edition of the "Hortus Kewensis" Mr. Collinson is said to have introduced this species in 1736. Catesby's first volume was, however, completed in 1732, and in it he describes the plant as then flourishing in the open air at Hoxton. In a wild state it affects wet copes from Maine to Virginia, near the coast and southward. It grows from 3 ft. to 10 ft. high, and in July and August is covered with its handsome, fragrant flowers. The leaves, which are intermediate between wedge-shaped and oval in outline, are entire towards the base and sharply serrated upwards, prominently straight-veined and smooth and green on both upper and under surfaces. The racemes are upright, panicle, and the bracts are shorter than the flowers. Several plants, probably mere geographical forms of this and only differing from it in degrees of roughness, hairiness, &c., have, at various times, received specific names. Dr. Asa Gray, in his "Manual," says: "In the South are varieties with the leaves rather scabrous and pubescent, or white downy beneath."

The Woolly-leaved Clethra (*C. tomentosa*) is confined to the Southern States, and was sent to the gardens of this country from New Orleans by Mr. Drummond. It differs from the Alder-leaved Clethra in its young foliage and branches, the under surfaces of the older leaves, and the flower stalks and calyx being covered with hairy down. In cultivation it forms a small handsome shrub, and, towards the close of the summer, bears very abundantly its racemes of white fragrant blossoms. Its somewhat straggling branches are slightly tinged with red; the leaves, which are about 3 in. long, are dark green, almost glossy above, and hoary with whitish down beneath.

The Acute-leaved Clethra (*C. acuminata*), a tall shrub or small tree, is a native of woods in the Alleghanies, Virginia, and southward, and flowers in July and August. The leaves are oval or oblong-pointed, thin, finely serrated, and from 5 in. to 7 in. in length; in colour they are green above and pale below. The racemes are drooping and solitary, not in clusters; the bracts, too, are longer than the flowers. Mr. Lyon introduced it to this country in 1803.

The Panicle-flowered Clethra (*C. paniculata*), another North American sort, has a truly paniculate inflorescence, the upright panicle lasting a considerable time in full beauty. The smooth leaves are between lance-shaped and oval, and are serrated at the edges.

The Bearded-nerved Clethra (*C. barbiervis*) is a native of Japan, from which country it has been recently introduced to Continental gardens by Maximowicz. It has long, rather oval leaves which are somewhat wedge-shaped at the base, and sharply serrated at the edges. On the upper surface, they are covered with short and rough hairs; on the under, the nerves are hairy, the axis of the principal ones being bearded. The blossoms are borne in upright racemes or panicles, and the leaf-stalks and flower-stalks are covered with rusty hairs. This has proved itself in many places to be quite as hardy as any of the foregoing kinds, all of which are deciduous.

The Tree Clethra (*C. arborea*), being a native of Madeira, whence it was introduced by Masson in 1784, is not so hardy as any of the sorts already mentioned, requiring, indeed, the shelter of a conservatory for its successful cultivation. It is an exceedingly handsome, tree-like, evergreen shrub, and, when planted out in the bed of a conservatory, attains a height of 10 ft. or 12 ft. In pots, however, it is easily kept within reasonable bounds. The leaves are oblong, lance shaped, serrated, glabrous both above and below. The beautiful blossoms, which much resemble those of Lily of the Valley, are produced in spike-like racemes, arranged in panicles, from August to October. This most desirable shrub will grow in any spot from which frost is excluded, and, as a corridor plant, few objects would be more admired. There is in cultivation a form with variegated foliage, and another a miniature of the large-growing type.

The Oak-leaved Clethra (*C. quercifolia*) inhabits the neighbourhood of Jalapa, in Mexico, and has foliage similar to that of

some of the Mexican Oaks. It is a most beautiful evergreen greenhouse shrub, with deliciously fragrant flowers, and requires about the same treatment as the Tree Clethra. G.

GROWTH OF PLANTS UNDER BEECH TREES.

THE discussion on this subject in your columns, shows that there seems to be no subject on which men will not disagree. I think that out of a hundred men acquainted with woodlands, ninety-nine would agree in saying that to plant shrubs under Beech trees would be sheer waste of money. The character of Beech woods everywhere is hollowiness, and though in certain exceptional cases growth more or less vigorous may be found immediately under large Beech trees, it is generally accounted for by side light or air getting we l under the boughs of the Beech. There is no place where this question may be studied more profitably than in the New Forest in Hampshire. The undergrowth there is of course natural, and very profuse, consisting of Holly Butcher's Broom, Furze, Brake, Thorn, Honeysuckle, &c. The growth continues right up to the stems of the Oak trees, but in most cases disappears under those of Beeches, except where the branches are high and the stems bare. Holly and Butcher's Broom seem more tolerant of the shade than any other shrubs. On the other hand Walnut trees, a comparison between which and Beech trees began this discussion, are very troublesome when planted near garden ground, as they send their roots as far and are as exhaustive of the soil in flower or vegetable borders as Ash trees. SALMONICEPS.

— Allow me to say that here, Box, Yew, Syringa, and Mahonias, grow most luxuriantly under, and in many cases close to the trunks of the Beech trees, and fine trees they are too. H. W. WARD.
Longford Castle.

— We have some very fine old Beech trees here with the tops well interlaced, and underneath them is as good cover of Laurel as it is possible to have, interspersed with fine Hollies and Yew probably 100 years old—the Beech trees being 150 years old. I have just finished pruning the Laurels, our system being to take out all pieces of upright growth, letting only the flat horizontal branches remain, an operation which is performed once in five or six years. The soil being of very good quality, Laurels thus treated do well, and make one of our best preserves for pheasants, and when Beech nuts are plentiful and the ground covered with snow, wood pigeons flock in hundreds to feed on the nuts protected by the snow-bent Laurel branches. The Hollies and Yew are never as a rule reduced in size, being of comparatively slow growth, and they are not of a compact dense character like those exposed to a greater amount of light.

Killerton, Exeter.

JOHN GARLAND.

— May I crave space to add a few explanatory words on this subject? as it seems to me the real point of the discussion has become somewhat involved. What gave rise to the discussion was my contradiction of M. Lavalley's statement that underwood "throve and flourished" under the Beech, which I said was one of the worst trees in the forest for destroying underwood. I was thinking, at the time, of the misleading nature of M. Lavalley's statement and of the Beech as a forest tree, and my remarks were principally intended as a caution to planters who wished to keep up underwood in their woods without more attention than usual. I was not thinking of isolated Beech trees with tall and naked trunks in pleasure grounds, as appears to be the case at Floors, nor did I ever doubt or say that under such circumstances underwood would not grow; I knew better, and in proof of this I may point to my own statement in a paper that was written by me before this discussion took place, and published in THE GARDEN a month ago. In that paper, in speaking of woodland trees, I state that: "it is simply the dense and long-continued shade of the Beech that kills undergrowth, but that only happens when many Beeches are planted together. Almost anything will grow under the drip of the branches of Beech trees standing in the open park where light reaches the trunk all round. Between myself, therefore, and those who have furnished exceptions, so called, as to plants growing under Beech trees, there does not appear to be much difference, as their experience seems mostly to relate to cases where the Beech trees were thinly scattered on the ground. The question is Is the Beech a proper tree to plant freely where underwood is expected to thrive? and to which I answer, No. In going through a wood where the natural undergrowth is varied and abundant, if one comes upon a bare spot it is sure to be under the far-spreading and interlacing branches of a group of Beech trees. Underwood has once been there, and you may often enough see the remains of it, but it has perished. This is the kind of evidence upon which my assertions are based, and it has not been controverted. In the woods here the underwood, consisting of coppice wood of different kinds is plentiful enough, and the common Bramble renders

the woods in most places almost impassable, except where the Beech abounds, and there vegetation disappears altogether or nearly so.
J. S. W.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Viburnum lucidum.—The plant alluded to by Mr. Scott (p. 57) as *V. lucidum* is quite correctly named, but it is not recognised as a species; it is only a variety of the common *Laurestinus*. The true *V. lucidum* has larger and more leathery, roundish leaves than those of the *Laurestinus*. It should also be somewhat pubescent, as *V. lucidum* is sometimes known as *V. hirtum*. There is a fine variegated form of it, and it has affinity with, if not identical with *V. strictum virgatum*, &c.—all forms of *V. Tinus*. I should say the plant from North America, with thick, shining leaves, is *V. laevigatum*; if the latter be Mr. Scott's plant it will be quite smooth.—T. WILLIAMS, *Ormskirck*.

Variegated Hollies.—I discovered the other day a handsome variegated Holly in the forest of Needwood. It is a sport from a nearly smooth-leaved variety, of erect, pyramidal growth, and I think it an improvement on all existing varieties. The marking (a splash of gold occupying the whole middle of the leaf) is more brilliant than in the variety called Golden Milkmaid. It has also purple stems, which add considerably to its beauty. There are likewise many other finely-marked varieties in this quarter, some of which attain a height of 50 ft.—W. ELLIOTT, *Burton-on-Trent*.

New Forms of *Pernettya mucronata*.—Considerable interest attached to the new forms of *Pernettya mucronata* exhibited at a recent meeting of the Royal Horticultural Society by Mr. L. T. Davis, Ogles Grove Nursery, County Down, and to one of which, *P. mucronata lilacina*, which with two others, is figured in the current number of the "Floral Magazine," a first-class certificate was awarded. We are informed by Mr. Davis that these *Pernettyas* are the result of selection from several batches of seedlings, the first lot having been raised from *P. mucronata angustifolia* many years since. Those exhibited at the meeting above referred to were only a few selected from many varieties so produced, so varied, also, as to present almost endless shades of colour in the berries, combined with much diversity in habit of growth and character of foliage. Mr. Davis has succeeded in obtaining several very pretty varieties with pink and blush-coloured berries, and one almost pure white, that is white with a slight tinge of blush, and there is one distinct creeping type with distinct rose-coloured berries. In making a selection of varieties for distribution, Mr. Davis has paid as much attention to the free-fruited qualities of the plants as to the colour of the berries. The many uses to which these attractive shrubs can be put will naturally suggest themselves. They bear very pretty pure white, Heath-like blossoms, which remain long in perfection, and, from their thorough hardiness and their dwarf and spreading habit of growth, they are peculiarly fitted to play an important part in winter-bedding arrangements, as they can be lifted again in spring or in early summer with perfect safety, and may be kept to any height or dimensions by means of pruning, or the plants can be renewed as readily by cuttings or layers. A charming mixture for a winter bed might be provided by using these *Pernettyas* mingled with such plants as dwarf Box of different sorts, various forms of *Eucynoms*, *Retinosporas*, &c., and they are very effective as a front row to mixed shrubby borders, as an edging to a clump of shrubs, or planted for furnishing narrow borders. They might also be employed for dwelling house and conservatory decoration, though they are most at home in the open air. They are not particularly fastidious as to the matter of soil; they will succeed in any ordinary ground free from lime, but of course would be benefited by the addition of a little peat, leaf-mould, or light fibrous loam—ingredients not difficult to obtain; only in poor sandy soils should manure be used, and then it should be well decomposed. Complaints are sometimes made of *Pernettyas* not producing berries, and it is not at all uncommon to hear people say, "They don't bear berries with us." Mr. Davis finds there are breeds of *Pernettyas* that bear berries more freely than others. At Hillsborough several varieties, such as *floribunda*, *speciosa*, and some seedlings from *angustifolia*, never show a berry. The common form of *mucronata* is also a very shy fruiter, hardly ever showing a berry in the younger stages of its growth, and only a few at any time, while Mr. Davis states that very many of the new varieties he has raised are perfect masses of berries on plants only a few inches in height, and they continue to fruit bountifully year after year. It is said there is only one form of a white or blush-berried *Pernettya* in commerce, viz., *P. caudata*. This is considered to be a distinct species; it is a shy grower and not very hardy, indeed, more suited for a pit or cold greenhouse than for exposure in the open air.—"Gardeners' Chronicle."

NOTES FROM FROGMORE.

THE Royal Gardens at Frogmore are always worth a visit; even at this dull season of the year there is much to interest any one connected with horticulture, and many cultural hints to be gleaned. Frogmore is not remarkable for novelties, more reliance being placed on plants or seeds which have always given satisfaction than on new kinds which have not been fairly tested. Beginning with the fruit houses, we find pot Vines in profusion just showing their fruit, which will be ripe in March or April. They are grown without the aid of bottom heat, the plants being set on slate slabs surrounding a bed in the middle of the house. Other early houses of permanent Vines are being started, and Peaches and Nectarines are being brought on gradually. French Beans are grown in large quantities, both in shallow boxes placed on hot-water pipes at the back of the houses and in the borders of Vineries. For the latter purpose the seed is sown in small pots and afterwards turned out into the borders on ridges of rich loamy soil about 2 ft. apart. Perhaps thus early in the season this plan is no better than that of growing them in pots on shelves, but where such quantities are required as is the case at Frogmore shelf room could not well be found for them; and, moreover, the shelves near the glass are, through planting out the Beans, made available for Strawberries, the earliest of which are coming into bloom. Pine-apples of the Smooth Cayenne type are grown here in excellent style, the fruits being large, well formed, and weighing about 7 lb. or 8 lb. each or more. The Grape room is filled with fine clusters of Lady Downes and large quantities of Black Alicante, and West's St. Peter's are still hanging on the Vines for present use.

Seakale and Rhubarb are required in large quantities in the castle at Windsor, and every available space is now occupied by these esculents. Among other places turned to such account are the trenches round the Pine pits, into which fermenting material is put for supplying heat. The Rhubarb and Seakale are planted on the top of the manure, and the whole is covered by means of hinged wooden shutters. Similar places to these might, in many gardens, be easily made round plant houses, the heat being supplied through sliding panels in the walls of the houses, and if the shutters were made portable, they might be easily removed and replaced by glass lights during summer. The ends of Mushroom houses, too, near which the boilers are set make excellent places in which to force Rhubarb and Seakale. Asparagus is forced in low span-roofed brick beds, heated by hot water and covered with wooden shutters, and in this way good Asparagus is obtained from December onwards. Mushrooms, which are always plentiful at Frogmore are especially so now; they are grown in sunken houses, each of which has four slate stages, running round them one above the other, two or three beds are made up at a time as they become vacant, and by this means a good succession is always maintained. Buttons only are used, and these are cut in quantity every morning.

Plants are grown here chiefly for room decoration or for supplying cut blooms. *Salvias* are largely grown for the latter purpose, and also for furnishing specimens for antique vases in Windsor Castle, a purpose for which few other plants are so well adapted. They are struck from cuttings in spring and planted out in good soil out-of-doors in June. In September they are lifted and potted, and removed indoors as soon as the severity of the weather necessitates such an operation. They are placed in empty fruit houses or similar situations as near the glass as is convenient, in order to keep them dwarf and to prevent the leaves from falling off. The first to bloom is *S. splendens*; this is followed early in the new year by *S. Heeri*, and when this is nearly over—in March—*S. gesneriflora* comes into bloom, and thus a succession of useful flowering plants is maintained from November till April. *Eupatorium ageratoides* is well grown, and is excellent for vases, &c. Cuttings of it struck in May and planted out during the summer, their shoots being stopped several times, make fine bushy plants for lifting in autumn to flower at Christmas. The blossoms are valuable for wreath making, as they are capable of being twisted into any desirable form. *Habrothamnus elegans* is grown effectively in pots for decorative purposes. Plants of it are struck from cuttings in spring, potted into small pots,

and kept indoors till the weather becomes mild, when they are planted out in the open ground for the summer. Their shoots are stopped several times during the growing season, and in autumn the plants are lifted and potted in 6-in. pots, and placed in the greenhouse, where they become bushy and handsome, and bear a truss of blossom at the end of every shoot, causing the latter to arch in a graceful manner. Such plants are now coming into flower at Frogmore, where they are much prized for placing in vases and in rooms, or in the conservatory.

C. W. S.

NEW OR RARE PLANTS.

BAMBUSA HETEROCYCLA.

THE strange Bamboo to which Mr. Carrière has given the above name, was in the Japanese garden at the Paris Exhi-

Bambusa heterocycla; 1-13th of natural size.

tion. It is a quaint-looking plant, remarkable for the oblique rings in diverse directions. It has almost exactly the foliage of *B. aurea*.

W. B. HEMSEY.

SIR BERNARD BURKE, being for a long time in search of a pedigree with reference to the Findernes, once a great family, having a seat in Derbyshire, sought for their ancient hall. Not a stone remained to tell where it stood. He entered the church—not a single record of a Finderne was there! He accosted a villager, hoping to glean some stray traditions of the Findernes. "Findernes," he said, "we have no Findernes here, but we have something that once belonged to them; we have Findernes's flowers." "Show me them," he replied; and the old man led him into a field which retained faint traces of terrace and foundation. "There," said he, pointing to a bank of garden flowers grown wild, "these are Findernes's flowers, brought by Sir Geoffrey from the Holy Land."

PLANT CULTURE IN MARKET GARDENS.

POINSETTIAS.—During winter, these are the brightest-looking plants that come to the market. They are, however, rather more difficult to cultivate than most market plants, owing to their liability to damp off in a young state. Mr. Reeves, of Acton, is considered the best cultivator of Poinsettias near London, and he devotes several large houses to their growth. The plants, which are grown as dwarf as possible in 5-in. or 6-in. pots, are struck from cuttings taken from stock plants in May and June, and inserted in 3½-in. pots. They are then plunged in bottom-heat in a close, warm house, and after a week or ten days have elapsed, are examined daily to ascertain if any of them have taken root. When this is found to be the case, the plants are immediately removed from the bed and placed on side stages of the houses, as, if left in bottom-heat after having rooted, they are apt to rot off close to the soil; in this position they remain until they have filled the pots with roots. They are then hardened off a little and potted into 6-in. pots and placed in span-roofed houses in a light airy position, where they remain to bloom. The plants are potted in good rich, sandy loam and leaf-soil, kept well watered, receive abundance of air, are allowed plenty of space to grow, and in December, January, and February they form plants about 12 in. or 18 in. in height, thickly clothed with healthy green foliage down to the pot, surmounted by brilliantly-coloured flower bracts; and to see three or four houses, each 150 ft. in length, filled with Poinsettias, all in bloom at one time, as we find them in some of the florists' establishments near London, is indeed a sight, the brilliancy of which cannot well be described. The double-flowered kind is, at present, not much grown for market; but, when it becomes better known, its late-blooming qualities, together with the fact of its lasting in a cut state in perfection for several weeks, will doubtless gain for it extensive culture.

DEUTZIA GRACILIS.—This is one of the prettiest and easiest grown of market plants, and one which is cultivated by all florists who have the means of forcing it into bloom early. Plants of it are obtained from cuttings of the half-ripened wood or by burying the bases of old plants several inches deep in sandy soil. The cuttings are placed in small pots or pricked out in frames, and, when rooted, they are hardened off and planted out-of-doors in a border of rich sandy soil. Those which are layered are severed from the parent plants when rooted and treated afterwards the same as the cuttings. In the following spring, before they break into leaf, they are cut back to within three or four eyes of the base, and during the summer the soil between them is kept well stirred with the hoe and the strongest shoots are kept regularly pinched back. In autumn, if large enough for forcing, the plants are lifted and potted, and placed in a frame or a shed until wanted. They are then introduced a few at a time into the forcing house. Daily syringings and plenty of water at the roots quickly bring them into bloom, and after being hardened off by being placed for a week or so in a cool house, they are fit for market. When grown for furnishing bloom in a cut state, old plants are cut back close to the pots every spring—an operation which causes them to push strong young shoots from the bottom. These, if well ripened, never fail to flower profusely their whole length, and thus form complete garlands of snow-white blossoms.

SPIRÆA JAPONICA (also called *Astilbe japonica* and *Hoteia japonica*) is, without doubt, one of the best market plants ever introduced. It was for some time grown as a hardy border plant, and as such received but little attention; but

as soon as it was found that it would withstand forcing, it became a favourite market plant, its easy culture, fine appearance, and usefulness for window decoration, securing for it more extensive culture probably than that accorded to most other plants grown for market. As a rule, the roots are imported from France and Holland in autumn, and from Christmas onwards the market is kept well supplied with it in a flowering state. Heat and abundance of water at the roots while growing are essential to its perfect culture. Imported plants of it are by some considered indispensable, and for early forcing no doubt they are best, but that English-grown plants are equal in other respects is proved by the fact that Mr. Maller, of Tottenham, who cultivates from 5,000 to 6,000 plants of it yearly, grows them on his own land at Enfield, and more healthy and floriferous plants could not well be imagined. In spring, the old plants are parted, and planted out in good rich, moist soil in an open, sunny situation, where they ripen their crowns perfectly; they are taken up in the autumn, and firmly potted in 6-in. pots, kept copiously supplied with water at the roots, and as soon as the flower spikes appear the pots are placed in saucers in order to keep the roots perfectly moist. They are forced so as to come into flower from as early after Christmas as is possible until the end of May. Well-grown *Spiræas* of this class in the early part of the year fetch as much as 42s. per dozen, but, of course, as the season advances prices diminish considerably.

SPIRÆA PALMATA is also grown for market, but not in such quantities as *S. japonica*. It is, however, well looked after by some growers, and its puce-coloured flowers and Palm-like, deep green foliage render it a very desirable plant, and one which would, no doubt, pay for more extensive cultivation could it be grown with as little trouble as *S. japonica*. It does not, however, force well, as, if placed in much heat, it grows tall and lanky, and its blossoms are pale in colour compared with those grown in a cooler temperature.

ARUM LILIES.—Few flowers are in greater demand in the market at certain seasons of the year than those of *Richardia* (*Calla*) *æthiopica*, or *Arum Lily*. They are used at Christmas and Eastertide for church decoration, and growers strain every nerve to get in a large supply at those times, as they then fetch highly remunerative prices. Mr. Reeves, of Acton, is one of the largest cultivators about London of this so-called Lily, and he grows his plants wholly in pots, thinking it less trouble and altogether a better plan than that of planting them out-of-doors during the summer, a system practised by some cultivators. All young suckers that are found at the bases of flowering plants are removed and placed in shallow boxes, until they become established, when they are potted into their flowering pots, plunged in cold frames during the summer, kept well saturated with water at the roots, and moved indoors as may be required for forcing. Old plants from which the blooms have been cut are placed aside until their leaves have died down, when they are shaken out and all the toes, as they are termed, or fleshy lobes of the roots, are removed and placed in boxes to be subjected to the same treatment as that just described in the case of suckers. A few weeks before Easter Mr. Reeves has several houses full of these plants, and their thousands of unexpanded, spear-like heads form an interesting sight; but to see their white, trumpet-shaped blossoms fully developed is, to say the least of it, a grand spectacle. *Arum Lilies* in 5-in. pots, with two or three heads of bloom fetch from 12s. to 20s. per dozen early in the season, but later on they are sold at a much cheaper rate. *Richardia maculata*, another

Arum Lily, is fast gaining popularity as a market plant. Its leaves, which are spotted with white, are equal to those of many of the *Dieffenbachias*, and the flowers, though not so large as those of *R. æthiopica*, are, nevertheless, quite equal to it in every other respect. This variegated kind requires a little more heat than the green-leaved sort, and it cannot be forced quite so readily. It is, however, an excellent room plant, and good dwarf plants of it in the market do not long remain unsold. C. W. S.

THE KITCHEN GARDEN.

EARLY RADISHES.

EVERYONE who possesses a garden, be it large or small, should endeavour to secure a few early Radishes. In the spring season a good Radish is most enjoyable, as it has then a better flavour and is more tender than during the hotter months of the year. In moist seasons Radishes are good the whole summer through, but in hot parching weather considerable difficulty is experienced in obtaining a free, quick, succulent growth. Those who are fond of this esculent should therefore lengthen the season during which it is in use by commencing its culture early in the year.

Early Radishes are best raised on hotbeds, but they may be grown both in cold frames and in the open ground. The earliest, will, of course, be grown on hotbeds, which should be prepared about the beginning of the year. Only a mild and gentle heat is needed, just sufficient to induce free germination, and promote a healthy growth. A strong forcing temperature will have the effect of developing leaves at the expense of the eatable portion. The seed should be sown upon 6 in. of ordinary light garden mould, covering it with some finely-sifted soil, and gently moistening it with warm water. As soon as the plants are above ground, ventilate as freely as the weather will permit, so as to secure stocky, sturdy growth. When the second leaf has been formed thin them out to about 3 in. apart which will allow room for their proper development. If sowings be made at intervals of a fortnight, during January and February, a good succession will be maintained until they are replaced by early outdoor crops. When sown in cold frames choose a sheltered but sunny situation, such as a well-drained border, and if the soil be not naturally very friable and rather light, some specially prepared mould should be put in the frame. By covering up at night and ventilating carefully, these sowings will come in considerably in advance of those made in the open air and will be found very acceptable.

To insure success in the open ground the soil should have received some previous preparation. It is of the utmost importance that it should be in a free, sweet, porous condition at the time of sowing the seed; no method more effectually secures these conditions than throwing the soil up into sharp ridges early in the winter, or, better still, during the autumn months. Wind and frost then penetrate it and thoroughly pulverise it, so that when levelled and put into order for sowing, it will be found to be in a good workable and friable state. The importance of this preparation of the soil for early crops is not, in a general way, fully realised, but it must be borne in mind that both germination and root-action are very sluggish at that time of the year. A dry, warm situation should be selected, sheltered, if possible, from east and north winds. Choose a day for preparing the seed-bed when the soil is in a fairly dry condition. Mark out a bed 4 ft. wide, the length being at the discretion of the grower. Turn the soil over with a steel fork, breaking all the lumps, and finishing off by raking it level. Sow the seed thicker than would be done later in the season, so as to allow for losses. The bed should then be covered with straw, or some Hazel rods may be bent over it and mats laid thereon. As soon as the plants appear above ground, the covering must be removed during the day and replaced at night. If strict attention be paid to this latter detail, a fair crop of early Radishes may be secured. Market gardeners grow a great many in this way, and they pay well for the extra labour has expended on them. J. CORNHILL.

VEGETABLE FORCING.

ALTHOUGH, except in the gardens of the most wealthy, the early forcing of fruits is not carried out to any great extent, every one who has the convenience of a few pits or frames essays to force some vegetables, and with a little judicious management it is astonishing how many profitable uses such structures may be turned to at this season, and what may be got out of them. If the pits happen to have a hot-water pipe along the front, no better place can be had for Asparagus and French Beans, the latter especially, as planted out there they are in almost as good a position as when growing on open borders outdoors in the summer. Confined to the limited area of a pot, with only a small portion of soil for their roots to feed on, they soon become exhausted and a prey to red spider; but planted out in a bed, with a little fermenting material under them to afford slight bottom heat, there is no end to their bearing. The best for early work is Osborn's Forcing, a most prolific kind, not over-robust, and one that is well adapted for frame or pot culture. If grown in the former way, the rows should be planted about 15 in. apart, and the Beans 6 in. from each other in the rows, which will afford ample room for the sun and air to play between, and thus insure a free setting of the blossoms. In preparing the hot bed, it is necessary that the manure and leaves be well mixed by turning them over a few times at intervals of two or three days, which will moderate the fermentation, and let out the gases that are so injurious to vegetation. This done, the mass will then be sweet and fit for use, and should be trodden regularly and firmly in the frame that there may be no further subsidence. The next thing is to place a few inches of leaf soil on the top, and then any light loam that may be at hand; and when this has got a little warm, all is ready for planting. To save time, where any one has the accommodation of a stove or warm house, it is a good plan to sow and raise the Beans in small pots or boxes, and plant them out afterwards; and if this be done in leaf mould, they lift with such patches or tufts of roots that they scarcely feel the removal, but start away freely in the fresh soil as if nothing had happened to check their onward progress. As soon as they are planted, the top temperature should be kept as near 65° as can be by night, and from 70° to 80° by day, according to the state of the weather, as there is nothing gained in forcing by a high degree of heat, unless there is light and sun in proportion, together with plenty of atmospheric moisture. This may be maintained by frequent syringings, which should always be done both morning and evening, whenever the weather is bright. A frame made up in the way described is not only good for Beans, but it is just the place for Asparagus, roots of which may now be dug up, and the heads ready for cutting within a fortnight or three weeks afterwards. The best plants for forcing are those that made plenty of top last summer, and which are strong and vigorous, with well-developed crowns. In digging these up, it is very important that as many of the roots be preserved as possible, as it is principally on the organisable matter stored up in these that the plants have to depend till fresh feeders are formed to assist in pushing up the several heads or shoots so much prized, and which are looked on as such a delicacy at this season. Instead, therefore, of using a spade, as is generally done in the operation of lifting, a steel fork should be made choice of, as with a tool of this kind the soil can be worked away in a regular and systematic manner, and the plants got out with little or no injury. As it is always desirable to make the most of the space under glass, the plants should be packed as close as they can be got together; and, in order to fill up the interstices between, the best way is to scatter a little soil, when, by keeping the lights closed and darkened, the seeds will soon germinate, and must then have air to keep them from becoming drawn. As forced Carrots are used as soon as they are about as large as Radishes, they may be left to grow without much thinning, and by taking the most forward at each pulling, room is then afforded for the others to come on.—"Field."

Tomatoes in Winter.—Like Mr. Gilbert (p. 45), I find Tomatoes to be a most useful addition to our supply of winter vegetables, and if such winters as the present were the rule instead of the exception we should have to devote more space under glass to similar subjects. I find Vick's Criterion most useful for pot culture. It is beautiful in shape and colour, and it sets and bears freely during the winter months.—J. GROOM.

Drumhead Savoy.—I find this to be most valuable this year for supplying a large amount of green vegetable food. In mild seasons, when Broccoli is procurable all the winter, Savoy, Kale, and similar hardy greens are at a discount, but now, when tender vegetables lie frost bitten and useless, hardy Savoy and Kale are appreciated. There is a general impression that Savoy and similar greens are not fit for table until after they have been frozen, which, if correct, may account for their excellence now; but probably their value is more enhanced by the scarcity of other vegetables than anything else.—J. G.

THE INDOOR GARDEN.

STOVE EUPHORBIAS.

BRIGHT-COLOURED flowers in winter are always in request, and they are all the more valuable when of a persistent character like our stove Euphorbias. Two of the most useful and best known are *E. splendens* and *E. jacquinæiflora*. The former is very easy to cultivate so as to have it in bloom in winter, when for bouquet making its flowers will be very valuable mounted on wire. To secure a free-blooming winter habit, the plants should be moved to the greenhouse by the end of June or beginning of July, and be fully exposed to all sunshine. If turned out-of-doors for a fortnight or three weeks in August, and placed in a warm, sunny corner, no harm will be done, as such treatment seldom fails to insure an abundant bloom when moved back to the stove. The long sprays of *E. jacquinæiflora* are well adapted for filling vases or other purposes of decoration; and, for the supply of armfuls of sprays for cutting, it should be planted out in a moderately warm house, in a light position. It may be treated as a wall plant, or be trained up a rope, or be planted in a thicket over an old hotbed, in a propagating house, or Melon or Cucumber pit; in short, it will do anywhere where it can have warmth and moisture to make its wood, and a drier atmosphere and plenty of light afterwards to ripen it. To grow it well in pots, the cuttings should be put in early in February, and be brought on in a warm house or pit near the glass. Starting them early permits of their being pinched back several times, thus securing a base that will produce a good number of flowering shoots. By varying the times of pinching, the plants can be had in bloom early or late, as required; and, after the first blooms have been cut, other smaller shoots will push out below that will flower later on in the season. The plants are easily propagated in spring. Young shoots, from 2 in. to 4 in. long, taken with a heel of old wood and inserted round the sides of large 3 in. or 4½ in. pots in sandy soil, and plunged in a brisk bottom heat, will quickly form roots, when they may be lifted out of the propagating bed, and as soon as hardened a little, be potted off and returned to the bed again, to be grown on to obtain large specimens. The pots of cuttings may be shifted on into larger pots without singling them out. Old plants do not flower so well as young ones; therefore few people care about saving plants beyond the second year, unless they are planted out and trained up a wall or under a glass roof, and then, of course, they assume quite another character. *E. splendens* is also easily propagated by taking off side shoots with a little heel of older wood attached. As they are very milky, the wounds should be allowed to dry a few hours before putting them in. One of the best plans I know for propagating this and similar plants is: after the exudation of the sap has stopped, and the wounds have become dry, thrust the ends of the cuttings into a warm, moist bed of sawdust, Cocoa-nut fibre, or tan, where the temperature is about 80° or so. March is about the best time for taking off the cuttings. Loam and peat will grow these plants well, with a sprinkling of sand added, unless the loam be of a sandy character. I may say all cuttings rooted as I have suggested, in sawdust, must be lifted carefully out and potted as soon as the roots are formed. If delayed too long, the roots may get torn off in taking the young plants out. In such a bed most plants will root in less time than if placed in pots. E. HOBDAY.

WINTERING PLANTS IN GLASS-FRONTED BUILDINGS.

THE description of a winter garden at Vienna (p. 12) reminds me of several structures of a similar character in which miscellaneous collections of plants used to be successfully wintered; indeed, in one particular instance I remember being much impressed with the fresh, healthy appearance of the plants. This was in the Botanical Gardens at Tübingen, where a long structure with a close roof and a high glass front like that of some of our old Orangeries was filled with a great variety of hard-wooded plants. They had, of course, been in the open air during the summer, but they evidently did not find their winter quarters disagree with them. In the Botanical Gardens

of Stuttgart, I saw a similar structure filled with the more hard-wooded kinds of stove plants, such as Palms and Pandanads, and I must confess that I was astonished to see them so green and healthy. The fact is, one is apt to be deceived with respect to the amount of light which the interior of such structures receive during the winter months. My own observations subsequently led me to the conclusion that the difference in the amount of light which would naturally exist between structures of this description and glass-roofed houses, was hardly in proportion to that experienced during the summer months. There is in the Villa Berg Gardens at Stuttgart a large Orangery, the front windows of which are some 10 ft. in height. The Orange trees were placed upon platforms at the back of the building, occupying about one-half of the area; the remaining space was filled with New Holland and other plants, and shelves attached to the windows with flowering Primulas. The plants all kept well, and the Primulas and similar plants were, to all appearance, as good as those kept under a glass roof. When there was a glimpse of sun in midwinter, I noticed that it illuminated the greater portion of the interior, rendering it quite bright and cheerful. But the most noticeable fact in the affair, and one which I repeatedly observed, was that whilst the morning and evening sun shone into the Orangery, the winter gardens which flanked it were quite deprived of its influence. All three structures had the same aspect, but the sun being low in the horizon its rays easily shone in at the upright windows of the Orangery, whilst they failed to penetrate the curvilinear roof of the glass houses. I then understood why plants should winter so well therein, and although I would, of course, prefer the convenience of a glass roof, I should have no hesitation in storing hard-wooded and any robust kinds of bedding plants in structures into which no light could be admitted through the roof, but the windows should be high, very light, and kept perfectly clean. The upper portion of the sashes should open the whole length of the building, so as to insure a free circulation of air without draught, and as there is no drip, and the windows are protected with wooden shutters, there will scarcely ever be need to make a fire. The almost entire absence of fire-heat, which, when applied, always exercises a more or less stimulating and, consequently, prejudicial effect on plants which should be kept quite cold, induces in bedding plants a complete state of rest, and, when turned out in the spring, they will be found to be very hardy.

I have been induced to make these remarks, believing that they may prove of interest to some who, being, perhaps, deficient in regard to glass space, may possess, and would willingly utilize, some such structure as I have described. In their interest, mainly, I have written, although there are few places, large or small, where storage is not a consideration, and even if there should be any hesitation in trusting soft-wooded plants in such places, there need not be the slightest fear of hard-wooded kinds being injured by a winter residence therein. J. CORNHILL.

HEATING AND VENTILATING IN COLD WEATHER.

MR. FISB has done well in calling attention (p. 30) to this subject for all the waste of force that takes place in gardens during winter that of the loss of heat is generally one of the greatest. It frequently occurs that as soon as those in charge of the fires see a little frost in the morning they rush to the stovehole and heap on fuel, be the sky ever so clear, and by so doing manage, by the time the sun is well up, to get the pipes so hot that the two together render the temperature so high as to be almost unbearable. Then air is given in abundance, chilling the plants and letting out the atmospheric moisture so essential to keep them in health. Now, giving air in the dead of winter, except during exceedingly mild weather and where houses are more than usually close glazed, is a mistake, as, in the generality of cases, there is more than sufficient passes in through the laps of the glass and other places, the tendency of heated air being to ascend continually and the cold to rush in to displace it. The very fact of having the interior of a house warmer than outdoors causes ventilation through the motion which it imparts, and as it is of a more regular and gradual kind than that obtained by letting down the lights, it is much better in every respect. If we can only draw in solar heat a certain amount of fuel is saved, and it is more congenial

to the plants than that obtained from pipes or by any other artificial means. With plenty of light, as there always is when the sun shines, it matters little about the thermometer running up 10° or 15° higher than usual, and by watching the weather and getting the sun to aid us we can always husband our forces and in that way save fuel. I always endeavour to impress on those in charge of the fires to keep them in abeyance till they see how the day is likely to turn out, when, if dull and cold, they are moved on slowly to reach the maximum of heat allowed by about 1 or 2 o'clock, after which they gradually fall away again for the night. If the sun be likely to break out they are stopped so as to keep the pipes as cool as possible till towards the afternoon, when they are started so as to meet the falling temperature and prevent it from going too low suddenly, thus making the best use of the light. Excess of artificial heat is one of the main causes of plants being infested with insects, and more particularly is this the case if attended by excessive dryness, a sure forerunner of thrips and red spider. Even if plenty of moisture can be kept up leaves become thin and flimsy, and especially is this so as regards Vines and Peaches forced early, while as to flowers obtained under such conditions, they are of the most fugitive character, and soon fade if cut from the plants. Not only is there a great waste of heat by having the fires going when they should not be, and the ventilators open to let it out, but much loss arises by letting the warmth that should be confined about the boiler escape up the chimney, instead of being expended in imparting heat to the water. If, instead of ashpit doors being wide open, and dampers out, the former were closed and the latter pushed nearly in, combustion would go on at a slow rate, thus making the fuel last double the time it does when a great rush of air passes through the furnace. This not only carries the heat with it in its course, but helps to cool the several parts as it travels on to the shaft, to which it speeds its way at a rate of which few have any conception. Of course a certain amount of draught is necessary to get the fuel alight and a clear fire going, but, once this is effected, the object should be to keep its strength and energy about the boiler, and there get as much out of it as possible. The damper and ashpit door give one full control, and if coke, breeze, or cinders be used with the coal in about equal proportions the flues do not become foul so quickly as they do when the latter alone is burned, the tendency of the dense smoke being to cause a tarry deposit to form, which, when it becomes thick and coated with soot, is almost impervious to heat.

S. D.

Early-forced Lilacs.—There are few plants that are forced into bloom much beyond their ordinary flowering season that are more generally appreciated than Lilacs. Although one of the easiest plants to force, there is considerable difference in the time which different varieties take to produce blooms fit for the flower basket, more especially very early in the season. I have placed plants of several varieties, for cutting from at Christmas and onwards, in heat, as soon as they had shed their leaves, and I found that the Persiau kind was in full bloom before such large-flowering kinds as Charles X. had scarcely begun to expand. Later in the season the difference was not so marked, but, as a rule, the kinds with small, slender, twiggy growths submit most readily to the quickening influence of heat, but after this season of the year large bushes of the common Lilac, taken up with good balls of earth and placed in the gentle heat of a Vinery or Peach house, answer perfectly. If required with white or blanché flowers light must be excluded from them, or else they must be forced very rapidly in a strong heat, which has the effect of producing the flowers so quickly that they contain no colouring matter.—J. GROOM, *Linton*.

Monstera deliciosa in Water.—This interesting Arad is never seen to thorough advantage, unless it is so placed that the roots have free access to fresh, pure water. There was formerly a very fine specimen in the Garden de la Muette at Paris. It was planted out near a water-tank in one of the plant structures, the stems turning round and covering an old tree stem, and the roots descending into the water below. It never had, I believe, any shade afforded it, pure air being left on the house during the summer, and an intermediate temperature only maintained in the winter. When I saw the plant, in August, it was completely studded with its cone-like fruit, and certainly presented a highly ornamental appearance. When grown in hot, moist stoves, this *Monstera* develops rapidly, and its singular foliage, together with the quaint forms which it often assumes, strike the uninitiated with wonder. High temperature and dense shade are, however, by no means necessary for its welfare; it enjoys a light, somewhat airy position, and when so placed it assumes a more shrubby, compact, short-jointed habit, and may be utilised for the decoration of apartments, corridors, &c. It should always find a place in sub-tropical arrangements, appearing, as it does, quite

happy in sheltered nooks, although most effective when placed near water margins.—J. C., *Byfleet*.

QUISQUALIS INDICA.

THIS sweet-scented stove climber, adverted to in a recent number of THE GARDEN, is far less cultivated than it deserves to be. It belongs to the Natural Order Combretaceæ, though very unlike the also far too little known *Combretum purpureum*. Both species, however, rank amongst the most beautiful of climbers. In colour it is a sort of orange-red, also a delicate pink, sometimes almost a white in the shade. This wide range of colour adds much to the beauty and usefulness of the flowers. By gathering them singly, and placing them in the dark in water, they lose most of their colour, but, fortunately, none of their inimitable sweetness. A downy-leaved variety,

Quisqualis indica.

called pubescens, was also introduced from Java about the same time; and two other *Quisqualis*, viz. *glabra* and *villosa*, are also occasionally met with in botanic gardens. *Quisqualis sinensis*, a rose-coloured species, was introduced from Canton in 1841; but it seems to have made but little way in cultivation, though it would probably do well in a conservatory. *Quisqualis indica* is, however, the favourite; and, being all that can be desired in a plant of this description—freegrowing, continuous-flowering, fragrant, and easily grown in a mixture of peat and loam—it is hardly worth while to collect other varieties. We have scarcely a plant more useful, or one more popular, or generally admired than a fine specimen of *Quisqualis indica* on the roof of a small stove; it is generally in flower from May to November.

D. T. FISH.

Sericographis Ghiesbreghtiana.—This is a very useful winter flowering plant, and although generally grown in a stove, in company with such plants as *Euphorbia jacquiniiflora*, *Thyracanthus rutilans*, *Justicia*, &c., it is nevertheless much hardier than most of them, and I have found it to succeed quite as well and to flower as freely in the temperature of an ordinary greenhouse. The flowers also remain in perfection much longer than is the case when the plants are kept in a plant-stove.—P. GRIEVE, *Culford*.

THE FRUIT GARDEN.

PRUNING ORCHARD TREES.

It is proverbial that doctors disagree, and doubtless many who read gardening papers come to a pretty correct conclusion that gardeners disagree quite as much, and on no subject more than on pruning. Probably nineteen out of twenty, if consulted, would say that certain trees needed pruning; and forthwith, armed with saw or pruning-hook, one half of the tree is cut away with results which, if satisfactory, are attributed to the pruning; if the reverse, to the season. Spring frosts always account satisfactorily for the absence of fruit, but many other minor reasons for its non-appearance exist, and some of these are doubtless attributable to haphazard pruning. The best trees as regards fruit bearing I have ever had are those that have been pruned the least. Standard fruit trees, if taken in time or looked over annually, only require central branches that cross each other to be cut away and the leading shoots shortened when young. In fact, in this neighbourhood, where Apples are grown extensively and bear enormous crops, the rule is to keep the centre open and let the outer young growth form as near as possible an umbrella-shaped head. Hard cutting of old or neglected trees is looked upon as worse than letting them alone, as old trees, like old people, do not recover from the effects of excessive amputation so readily as younger ones. Cutting off the annual growths of espalier, pyramid, or bush trees that have been continuously so treated is quite another matter, as if skilfully managed they are both ornamental and serviceable adjuncts to any garden. It is, however, to standards that we must look for our main crops, and I would strongly recommend any one having trees in an over-crowded state to cut out any dead wood, or small weakly growth that they may contain, but by no means to saw off large branches. Mulch the roots with good manure, see that birds do not destroy the blossom buds, and await the result. In this neighbourhood, where the ground is very much undulated, aspect has a more important bearing on the crop than in level districts. The orchards most noted here for constant bearing are those that slope to the south-west or west, as they do not catch the sun's rays until the blossom has become thawed and partially dry after the usually short sharp visitations of frost in spring. Much might be done in the way of shelter by planting a belt of evergreen trees on the eastern side of orchards to break the force of winds as well as to catch the destructive early rays of the sun. I may also remark that many of our very best Apples and Pears are wholly unsuited for orchard culture: therefore, if some of the pruning usually given to fruit trees were bestowed on the lengthy catalogues of varieties that puzzle and bewilder intending planters real good would be the result. In every county in which I have yet lived, some special kinds appeared suited to the district, and planters will as a rule find such kinds to fill their fruit rooms better than all the first class certificated sorts that have ever been sent out.

Linton, Maidstone.

J. GROOM.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Pine-apples.—I planted a pit 39 ft. long by 10 ft. wide, with seventy-five rootless suckers. From these the last fruit was cut eighteen months after they were planted, and the total weight of fruit from the seventy-five was 466½ lbs. I may also add that they were only subjected to fire heat ten months out of the eighteen.—M.

King of the Pippins Apple.—Mr. Baines (p. 52) is quite wrong in his ideas regarding the King of the Pippins Apple here. Many have seen and tasted our fruit of it, and all have pronounced it true to name and in every respect excellent. The flavour of Apples is often influenced by culture as much as that of Grapes or even Pine-apples. Young healthy trees, with plenty of nourishment at the root, always produce fine juicy fruit; and keeping the branches well trimmed imparts to it both high colour and flavour. I do not think more need be said to make this Apple more popular than it is, as, if Mr. Baines will refer to back volumes of THE GARDEN, which contain reports of the fruit crops from all parts of the kingdom, he will find King of the Pippins mentioned approvingly in most of them.—CAMBRIAN.

PLATE CIXI.

THE TEA-SCENTED ROSE.

Then will I raise aloft the milk-white Rose,
With whose sweet scent the air shall be perfumed.

Shakespeare.

THE newest happiness in the Rosarian's happy life has come to him in the Tea-scented Rose. When first, like Sappho, I was "enamoured of the Rose" (I wonder who sent it to her), we regarded *Rosa indica odorata* as the scholar regards an *Editio Princeps*, or the epicure a barrel of "best natives," or the gunner a woodcock, or the maiden of thirty summers a proposal—it was a rarity, a dainty, a phenomenon, which astonished us, like a kingfisher gleaming over a gloomy stream, and made us sigh "Oh!" and "Well, I never!" like the rocket of a thousand stars! It is true that at the time of which I speak, more than thirty years ago, we had in cultivation some of the most charming specimens of this fair family, such as Adam, Comte de Paris, *Devoniensis*, Madame Bravy, Niphetos, Safrano, Smith's Yellow (sometimes elegantly entitled "Jaune of Smith"), *Souvenir d'un Ami*, and *Vicomtesse des Cazes*; but we very rarely realised any of these out-of-doors (occasionally, in a favourable season Comte de Paris, *Devoniensis*, Safrano, and *Souvenir d'un Ami*); and Mr. Rivers, in his catalogue for 1847, after enumerating the varieties of "these fine and fragrant Roses," gives the prudent warning "they must not be trusted out in winter in exposed situations." Even in pots, and under glass, it was difficult to induce some of them to bloom, and "Jaune of Smith," I remember, had a chronic constipation, which no aperient could touch. Many a time, on the eve of a show, have I put him in hot water, and blown into him, as though he were on fire, and might just as well have attempted to open a box of sardines with a piece of buttered toast. The brave Rosarian, who, in accordance with Napoleon's idea of an Englishman, "never knows when he is beaten," persevered against all disappointments; he went on budding his Tea Roses in the summer, and the frosts went on killing them dead in the winter; he took them up and placed them by walls, and covered them with mats, and then transplanted them, looking but sickly, when the perils of starvation were past. He planted them, on their own roots, in sunny, sheltered spots; but the failures were infinite, and the fruitions few. There was a tiny plant of Adam, I remember, placed between two Peach trees on a southern wall, which produced a solitary flower, of marvellous beauty and of peonian size, and then gradually collapsed, and—whether from pride or from surprise, I know not—drooped, and died. There were a few glorious Roses, now and then, when springs were merciful and summers hot, on our standard trees of *Devoniensis*—such as my dear old friend, John Keynes, of Salisbury, once showed at Birmingham in his famous forty-eight (trebles)—there were, still more rarely, some precious pendulous blooms upon our *Souvenirs d'un Ami*, there was a greater abundance of Comte de Paris and Safrano; but many a season came and passed, and we, like naughty children, went to bed without our Teas.

The brave Rosarian lived on in hope—a hope to which some few things might be improbable, but nothing impossible ever. How could there be impossibilities to one who had witnessed the development of form and colour which had occurred to his experience among the Roses? who had witnessed with ecstasy the advent of *Géant des Batailles*, seen the Giant surpassed by the General (Jacqueminot), and the General almost extinguished by the glories of King Charles (Lefebvre)? What could be impossible to one who had seen the abominable little *Jaune of Smith* fly howling to the

wilderness (that is, the rubbish-heap) before the glowing splendours of our *Maréchal Niel*? No, thus encouraged, he would not despair,

Nor bate a jot
Of heart or hope; but still bear up and steer
Right onward.

Thus fortified, he could learn to labour and to wait, and though he waited long, longer than the lone watchman upon the palace-towers of Argos, when his royal master was besieging Troy, yet waited he not in vain—at last the beacon fires gleamed in the darkness, and "like volcanoes flared to heaven" the signals of a victory won.

When Mr. Prince, of Oxford, introduced the seedling Brier, he also introduced to Rosarians the power and happiness, hitherto unknown, of growing out-of-doors, in sure abundance, the Tea-scented Rose. The Italian stock, called Manetti, valuable as it is in many soils, and capable of producing in its "maiden blooms" all the hardier varieties of the Rose in the plenitude of their perfect charms, as Mr. Cranston, of Hereford, has demonstrated so often to our delighted eyes, was a miserable mother to "the Teas" (you might as well have asked one of the bronze lions in Trafalgar Square to act as wet nurse to a young kitten); budded on the standard Brier, or struck on their own roots, they were at the mercy of the first inclement spring; but now is the winter of our discontent made glorious summer by this seedling Brier, and in its custody our Teas are safe.

Here the question may be asked, Do you mean to tell us that, when budded upon this stock, the Tea-scented Rose will withstand a winter's frost? My answer is Yes and No; and I would add, in illustration of my meaning, the Irishman's words, "And shure I did say that they killed and murdered him, but I niver said they murdered him dead." A full explanation shall be given, by-and-bye, to my readers; meanwhile let us commence *ab initio*, let us build from the foundations, in order that we may be as well acquainted with our subject as the ornithologist, who remarked, in my hearing, to his friend at a poultry show, "I tell yer, Thomas, I've know'd that ere Dorking ever since he wor a hegg."

Collect your Hips from the hedgerows in autumn, place them in a flower-pot, and cover with sand to protect from mice, and keep them in a dry place through the winter. Sow in spring. Most probably the seed will remain in a dormant state and make no sign until the spring following, when it will come forth in such force that we have budded here some four hundred in a bed of this year's growth. The budded and unbudded are mixed together in a tangled mass, but the former are in excellent condition, notwithstanding the extraordinary frosts, and will be transplanted when the weather permits.

The buds, (and if the amateur inquires, where are they to be found? I advise him, when he is gathering the Hips, to order from the nurseryman a dozen or so of the best Tea Roses, already established upon the seedling Brier) should be inserted so close to the ground that they may be earthed over, and will ultimately make roots of their own. Whether transplanted, or left in the seed-beds, they must have a good circumference of clear space, say 2 ft. from the stem, for their growth. The first year they will be principally occupied in what we gardeners term making wood, though some may have a few good blooms; but in the next they will, in most cases, flower abundantly, this precaution being always taken (or the consequences will be fatal) to protect them, towards the end of November, with a thick covering of long straw-manure surrounding the stem, and partly screening the lower part of the plant. The upper growth must, of course, be left exposed, and this will suffer accordingly, but no amount of

frost to which we are liable in this country, will cause an entire destruction. In the last few weeks the thermometer in my Rose garden has been thrice nearly down to zero, but my Tea-scented Roses, though frost-bitten in the upper extremities, rest securely, like so many Sleeping Beauties, under their snowy counterpanes, whiter than swansdown, and their warm blankets of— of— a darker hue. And in the Spring-tide, "when the green leaves come again," they will wake to prove my affirmation that they have not been "murdered dead," and that we Rosarians have at last a successful method of growing the Tea Rose out-of-doors. I believe that in the last three summers I have cut, each year, more specimens of this exquisite and delicate variety than in the thirty years preceding, all united. From the altar of my church they have sent up their incense to Him "Whose breath perfumes them, and Whose pencil paints;" they have made my home bright and fragrant; and, to prove that they have been as admirable in quality as they have been abundant in quantity, they have won for me the first prize at the great show of the National Rose Society, held at Manchester in July last.

And now it may interest some of my brother and sister Rosarians if I speak of these Tea Roses individually, selecting those which I know to be most deserving of all the love and care which can be bestowed upon them. We begin, of course, and in spite of Darwin and his monkeys, with Adam, a very large and beautiful Rose, of a soft blush tint, somewhat capricious, like some other blushing belles, if the season is not quite propitious, but making us quite forget half-a-dozen frowns with one resistless smile. Without affirming the identity of this Rose with President as confidently as a French Rosarian, M. Guillot, fils, who begins his list of Rosiers This with "Adam (synonym) Président." I have the consensus of all the brotherhood in saying that the two Roses are very much alike (especially President), reminding me of a negro melody which I heard in boyhood, in which the singer, describing the marriage of our most gracious Queen, narrated how he

Stood close by Prince Albert, and the likenesses were such,
The Archbishop of Cantobury didn't know which was which.

Adrienne Christophle is a most striking Rose from its marvellous combination (I was about to write confusion, but Nature never confuses) of colours, yellow and red, the tints of the Apricot and the Peach, commingled. Aline Sisley is an interesting variety, its rosy-purple blushes contrasting remarkably with the paler complexions of the sisterhood, and there being only two other Tea-scented Roses (of which hereafter) having the same tone of colour. Anna Ollivier is one of those delightful Roses which always seem in good spirits, and anxious to do their best, healthy in growth, glossy in foliage, generous of its waxy, well-shaped flowers, in hue *rose carné*, a warm flesh colour. But what shall I say of Cathérine Mermet? I have read, in an old book of romance, of an excitable young knight who was so astonished and overpowered by the beauty of the young lady who had won his heart, that for some time, whenever he saw her, he made a point of fainting away. By a course of severe training, which he commenced by gazing on the castle in which the young lady lived at a respectful distance, which he gradually decreased, he ultimately empowered himself not only to admire her with his eyes, but to address her with his tongue; until, in an incautious moment, having made her an offer, he was so agonised by joyful ecstasies on receiving an affirmative answer, that he immediately fell down and died. I feel a certain amount of sympathy with this sensitive hero when I come into the presence of Cathérine Mermet, and am invited to describe her charms. I feel "that sort of drop-down deadness" which a certain bishop, according to Sydney Smith,

who was one of his canons, expected and admired in his clergy. I realise in some degree what it might be to "die of a Rose in aromatic pain." As for a verbal description, I am convinced that all the great poets, from Sappho to Tennyson, would have modestly declined it; and all the little poets, from the "poete minores Græci" to Martin Farquhar Tupper, would have made a frightful mull of it. No language is equal to such an undertaking, especially our own, which has been so worn and weakened by the constant use of its most expressive words upon trivial subjects, that there is no awe left in awful, and "oh! how lovely," means little more than nice. Wherefore I will leave our over-worked superlatives at rest and content myself with saying of Cathérine Mermet that both in form and feature, contour and complexion, "she's all my fancy painted her"—perfection. Passing by Cheshunt Hybrid, and postponing my praise until I speak separately of certain Tea-scented Roses, which seem to be more like the Noisette family in their vigorous growth, I am confronted by another exquisite specimen almost as overpowering in her loveliness as "the girl—I mean the Rose—I left behind me." In my hunting days I remember an uneducated *nouveau riche*, who was of a retiring disposition, when hounds really ran, thus endeavouring to account for his disappearance (as duffers always do) during a fast spin over a stiff country. "When I came up to that plantation," he said, "I could get neither to the right nor the left. On the one side there was a tremendous bullfinch, and when I rode to the other I came to a yawning dike; so that, in fact, I only went from Skilley (Scylla) to find myself at Carrybidee (Charybdis)." And such would be my perplexity, as I stagger in dazed amazement from the presence of Cathérine Mermet into the bewildering radiance of Comtesse de Nadailac, were it not for the welcome rescue of a true friend in need—I mean the artist whose admirable manipulations have presented to the readers of THE GARDEN so much of the beauty of the latter Rose. I say "so much," and I am sure that the artist will pardon the reservation, and will agree with me that although

Pictoribus atque poetis
Quidlibet audendi semper fuit æqua potestas,

it is not possible for dictionary or for paint-box to do full justice to this Rose. Very few painters could have done as much. The portrait is beautifully drawn, and the form is given accurately, yet with a graceful taste. There is too much of the golden hue in the petals, but the other tints are exquisitely realised. The English delineation is, in short, an excellent translation of the French description: *Fleur grante, pleine, rose carné luisant, a fond abricoté*, with just a *souffleur* too much of the *abricoté*. S. REYNOLDS HOLE.

(To be continued.)

ROSE CHARLES DARWIN.

CONCERNING this Hybrid Perpetual Rose, Mr. Geo. Paul states that it is a seedling of Mr. Laxton's, which some three years ago was placed in his hands for trial. It has proved to be a very fine Rose, with the merit of novelty of colour, having a brownish tint suffused over the crimson, and having a wonderfully decided habit of autumn flowering; indeed, throughout all the quarters, no single variety at this date (September 17) is covered to an equal extent with well-developed flowers. This is evidently due to some Bourbon blood in its parentage. On its merits, we have decided to distribute it next spring. Curiously enough, the English-raised Roses of the last two years seem to be the best of the new kinds. Taking those of 1876-77, Mr. Turner's *Excelsior* and Mrs. Baker (1876), with our Duke of Connaught and Sultan of Zanzibar, and Mr. W. Paul's *Magna Charta*, are the new kinds of the year worth growing. Of 1877, nearly the same holds good. Emily Laxton and Marchioness of Exeter, and Mrs. Laxton (1878), raised by Mr. Laxton, sent out by us; Mr. Postan's *May Quennell*, sent out by Messrs. William Paul & Son; and Mr. Davis's *Penelope Mayo*, sent out by Mr. Turner, are, with our own John Bright and Robert Maroon, the best of the year. Of the French kinds of 1877-78, taking first the Hybrid Perpetuals, we hold that Alfred K. Williams, a new Horace Vernet-like flower, Garcon's *Boldieu*, sent out by Mar-

gottin, a large, bold flower, and Edouard Dufour, of Lévêque, are the best amongst the crimson. Madame Jean Bowyer is in the way of Marie Finger, and is promising; Liabaud's two, Madame Gabriel Luizet and Madame Laboulaye, an improved Duchess of Edinburgh, are promising lights. Mr. Guillof's Hybrid Tea Mlle. Alexandre Bernaix, and Lévêque's Princess de Tremouille, are both free-blooming and La France-like Roses. Of the Teas, we think highly from flowers seen here, of Mr. Bennett's Madame Welch, a seedling of Madame Ducher, at Lyons; and Lacharme's Madame Lambard is a good vigorous free-flowering Tea, of soft rosy-peach colour, likely to be particularly useful. A new raiser, Nabouand, sent out some ten or twelve new Teas, some of which, as Princess Vera, look pretty; but to be useful now, a Tea Rose must have a bold vigorous habit and large perfect flowers, or we might as well revive some of the old varieties, like Caroline and Tea Jaune, which have been thrown out of the catalogues. It is pleasant to find that Roses continue to progress, and pleasanter to find English-raised kinds heading the lists.—"Florist."

NEW VARIEGATED TEA ROSE AMERICAN BANNER.

THE most striking novelty with which we have met in our long experience with plants, is represented in the accompanying engraving. For the first time, so far as we can ascertain, we have obtained a Tea Rose distinctly striped with crimson and white, and at the same time retaining all the valuable qualities of its class, viz., delicacy of colour and texture, exquisite fragrance, and continuous bloom. We have long had striped varieties of the hardy garden Roses, such as "York and Lancaster," etc., but these flower only once, and having but

New Variegated Tea Rose American Banner.

little merit are not generally grown. This new variety originated in 1877 with Mr. George Cartwright of Dedham, Mass., who states that it appeared as a "sport" upon the well known crimson Tea Rose, "Bon Silene." The leaf, from the axil of which the sporting shoot started, showed in one-half the leathery foliage of the "sport" while the other half had the foliage peculiar to "Bon Silene." We have frequently, in other plants, similar variations in the colour of flowers; for example, it is quite common to find one shoot of *Hibiscus Rosa-sinensis* bearing orange coloured, and another having crimson flowers but the foliage in such cases remains unchanged. Again, we have Carnations bearing at one time on the same plant, both plain scarlet flowers and those striped with scarlet and white. So with Dahlias, Verbenas, Petunias, and scores of other plants; but in all of these the flowers only vary, the foliage does not. In the case of this new striped Rose, the distinct change in foliage is to me more marvellous than even that in the flower. We have named this Rose "American Banner" as the colours are very nearly those of the stripes of our national flag. When a name can be to some extent descriptive it is always, we think, of advantage.—PETER HENDERSON, in "American Agriculturist."

the centre. The side beds are planted with Teas, consisting of the following kinds:—Lamarque, Devonienais, Safrano, Goubault, Niphetos, President, Maréchal Niel, and Gloire de Dijon. The plants are remarkably strong, and yearly produce immense crops of flowers. As a rule, Tea Roses receive little pruning, but here they are pruned in the same way as Hybrid Perpetuals, by which means they are kept within bounds, and larger crops of flowers are produced than would otherwise be obtained. The centre bed is filled with Cocoa-nut fibre, in which the pot Roses, brought on elsewhere are plunged, and from which the earliest blooms are obtained. A house like this can be put up at comparatively little expense, and, whether the blooms were required for cutting or not, it would always be a source of interest.—S.

THE FLOWER GARDEN.

PROPAGATION AND GROWTH OF LILIES.

I HAVE watched the controversy that has been going on between "Dunedin" and others respecting Lilies, and, as a propagator and at one time a grower of thousands of Lilies of various kinds, my experience teaches me that none of the writers in question have yet reached the root of the subject. Although I agree in the main with "Dunedin," yet I must say that some of his statements are unsatisfactory. I have no hesitation in asserting that Lily bulbs are reproduced in their entirety annually. Commencing with their propagation from scales, or parts of the old bulb, every scale, if removed with a sharp knife so as to have a small portion of the base adhering to it, will produce the first year a bulb about the size of a Pea on the side of the small portion of base left, and in some cases two or three bulbs. By allowing these to remain in the seed-pan, if not inserted too thickly at first, they form a larger bulb on the side of the small one. They are then shaken out and some five or six put in a 6-in. pot, when some of them would bloom, but I never allow them in their third season to do that. In the autumn they are fair-sized bulbs, when they may be planted singly, or, if of the lancifolium section, four or five may be put in an 8-in. or 9-in. pot; *L. auratum* takes a year longer to arrive at this size. Now, by attentively studying their growth during these four seasons many things may be learned; for instance, I never find Lilies perfectly at rest, and no sooner has the stem of the old bulb (which has, so far, supported the new one attached to its base) begun to show signs of decay and ceased its support, than the new bulb begins to throw out roots to support itself; therefore, I always repot as soon as ever the stem turns hard at the base and shows symptoms of ripening. Any one examining a bulb of *L. auratum* will find the base of the stem of the old bulb by the side of the new one, and easily detached from it, proving that like *Gladioli*, an entirely new bulb is formed, and, moreover, if the stem be rendered unhealthy by neglect the young bulb will be poor in consequence. I always judge bulbs by their size and healthy appearance, and I never knew a single instance in which a small bulb had a larger number or better blooms than a large one. If any bulbs produce weak stems I find that removing their flowers throws the whole energy of the plant into the stem, and, as a consequence, far finer bulbs are the result; this I discovered accidentally in 1865. Mr. Ray, the late curator of the Dean Cemetery in Edinburgh, had a very fine bulb of *L. auratum* which produced seven flowers—then thought something wonderful—and, according to the usual practice, he placed it, when done blooming, under a stage, and allowed it to stay there until next March, when he determined to repot it. On examining it he was surprised to find the pot full of new roots; he gave it a good shift, without disturbing it more than he could help, but May came before there were any signs of a stem, and when one was formed it was only half as strong as that produced the previous year, and the top was deformed. This ultimately got broken off, when the stem began to thicken enormously, so that by autumn it was more like the stump of a Hollyhook than a stalk of *Lilium auratum*; besides, it formed a number of young bulbils at its base and at the axils of the leaves, all indicating its great strength. It was allowed to remain undisturbed that winter, and next spring it threw up a magnificent shoot 5 ft. high, and produced thirty-five perfect blooms on that one stem. This, which was thought something extraordinary, was noticed in all the Edinburgh newspapers and visited by the late Mr. McNab and, I may safely say, by hundreds of others. It really was magnificent, and even now, when I have seen hundreds of fine examples of *L. auratum*, I never saw one which I admired more than I did that one, or one more perfectly formed. It did well without repotting for two more years, and then it broke into three stems, producing amongst them forty blooms. I left the neighbourhood, and know no more of its history, but it taught me to avoid late potting and to shift only when really

A Useful Rose House.—One of the best Rose houses which we have seen for a long time is that in the garden at The Poles, Ware. It is span-roofed, with a raised bed all round it, and one in

necessary. It taught me, moreover, that a year's rest from blooming gives strength and does no harm, and, finally, that bulbets on the stem show signs of vigour, and must be considered to be a natural method of increasing the plant.

EDINA.

STEM ROOTS OF LILIES.

It was fortunate indeed for "Dunedin" that he was able for the moment to shelter himself behind the remarks of "E. H. W.," but all that that writer says does not help him much. It is of little importance how many stem roots Lilies are said to have when growing naturally on the hills of Japan. What most concerns us is how they behave here under a thoroughly rational and successional course of treatment. We know that perfectly sound bulbs, grown on from year to year, that are never allowed to suffer from want of root room, loss of sap, or vital power, produce stem roots in abundance. In such cases they are most assuredly not "the result of error on the part of the cultivator." I once saw at South Kensington one of the first imported bulbs of *L. auratum* that had been simply potted on as it required more room. Speaking from memory, it had, I think, some eight or ten stems, was from 9 ft. to 11 ft. high, and had an aggregate of 147 flowers on it. I am pretty certain that no stem roots had ever been removed from that plant, though it had plenty, for the whole top soil was filled with them. Why, even when planted out, and where the soil and situation are most favourable, stem roots are produced in abundance; in fact, under every variety of circumstance, *Lilium auratum* can no more help producing stem roots than it can grow without food. The experienced cultivator notices every peculiarity and habit of his plants, and supplies their wants accordingly, and when he sees that such attentions lead to increased size and vigour, I repeat that it will require more than theory to convince him that his practice is wrong. The matter now stands thus: "Dunedin" states that the stem roots of Lilies—taking *L. auratum* as an example—are injurious, unnatural, and ought to be discouraged, in fact, amputated, and the only proof he brings to support his statement is to repeat "E. H. W.'s" assertion that this same Lily many thousands of miles away, behaves differently from what it does with us. Stem roots, in my opinion, are not injurious to Lilies; on the contrary they are perfectly natural, and ought to be cared for and encouraged. In proof of this let me point to the numerous successful instances of cultivation to be met with all over the country, where stem roots are always present and always encouraged, and where the annually increasing size and improved appearance of the plants prove to demonstration that these same stem roots must be beneficial.

Newry.

T. SMITH.

SCALES OF IMPORTED LILY BULBS.

"F. W. B." says (p. 560, Vol. XIV.), "'Dunedin' asserts that the scales of imported bulbs of *L. auratum* are dead when received in this country from Japan, and that the cell walls which make up the tissue or fabric of the bulb remain unaltered, and perform some offices long after life has departed. This, I am sure," he continues, "will be a surprising statement to many, more especially to those who have successfully used the scales of such old bulbs for propagating purposes. The fact is," he adds, "that the old scales of Lily bulbs which have flowered are not dead." I grant that those who believe in the perennial theory may be surprised. But those who believe in the successional bulb system, and who thoroughly understand the nature of the bulb and its scales, will not be surprised at what I have said. The fact is, the dead scales, in consequence of the persistent nature of the cell walls, are simply the husks, or external protectors of the embryo, and perform this office long after life has departed from them. If we cut open an imported bulb-scale, moisture may be perceived, but that is not nourishing matter. There is, however, nourishing matter deposited at the base of the scales, and in which the embryo is embedded. The cultivator, therefore, who desires to use these scales for propagating purposes, picks them off the core of the bulb, and plants them in a pan filled with soil properly prepared for the purpose. He then places them in a house, where they can have the benefit of heat and moisture, the result of which is, the embryos, nourished and strengthened at the expense of the stored-up matter around them (not of the scales), spring into life, and press through the integuments which cover them; the young roots protrude downwards and the stems rise upwards, throwing over the original scales, which—their office of protectors to the embryos being now accomplished—have nothing more left for them to do but to dwindle away and disappear. Mr. Baines (p. 561, Dec. 21) questions the correctness of my statement, when I said that the cells in Lily bulbs are so infinitesimally minute, that in a fresh, healthy, medium-sized *L. auratum* bulb, it has been calculated that there are

not less than 300 millions of them. At first sight this number may certainly appear to be somewhat apocryphal, but it is nevertheless correct. With regard to the value of large bulbs compared with smaller ones, Mr. Baines differs from me entirely, but in doing so I think he overlooks very important facts. In the first place, if we take a newly imported *L. auratum* bulb and cut it in two from the apex to the base, we shall have disclosed to our view, portions of three distinct bulbs; that is, part of the old dead bulb which bloomed last season—the new bulb which has been inclosed within the old bulb, and which was destined to bloom next season—and the seed-bud distinctly observable in good bulbs by the naked eye, and which was destined to grow up and bloom the season after the next. This representation of what may be called "three in one," is what is termed the successional bulb system, so entirely ignored by Mr. T. Smith, of Newry, but which has been proved over and over again, within the last two years, to be correct. Further—if we take half-a-dozen large bulbs and cut them open in the same manner, we should find that the new bulbs, within the old ones, varied very much in size. Had these bulbs been planted, some of them might have bloomed extra well; but others would have caused, very possibly, much disappointment to the buyer, notwithstanding that bulb importers persist in telling us, that what they offer for sale are all sound, flowering Lilies, and such as will produce a flower spike with from eight to ten blooms. Of this, as a fact, whatever they may venture to say, they can know absolutely nothing, nor can any one else. The cause of the difference in apparently similar bulbs it may be desirable to have explained. In order to do so, we must suppose that we have gone back to the previous season. During a period of five or six months previous to the appearance of the flower buds on the parent plants, the new bulbs within the old ones (not being very large at the beginning of this period), undergo, according to experimental facts, a complete transformation in regard to size. The nourishment, or elaborated sap, as it accumulates in the bulb, causes the scales of the new bulbs to enlarge in a lesser or greater degree, so that before the parent bulbs begin to bloom, the new bulbs may have enlarged, some very slightly, but others one-fourth, one-half, and sometimes nearly double what they were at the beginning of the five or six months. Therefore, in purchasing large bulbs, as patronised by Mr. Baines, they may possibly produce the smallest sizes; for no one can tell beforehand what the new bulbs may turn out to be. Again, suppose we plant fifty or 100 of these imported bulbs, three or four out of every five may come up the first season and bloom fairly well. But then we ask, what is the reason they do not all come up and bloom equally well? This is just the question which many so-called Lily growers cannot answer. The young stems that have not come up have been so far destroyed by the larvae of Japanese insects that, before they were planted here, all connection between them and the nourishment accumulated in the bulb has been cut off. Hence, those stems, though a few of them may have appeared above the ground, have decayed and died. As a proof of this, I may mention that I have dissected many imported bulbs, and have found colonies of little, voracious, thread-like worms, about $\frac{1}{2}$ in. in length, feeding on the base of the young stems; so that, subject to such attacks, it would be impossible that these tender stems could live and thrive. I have even watched their depredations, for I have put small, fresh pieces of the stems into wine-glasses, with seven or eight of these worms into each glass, and have found that they each consumed more in a day than was equal to the bulk of their own bodies. As regards the time when they took possession of the bulbs, there cannot be a doubt that the ten to fifteen days they were exposed to the atmosphere before packing for exportation. I have said that three or four out of every five may come up, but, as that does not account for so great a general loss, I may further state that I have also seen, in very many cases, that, instead of feeding on the base of the young stems, these worms have consumed the young seed-buds themselves. The result of this is simply the loss of the successional bulbs which were destined to bloom the season after the next, and, consequently, the entire loss of the plants; for nothing else, in my opinion, can account for the wholesale destruction, which is a common complaint, in consequence of the non-appearance of imported Lilies during the second season.

DUNEDIN.

[Here, we think, this discussion had better rest for the present.]

Hardiness of *Stobæa purpurea*.—Having sown the first seeds of this plant, sent by Mr. Macowan to Mr. Wilson Saunders, permit me to say a few words respecting its hardiness. The young plants when up were first potted off singly and afterwards some were planted in the open garden. The latter flowered in 1871, and withstood the following winter without the least injury. I have also had this

Stobaea in different exposed situations along with ordinary hardy herbaceous plants up to the present time, and it flowered each successive season without that "little extra attention" mentioned by Mr. Hemley. I have also grown it from English-ripened seeds, and likewise from divisions, and have proved it to be perfectly hardy. It is a good plant for mixed herbaceous borders. Thistle-like plants I am aware are not general favourites, but this I hold to be worthy of a place in any collection of hardy plants.—C. GREEN, *Pendle Court, Bletchingly.*

A SUBSTITUTE FOR NETTLES.

I HAVE lately seen several notes in THE GARDEN about Nettles. Whether they are indigenous or not they flourish so luxuriantly in the woods here, away from all cultivation that we have sometimes made walking sticks out of them. Nettles were certainly well known to the ancient Greeks and Romans. Pliny, who was well up in all the plant-lore of ancient Italy, and gives a long account of their medicinal qualities, says nothing of their introduction from Asia. He begins his description by saying: "What can be more odious than the Nettle," and as many will agree with him, I advise them to try to supersede Nettles in their grounds, as I am doing, by substituting for them *Polygonum Sieboldi*. I think this is the right name, as I have compared the different species which are named at Kew, but I first got it several years ago from Standish, of Ascot, under the name of *P. japonicum*. It is quite naturalised in my woods, rejoicing in the cool, damp, open soil in which Nettles generally grow. It does not spread fast in the middle of Nettles, though it quite holds its own, and gradually beats them. It grows 7 ft. or 8 ft. high, bearing in August and September elegant tufts of white flowers not unlike those of *Spirea japonica*. It dies to the root with the first hard frost. Those who wish to try it should buy or otherwise obtain a plant, divide it according to its joints or knees, which, as its name denotes, are many, and plant them in a spare spot of moist, strong soil. When it has once been established, they may clear it out every autumn and plant it in their Nettle beds, as I do, but they will find it so persistent that when they think they have made a clearance, it will come up again the next summer as strong as ever. There is one covert in Windsor Park, near the Obelisk, in which I have seen it naturalised. C. W. D.D.

Edge Hall, M.L.P.s.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Planting out Soft-wooded Heaths in Summer.—In Alsace and in some parts of Germany soft-wooded Heaths of the *hyemalis* and *gracilis* types are planted out in the open air during the summer months. Beds of fibrous peat are made up for them, and they apparently thrive much better thus treated than when they are kept in pots, as they can be watered more freely, a great advantage where the summer sun is so fierce as it is there. When grown in pots they are liable to die suddenly, much in the same way as some of our choice kinds of New Holland plants do. Healthy plants to-day are not unfrequently total wrecks to-morrow. When planted out they do not appear to suffer in this way to the same extent, a circumstance which may be attributed to the free drainage to which they are subjected and consequent absence of stagnant moisture round the collar. When taken up and potted in autumn they do not appear to sustain any check, but flower as well as those grown wholly in pots. There is no reason why they should not be so treated in this country, extra luxuriance being insured with a corresponding diminution of labour. Although this question of planting out mainly concerns the soft-wooded section, it is not certain that the hard-wooded kinds would not also be benefited thereby. One of the oldest and most successful Heath growers in this country informed me that he once planted out a selection of the choicest kinds, and they "grew like Willows." Plants intended for specimens would probably be benefited by being planted out for a season, thereby endowing them with extra vigor.—J. CORNELL, *Byfleet.*

Winter-blossoming Wall Plants.—The severe weather which we have had has brought the list of outdoor flowers down to a minimum, as even the common pink China Rose, that for many winters has been procurable in quantity on sheltered walls at Christmas has this year been entirely flowerless for these two months past. The only plants that maintain their usual character for flowering in mid-winter are *Chimonanthus fragrans* and *Jasminum nudiflorum* both on south walls; the latter, as persistently as the frost destroys one set of flowers expands a few more of its bright yellow blossoms, while the *Chimonanthus* appears to defy the weather, and is now well furnished with both expanded and expanding flowers, by no means

showy, but the dearth of outdoor blossoms makes them doubly welcome when even the hardy Aconite and Snowdrop are at a standstill, and will probably be much later this year than usual.—J. GROOM, *Linton, Maidstone.*

Anemone-leaved Geranium.—This shrubby species is undoubtedly one of the handsomest of the genus, and, though not quite hardy with us, it deserves attention because it is one of the most useful of cool house or window plants. It is stated, however, that it is hardy in Devonshire. The stem sometimes attains a height of 3 ft. or 4 ft., and the plant in other respects seems to approach the true *Pelargonium*. It is a native of the Canary Islands.—J. S.

Clematises for Low Walls.—That these are well adapted for growing on low walls as well as high ones is clearly proved by a long wall which we saw so planted lately in a garden in Hertfordshire. The plants in this case are not kept trim and close, but are allowed to scramble along the ground at the base of the wall. Where, however, neatness is studied, the way to secure it is to cut down the plants to the ground in spring, and mulch with manure. When they break into growth stop the shoots beyond the first joint, and perform the same operation again and again until the wall is covered with flowering wood.—H.

Cambridge Botanic Garden, Mass.—In the directors' report upon the condition and progress of this garden just published, we find that the following interesting plants have flowered in it for the first time during the year. With a few exceptions, they have not flowered in cultivation before:—*Acidantha bicolor*, Hochst.; *Antirrhinum speciosum*, Gray; *Aster Bigelovi*, Gray; *Aster Curtisi*, Torr. and Gray; *Aster saluginosus*, Richardson; *Berberis Fendleri*, Gray; *Eremurus robustus*, Regel; *Eucridium Brewerii*, Gray; *Fedia Nuttallii*, Torr. and Gray; *Gutierrezia Euthamiae*, Torr. and Gray; *Gymnolomia Porteri*, Gray; *Hesperaloe yuccifolia*, Engelm.; *Iris Hartwegii*, Baker; *Lobelia Feayana*, Gray; *Palmerella debilis*, Gray; *Pancratium*, n. sp. Florida; *Physaria Newberryi*, Gray; *Polymonium carneum*, Gray; *Senecio Elliottii*, Torr. and Gray; *Senecio Millefolium*, Torr. and Gray; *Spirea coccinea*, Nutt.; *Townsendia sericea*, Hook; *Xanthosoma sagittifolium*, Schott; and *Zygadenus Fremonti*, Torr.

Permanent Beds of Cannas.—For the last six years I have left my Cannas out in the beds all the year round, and I find the plan so advantageous that I should never think of going back to the old system of lifting the roots in autumn. The growth is much stronger and the flowers larger and more numerous; but our beds are well drained and the surface elevated above the natural level, and there is 3 ft. in depth of good soil. When the frost in autumn kills the foliage, the stems are cut down, and the beds are covered 1 ft. deep with dry litter, which remains on till the end of April or beginning of May, or till the weather is settled, and by that time the few young stems are pushing through the soil; but I find it necessary to replant occasionally, not because the soil is exhausted, as that could be met by rich top-dressings, but because the growth becomes dense and crowded after standing two or three years in one position. Perhaps if they were planted thinly at first, this necessity might not arise, but to insure a good mass the first season we plant thickly, and in after years, as they become too crowded, lift carefully, and replant. I have never found any inconvenience to arise from this; on the contrary, it gives an opportunity to stir up the beds, and, at the same time, increases the stock of plants. This work is always done immediately after the covering is removed in spring, just as the plants are bursting into growth, and they seem to experience little or no check from it at that season, but start off as vigorously as ever. Of course, the work must be carefully done and the roots not needlessly mutilated.—E. HOBDAV.

Hardiness of *Streptocarpus floribundus*.—This charming plant has proved itself to be so far hardy as to have been well frozen in a pan in a cold house and to have only lost its old leaves, whilst the crowns and young leaves remain safe. This is proof conclusive that it will do well in any cool house, perhaps frame, and will thrive well in sheltered spots on rockwork in the open air. I have, during the past season found it to seed freely. The pods have a peculiar appearance, being erect, long, spiral, and pointed, bearing no inconsiderable resemblance to a small pod of the once famous *Raphanus caudatus*. They are long in ripening, but eventually produce fertile seed. A batch of seedlings sown in the autumn has withstood the cold so far, although they are so minute as to be almost indistinguishable. A gentle warmth would have kept them growing, and in the summer these would have bloomed freely. No doubt when the spring advances these small plants will grow rapidly. It is interesting to know that this plant can be thus freely propagated from seed.—A. D.

GARDEN DESTROYERS.

THE SMALL ERMINE MOTH.

(YPONOMEUTA PADELLA.)

THE caterpillars of this beautiful little moth are unfortunately very destructive to the foliage of any trees or shrubs which they may attack, and, when a fruit tree is infested by them; the crop of fruit on it for that year is sure to be spoiled. Their favourite food is the leaves of the Bird Cherry (*Prunus Padas*), from which plant the name of the insect is derived. In the absence of this shrub, which is not very common, the moth selects Apple, Pear, Plum, or almost any fruit tree, Black Thorn, White Thorn, or *Euonymus*, on which to deposit her eggs. It is curious that in some places only one kind of tree is attacked; if the White Thorn suffers the Apples escape, and *vice versa*. Sometimes only one kind of

Yponomeuta padella.

Apple is attacked, the others remaining untouched, even though quite close to the infested trees. At times White Thorn hedges are entirely stripped of their leaves and covered with silky webs by these caterpillars. Apple trees frequently fare little better, and have the appearance, when badly attacked, of their leaves having been burnt. The young shoots and leaves, when examined, will be found to be surrounded by strong, brownish, silken webs; their growth is not only impeded by these webs, but the caterpillars within them devour the shoots and leaves. Various methods have been suggested and tried for the destruction of this pest. One of the best is to destroy, when possible, the moths before they have laid their eggs; this is more practicable than it often is with other insects, as they are easily seen on account of their conspicuous colouring, and as they generally all make their appearance at the same time. As soon as any are seen sheets

should be laid under the trees during the daytime and the branches shaken or beaten sharply, when the moths, which are very inactive during the day, will fall off and may be easily killed. The webs should be gathered and the caterpillars killed; care should be taken during the operation, as the caterpillars are very likely to fall to the ground when disturbed. If the webs are high up in the trees they may be collected by the help of a few thorny twigs tied to the end of a stick. Soap suds applied by a garden engine, with sufficient force to break the webs and reach the caterpillars, has also been recommended. As the *Chrysalides* are found in the webs, the insects may easily be destroyed when in that state. In France the damage caused by this insect to Apple trees is very great occasionally. Professor Westwood states that he has noticed the Apple trees planted near the road between Abbeville and Paris, for miles entirely defoliated by these caterpillars. The branches were covered with webs, and not the least portion of green was to be seen, the webs from the branches reaching down in festoons to the ground, which, beneath the trees, appeared carpeted with silk. The moths make their appearance in June or July, and deposit their eggs, twenty or thirty in number, in a mass near a blossom or leaf-bud; these they coat over with a gummy substance, which forms a kind of scale over them when it dries. The caterpillars are hatched in the autumn, but remain under the shelter of the scale during the winter. When the trees are coming into leaf they leave their winter quarters, but as they still require a certain amount of shelter from the weather, they eat their way into the leaves, and live for a short time between the cuticles, feeding on the tissues, until they are sufficiently strong to bear the changes of the weather; they then make their appearance on the surface of the leaves, sometimes much to the astonishment of gardeners, who have probably attributed to the east wind, or blight, the brown colour of the Apple leaves, and are much surprised some morning to find the trees covered with well-grown caterpillars, when not one was to be seen the previous day. Having left the interior of the leaves, they collect together and spin threads until they form a thick web round a young shoot, enclosing several leaves, within which they live, feeding on the upper part of the leaves until they are finished, when they move to another shoot and form a new web. The larger ones sometimes cover several small branches and shoots; in this way each family makes several webs, which, filled with half-eaten, withered leaves, make the trees look as if they had been singed. The caterpillars are generally fully grown about the middle of June. They then collect at one end of the web, and, arranging themselves close together, each encloses itself in a leathery cocoon of white silk, and assumes the chrysalis state, they usually finish their cocoons on the same day. It is a curious fact in connection with these insects that they are not only gregarious when in the caterpillar state, but also when they become chrysalides. In about fifteen or twenty days, the perfect insects appear. The moths measure nearly 1 in. across the expanded wings, which are long and narrow. The colour of the upper pair is very variable, but they are usually of a leaden white colour, with about thirty small black spots arranged in rather irregular longitudinal lines near the margins of the wings, which are deeply fringed with livid-coloured hairs. The ground colour of the wings is sometimes pure white, or white, with a leaden or yellowish cloud in the middle, or pale or deep lead colour with every intermediate shade; the number of the spots also varies. The lower wings are leaden coloured, with a paler fringe; head, antennæ, body and legs, white. The caterpillar measures about $\frac{1}{2}$ in. in length, and is of a greyish-white or dirty yellow colour, with a brownish head; the body is sprinkled with a number of small black spots, and has one larger spot on each side of every joint. They are furnished with eight pairs of legs, the first three, the sixth, seventh, eighth, ninth, and last joints each bearing a pair. The chrysalides are of a yellowish-brown colour. S. G. S.

The Well Walk at Hampstead.—Efforts are being made to preserve the fine Lime trees of the Well Walk, Hampstead, which it was intended to cut down to make way for building operations.

NOTES FROM KEW.

Orchids.—*Dendrobies* in flower, in addition to those previously mentioned, include the pretty *D. moniliforme*, which strikingly resembles the better known *D. nobile* in habit of growth, but is very distinct in blossom, being rather smaller, with narrow segments of a pale rose colour, tipped with a darker shade, and a pointed lip of a rich magenta colour. It is a native of China and Japan, therefore it is well adapted for cool house culture. It is known also in collections under the name *D. Linawianum*. *D. primalunum* is another fine East Indian kind, which produces a plentiful supply of blossoms on the naked stems; they have a large shallow lip of a light primrose colour, and pinkish outer segments, making the plant an admirable object for suspended baskets. A singular little kind is the Australian *D. semulum*, which is similar in flower to *D. tetragonum*, but smaller, with narrow, pointed, cream-coloured segments, and a tiny purple, blotched lip; the blossoms are borne in clusters on the end of short, truncated stems. It is, however, worthless for general culture. There are few more useful Orchids than the old *Cymbidium sinense*, as it is easy to manage and very free-flowering, and though not showy, exhales a delightful fragrance, resembling that of Violets. The flowers are borne on erect spikes about 2 ft. high, and are of a brownish colour, streaked with dark lines. A very singular little Orchid is *Restrepia antennifera*, which is found on the new Granadine Andes, growing on trees at an altitude varying from 6,000 ft. to 10,000 ft. It bears numerous oval, fleshy leaves on short stalks and slender flower stems, terminated by blossoms of curious shape, as the thread-like upper divisions are club-shaped, much resembling the antennæ of a butterfly, and of a bright violet-purple colour, the two lower united and boat-shaped, enclosing the small lip, the whole being copiously spotted with purple. This very interesting plant is well deserving a place in every collection. The most noteworthy of the *Odontoglossums* are *O. luteo-purpureum*, a very handsome kind from New Granada, with spikes 2 ft. to 3 ft. long, branched at the base, and bearing numerous flowers $\frac{1}{2}$ in. to 3 in. across, with a large, yellowish, fringed lip, surmounted by a golden crest, and the outer divisions alternately barred with chocolate and yellow. *O. gloriosum* is another free-growing and profuse-flowering kind; the spikes and flowers are smaller than those of the preceding, the colour of the latter being pale yellow, with brown or purplish spots. The old *O. biconiense* is represented by some fine examples producing many spikes of rosy-lipped flowers, which, with several plants of the lovely *O. Pescatorei*, have for a long time aided in enlivening the cool compartment. *Oncidium cheiroporum*, a native of the Volcano of Chiriqui, and a somewhat rare kind, deserves a passing notice on account of its singularly-shaped blossoms, which are of a dullish-yellow and a waxy texture; also *O. sphegiferum*, a Brazilian species with a prettily-spotted, fiddle-shaped lip and chocolate and yellow-banded sepals. *Stenorrhynchus speciosus* is a very showy and interesting terrestrial Orchid, an old introduction from Tropical America. It has rather large, deep green, oval leaves, and produces spikes about 1 ft. high, terminated by a dense raceme of deep flesh-coloured blossoms, each accompanied by a membranaceous pale flesh-coloured flower-leaf. It lasts a long time in good condition, and is a plant of sterling merit. The lovely *Masdevallia amabilis* is one of the best of the solitary flowered section of the genus. The variety at Kew bears flowers of a rich violet-purple, with faint dashes of a lighter hue, the whole flower changing later on to a light violet colour. Its native habitat is at high elevations in Peru and Columbia. *Saccolabium Harrisonianum* is finely in flower with its dense, pendulous racemes of pure white, waxy blossoms, and yields an agreeable aromatic perfume. A plant of such chaste beauty as this needs no pen to recommend its culture. One of the best cool-house Orchids is *Ada aurantiaca*, which, by the way, is named here *Mesospidium*, the flowers being of a deep orange colour a colour rarely seen amongst Orchids, and it is, moreover, a very free grower and flowers profusely. Near to it is the rose-coloured *Mesospidium sanguineum*, equally desirable and well suited for basket culture, as the loose racemes have a pendulous habit. *Epidendrum xanthinum*, with yellow flowers, *B. ibaguense* and elongatum with pink blossoms, are remarkable for the length of time they continue to bear a succession of bloom, which is produced in clusters at the apex of the slender leafy stems 4 ft. 6 in. long. Maule's variety of the old favourite *Cypripedium insignis* is decidedly superior to the type as the colour altogether is brighter and the erect sepal is half white with a few purple spots, of which the type is destitute. *C. venustum*, var. *spectabile*, shows another instance of variation in the colour of the blossoms, as the side sepals are of a rosy shade and the colouring of the rest of the flower more distinct.—W.

A Good Table Plant.—One of the best plants we have for single vase or table decoration is *Pandanus Veitchii*. It has fine arching foliage that is beautifully variegated; it makes a good plant

in a small pot, and submits to the rather rough usage to which decorative plants now-a-days are subjected better than most plants. —J. GROOM.

NOTES OF THE WEEK

Epiphyllums on Stumps of Tree Ferns.—An excellent idea is being carried out in Messrs. Veitch's nursery at Chelsea, viz., that of planting *Epiphyllums* on dead stumps of *Lomaria* and other miniature Tree Ferns. A cavity to hold soil may easily be hollowed out the top of the stem with a knife, and either rooted plants or cuttings of *Epiphyllums* grow readily on it, bushy-headed, finely-flowered standards being thus obtained in a short time. If desirable, the naked stems might be clothed with Club Mosses or the small-growing *Ficus minima*.

Double Chinese Primulas.—These make a good display in the Pine-apple Nursery just now. The flowers, which are of good form and embrace many shades of colour, last much longer than those of single varieties, and are more useful for cutting. There is also a good display of semi-double-flowered kinds with finely fringed edges which come true from seed.

Goldfussia isophylla.—Though not one of the most showy of plants, this is well worth growing on account of its flowering in winter. It is a plant of easy culture, and one which grows into shapely specimens without either tying or staking. It is grown well at the Poles, Ware, bushy plants in 6-in. or 8-in. pots being literally covered with pale blue flowers, which associate effectively with dwarf *Poinsettias*, *Primulas*, and similar plants. Under good culture plants of it continue to grow and flower abundantly for several months in succession. Cuttings of it strike readily, and may soon be grown into neat specimens. Old plants should be cut back after flowering.

Variegated Eranthis.—All variegated kinds of *Eranthis* have suffered severely during the past severe weather, especially the broad-leaved silver kind, which, in many cases, is injured beyond recovery. Of this some nurserymen have lost nearly their whole stock. This is a matter to be regretted, inasmuch as the demand for variegated *Eranthis* has been very great during the past few years on account of their suitability for windows, covering walls, and for growing in the form of bushes or standards in London gardens or by the seaside. As market plants, too, they are much prized and realise good prices.

Primulas at Chiswick.—A fine collection of Chinese *Primulas* may now be seen in flower at Chiswick. It consists of plants raised in spring from seed obtained from every available source, and the varied forms and colours of both foliage and flowers render them attractive and interesting. The old double white is unusually well grown, and at the present time a mass of blossom. It might, with advantage, be more largely grown in gardens than it is, for few plants continue in bloom longer, or yield a better supply of useful flowers for cutting in winter. Light sandy loam is the best soil in which to grow these *Primulas*; they should have a temperature of from 50° to 55°, plenty of air, and due attention to watering. A little weak manure water when the plants show flower is also beneficial.

Salix cœrulea.—This Willow is now densely covered with its silvery catkins, and very beautiful it is in that condition. In ordinary seasons the catkins show themselves usually a little earlier, but I was not prepared for so fine a display of them during this severe frost as may now be seen in my Willow grounds. One tree of this Willow, standing on the bank of a small stream, is eight years of age, and its size is as follows: Diameter or spread of semi-pendulous branches, 25 ft.; height, 22 ft.; girth of bole at 2 ft. high, 26 in. It will be seen, therefore, that it is not only a very beautiful, but a very rapid-growing tree, and it has the further merit of belonging to that class of Willow that contains the largest proportion of the medicine called salicine. It is this property of the Willow that makes it of value as an anti-fever tree.—W. SCALING, Basford, Notts.

Pomegranates on Walls.—Two very fine specimens of *Pomegranate* may be seen growing on the front of Mr. Hanbury's house, at The Poles, Ware. They are not closely pruned in and kept trim, as is generally the case with *Pomegranates*, a system which deprives them of the greater part of their flowering wood; on the contrary, only such straggling shoots as it is absolutely necessary to remove are interfered with. Thus treated they produce yearly abundance of flowers, basketsful of which are now and then out for indoor decoration. At the present time they are furnished with multitudes of young, wiry, well-ripened shoots, which will evidently produce a

blaze of bloom in the autumn. These trees have no protection afforded them whatever, and they suffer no injury even in the severest winters, a fact which clearly proves that on sunny walls, in the milder parts of England at least, the Pomegranate may be made to form one of the most effective of wall plants. In the south of England Pomegranates frequently bear large crops of fruit, but in less favourable situations they blossom too late for the fruit to set and come to maturity. In this country they are only valued for their wealth of brilliant blossoms, which are unsurpassed for effect or for use in floral decoration. On the walls of Falmouth Palace the Pomegranate grows and flowers abundantly, and it may also be seen on sunny walls at Kew. In some of the London parks during summer the Pomegranate grows in pots, and plunged here and there in the green turf, has, when laden with bright coral buds and flowers, a fine effect, and there is no reason why neat bushy plants of it in pots should not be grown for conservatory or room decoration, and, when associated with Ferns and similar plants, they would be much more satisfactory than many other plants grown for such purposes.

Sale of Messrs. Rolison's Plants.—These are being sold by Messrs. Protheroe & Morris. Last week's sale extended over five days, and comprised extensive collections of Orchids, stove and greenhouse plants, New Holland plants, Tree Ferns, &c. The plants were more remarkable for variety than for specially fine specimens, but the few there were realised good prices. Amongst the more interesting may be mentioned—*Dendrochilum filiforme*, 15 gs.; *Odontoglossum vexillarium*, 10 gs.; *Cologyne cristata*, 11½ gs.; *Aerides Schröderi*, £7; *A. affine superbum*, £7; and *Anthurium Scherzerianum*, £11. We understand that the collections are not yet exhausted, and that other sales are to follow, particulars of which will be found in our advertising columns.

Leeds Gardeners' Benefit Society.—The twelfth annual report of this Society has just reached us, and it is satisfactory to find that it is steadily improving, both as regards members and funds. The object which the Society has in view is to make provision for members when sick and unable to follow their employment. The rates of contributions are 3d. per week, and 1s. each at the death of a member, and 6d. each at the death of a member's wife. Benefits to members, 10s. per week during the first twenty-six weeks, and 5s. per week during the remainder of such illness. At the death of a member £10, and at the death of a member's wife £7 is paid. The charge of initiation ranges from 5s. to £2 10s. according to age. At the Society's meetings, which take place the first Tuesday in every month, matters relating to horticulture are discussed, and occasional essays read thereat, thereby diffusing much useful information.

Orchids at Chelsea.—Even during this unfavourable season the Orchid houses in Messrs. Veitch's nursery are gay with choice and showy flowers. Among them is especially noticeable the chocolate-flowered *Oncidium Forbesi*, which has been in bloom for several months; its branching spikes floating gracefully over plants of the showy *Odontoglossum leopoldinum* and *Lycaste Skinneri*, the latter flowering freely even in 4-in. pots. A fine specimen of *Angraecum sesquipedale* bears a dozen snow-white blossoms and buds, and the brilliant *Sophranitis grandiflora* makes a fine display on the upper portions of arch-shaped pieces of virgin cork suspended from the roof. Small plants of the charming *Lælia albidula*, are growing on pieces of wood, each bearing six or seven flower spikes furnished with from four to six wax-white, violet-tinted blossoms. To these may be added a fine variety of *Odontoglossum cirrhosum*, the showy *O. Halli*, and *Lælia anceps Dawsoni*, the flowers of which have pure white petals, violet-striped throat, and purple-tipped lip. Lady's-slippers are also very interesting on account of their great variety of form and colour.

Flora of Switzerland.—After the masterly works of Tschudi on "Animal Life in the Alps," and of Heer on the "History of Vegetation in Switzerland," another work likely to be of high value is announced—H. Christ on the plants of that country—"Das Pflanzenleben in der Schweiz." The interest of the work is all the greater that Switzerland contains on its narrow area nearly all the diversity of plants which grow in middle and northern Europe. Many years' research of the author in the field, his previous works on separate parts of the Alps, as well as his connection with the botanists of Europe, have enabled Dr. Christ to publish a work which may be expected to range with those above mentioned. It will appear in four fascicules, with many illustrations, and four maps of vegetable zones, one of which—the distribution of Grapes and of several plants of the Föhn and lake regions—will appear this month. The whole work will be finished about the spring of 1879, the first half fascicule having just appeared.—"Nature."

THE WEATHER AND THE BIRDS.

A WRITER in a provincial paper, alluding to the severe weather which has been experienced, says:—"Yet the extraordinary cold has not been without its compensating advantages. It has killed countless weeds, (?) the pest of the farmer, and has destroyed myriads of insects, which, after what are called open winters, commit such ravages on young and tender plants in spring. The frost has also a mellowing power on the soil, and especially upon that of clayey land," &c. As regards the last clause of this quotation, few will be, I think, inclined to differ from the opinion expressed by the writer, but I do not by any means feel so sure as to the destruction of countless numbers of weeds by the action of the frost. And, as regards the destruction of insects, I am inclined to think that they are so hardy as to be unlikely to be seriously injured by frost of even the greatest intensity, more particularly when in the ova or larvæ condition. I have even heard of tender-looking green caterpillars being frozen so hard that when dropped upon a dinner plate they sounded as if composed of glass, and yet when gradually thawed in a darkened chamber they became as lively as ever; so that the comparative immunity from injurious insects, which is sometimes experienced after severe winters, is not to be ascribed so much to the direct action of cold as to the enforced diligence on the part of insectivorous birds, which, during severe weather, when food is necessarily scarce, make every effort to obtain larvæ. Therefore, cultivators, if desirous to obtain the full benefit resulting from severe winters, should prevent, as far as possible, the indiscriminate slaughter of such birds, especially at a time when they are rendering the greatest possible service. On the approach of severe weather worms and grubs of all kinds instinctively make their way deeper into the soil, with, no doubt, the two-fold object of seeking protection from the cold, and from their natural enemies the birds. At the present time blackbirds, thrushes, and various other soft-billed birds, may be observed in thickets, under trees, hedgerows, and similar places, busily engaged in pulling about decaying leaves and other vegetable matter in their diligent search for grubs, snails, and insect of all kinds, few things, in fact, coming amiss to them, and it may well be supposed that by this wholesome destruction they are conferring upon cultivators benefits which will go far to compensate for much of the injury they are apt to inflict on fruit crops if left unprotected when approaching a ripe state. Some of our small birds, such as the blue titmouse, are sometimes blamed for picking the buds from fruit trees, &c., and of this I believe the blue titmouse to be perfectly innocent, although he may now be observed to be busily engaged upon the branches of fruit trees and gooseberry bushes, searching diligently for scale and other minute insects, on which account he is unfortunately suspected of aiding the bullfinch in his work of destruction. Three species of titmouse are to be seen in gardens and orchards, but the small blue variety is the most common, and an exceedingly industrious, sharp-eyed little fellow he is. I have known him in a very short time to clear a large Orange tree and other greenhouse plants from greenfly as effectively as could have been done by fumigation; but I believe no one has ever found the buds of fruit trees or Gooseberry bushes in his crop, and if he ever removes a bud it is only when such comes between him and his insect prey. On the other hand, it will be well, during the present weather, to keep a sharp out-look on plantations of Gooseberries and Currants, as well upon wall trees of all kinds, but more particularly to see that all is right with the Apricot, which, being generally in the most forward condition, is most likely to be attacked, and as the bullfinch does his work quietly, as well as quickly, one or two will, in the course of a few hours, destroy the prospects of a crop of fruit during the coming season. Unfortunately, as regards the bullfinch, the gun is the only effectual remedy, as no attempt to intimidate or deter him will succeed.

P. GRIEVE.

Culford, Bury St. Edmunds.

EFFECTS OF THE FROST IN NORTH DURHAM.

WHEN the thermometer falls 6° below zero, one naturally expects that nothing, except the most hardy plants, will pass through the ordeal scatheless. On December 7 we had the amount of frost just mentioned, but at that time we had a covering of snow on the ground of from 2 ft. to 2½ ft. in thickness. Even this, however, did not prevent the frost from mutilating many of our finest shrubs. In some places the common Ivy on houses is literally browned, looking as if it had been burned instead of frozen. The Irish Yews in our parish churchyard here present a similar appearance, and a few days ago I saw several Deadwax with the same lifeless look; indeed, they appeared to be worse, for, when shaken by the hand, the leaves fell off in showers. Growing amongst these Deadwax are numbers of *Cupressus Lawsoniana* which are not in the least affected, nor is the *Arbutus*. Of Portugal Laurels many fine specimens are apparently

killed. At Lumley Castle I noticed a line of Portugal and Common Laurels planted alternately, and in this instance the Portugals appear all right, while the common Laurels are masses of brown, dead foliage. Cotonæasters, particularly macrophylla, have suffered, while Pyracanthas have asserted their superior hardiness. While speaking of Lumley, I may mention that the great weight of snow which we have had has been very destructive to forest trees, breaking off quantities of limbs and branches. In woods here I noticed that the Beeches—of which there are some of the finest in the north of England—had suffered greatly from this cause; many branches 6 in. in diameter have been broken off. Numbers of trees and shrubs have been barked by rabbits during the frost; there is scarcely a Thorn hedge in the neighbourhood that does not show marks of their presence. Passing from forest trees and shrubs to the flower garden, I find that Roses have sustained considerable injury, particularly Teas in low-lying and damp situations. In a border of Roses pruned in the latter part of November not an inch of dead wood is to be found, a result which I attribute to the early pruning. Wallflowers, Stocks, &c., have been dreadfully mutilated. In the kitchen garden autumn-sown Lettuces, except where very strong and the situation favourable, are all killed; the same remark also applies to Cabbages, Winter Spinach, &c., and Curled Greens, a staple winter crop hereabouts, also presents a woeful aspect, being all cut down to near the ground, and the whole crop consequently lost. Broccoli has fared no better; Savoy only have successfully resisted the frost. A well-known market grower here has directed my attention to his Pear trees, the blossom of which he imagines is killed. The wood of last year's growth appears sound and good and in a healthy condition, but this remark does not hold good as regards the spurs or blossom buds, which, when cut across, have a blackened appearance at the core.

TYNEDALE.

The Weather in North Nottingham.—Another fall of snow occurred here on the 18th of December, and covered the ground to the depth of 3 in. On the morning of the 18th we had 14° of frost. On the 11th and 12th of January the frost was likewise very severe, but on the 13th a rapid thaw set in, with rain on the 14th, and the 15th was very mild and sunny. The frost again returned on the 16th, and still continues. The effects of this variation of temperature on the early Broccoli and other vegetables, where not protected, are now apparent by the odour which they are emitting. I am afraid that as soon as a general thaw sets in the greater part of these crops will soon get into a rotten state. It will, therefore, be requisite to attend to raising spring substitutes as early as possible by sowing Carrots, Lettuces, Radishes, in pits and frames, where these structures can be used.—WILLIAM TILLEY, *Wellbeck*.

So-called Macadamising.—If the late Mr. Macadam, of road-making eminence, could return to this mortal life, he would be shocked to find how great atrocities are committed in his name, and there can be little doubt that he would repudiate with indignation the term "macadamised" as applied to the roads subjected to the process known by this designation. Macadam's roads, as constructed and repaired under his own superintendence, and according to the system originated by himself, were formed entirely of angular pieces of stone of such a size as to pass freely through a ring 2½ in. in diameter, and which were not above 6 oz. in weight. Modern contractors, however, instead of adhering to this method, cover the roads with large, jagged stones, rendering them unfit for traffic, and, owing to the supineness of the vestries, are allowed to "macadamise" to their hearts' content in this fashion, without any reference to the safety, comfort, and convenience of the public. Some of the principal inhabitants of Paddington, indignant at the condition of the roads in that parish, sent a deputation to the vestry at the meeting of that body the other day, with a memorial complaining that Macadam's system is not being carried out by the contractor, or enforced by the officers of the vestry. On the contrary, granite is used of excessive size and weight, and, even if the stones used were of the proper size, the repairs, the memorialists assert, are done in an unscientific and, consequently, extravagant manner. For two months the rate-payers have been taking notice of the local repairs in the parish, and have taken stones from the roads and the heaps in the stone yard, samples of which the deputation produced before the vestry. These stones are of large size: "huge layers of granite cubes," many inches deep, are, it is complained, spread over the road that is under repair, and filled in with fine gravel and sand. The gravel, in course of time, works up into mud, which has to be carted away, leaving holes for water to lie in, and ridges for horses and foot passengers to trip over. There is also great danger to the springs and wheels of carriages and carts. The subject was referred by the vestry to the Highway Committee, and in, justice, at least, to the memory of Macadam, it is to be hoped that some better system will be adopted.—"Pall Mall Gazette."

GARDENING FOR THE WEEK.

Conservatory.

The temperature required now for some time, with a view to rendering the house enjoyable, as well as suitable for the plants usually brought on into flower in other structures, will be sufficient to facilitate the blooming of many others that do not require forcing, but which, to have them in flower through the winter, need a little more heat than that afforded by an ordinary greenhouse.

Epacris.—These are not nearly so much used at the present day for conservatory decoration as their merits entitle them to be. There are numbers of kinds naturally disposed to bloom in the winter, but they flower much freer and fuller if placed in a temperature such as conservatories are ordinarily kept to at this time. Amongst them are the erect-growing varieties of *E. hyacinthiflora*, *candidissima*, *carinata*, and *fulgens*. In the more bushy-habited kinds the white *Lady Penmore*, *Salmonia* (salmon colour), and *Sunset* (fiery red), with others of intermediate shades, will, if accommodated with the little extra warmth to be obtained here, open their flowers much freer than when kept cool, and continue blooming for many weeks. They are much more generally useful than winter-flowering Heaths, on account of their being more easily kept in health, giving greater diversity of colour, as well as brighter and more cheerful looking blossoms, and better adapted for cutting. With the erect-growing kinds especially it is necessary to considerably reduce the preceding season's growth; consequently, the whole of the shoots have to be shortened back, and they may, where cut flowers are wanted in quantity, be so treated whilst in bloom. The bushy growers will also bear the knife freely. For the same reason, there need be no hesitation in cutting their shoots when in flower.

Acacias armata and Drummondii.—Amongst the many species belonging to this extensive family of handsome plants the great majority are too large growers or, through other causes, not well adapted for cultivating in pots, but the above two are exceptionally useful in this way. If the plants have made their growth early in summer and are well ripened up, the temperature of the conservatory will bring them on into bloom quickly, and the flowers will last longer than if developed in more heat. Both these Acacias, when they have attained anything near the size required, will be benefitted by three-fourths of the current season's growth being reduced.

Daphne indica.—This is another plant which should find a place in every conservatory, as its presence alone, without the aid of any other sweet-scented flowers, is sufficient to keep up the most agreeable perfume. Both the white and the pink bloomed varieties deserve growing. They will also flower much freer with the little extra warmth they receive here. Their agreeable scent is frequently the cause of more of their flowers being cut than is consistent with the well-being of the plants, which, unlike those mentioned above, cannot bear much cutting, unless, in the case of individual specimens that are very strong, and in this matter the cultivator can always be guided by the condition of the plants; if not possessing more than moderate growth, two or three wood-buds only will be found immediately round the base of the flowers. If strong, a number will exist at the base of the leaves lower down, in which case there need be no hesitation in cutting the flowers at the extremity of the shoot, leaving two or three of these wood buds to go on for another year, whereas, if the bunch of bloom from the weakly plant be cut, with the necessary wood and leaves attached to it, many of the shoots so reduced will make no growth at all the ensuing summer. It would be found much better if such plants as these were grown in considerable numbers in every establishment where choice flowers are in demand, rather than cultivating quantities of plants very inferior in their general usefulness to them.

Oranges.—Where these are treated so as to keep them in a healthy, vigorous, thriving condition, furnished with plenty of good deep green-coloured foliage, although old-fashioned, they are amongst the most effective and useful subjects that can be introduced into a large conservatory, bearing fruit in different stages of development for a great portion of the year, and producing plentifully flowers alike acceptable for the odour they give to the structure they are in, and also for cutting. There is one drawback to their cultivation, with which those who have had to deal with them in most cases will have become unpleasantly acquainted, their liability to the attacks of some of the worst insects that prey upon cultivated plants, particularly brown and white scale. Where the latter exists on large specimens it is impossible to keep them in health without continual attention. Now whilst they are dormant an effort should be made to get these pests well under; they may be altogether eradicated

by repeated dipping or syringing with strong insecticide, but to accomplish this it will often be found necessary to sacrifice the flowers for a season, as the continued washing with a solution sufficiently strong to destroy these most difficult of all insects to kill, frequently has the effect of stopping the development of the bloom buds, but the loss of a season's flower will prove to be well compensated for by the improved after condition of the plants and the great saving in labour. In small conservatories a few medium-sized plants of the ordinary sorts of Orange will associate well with Camellias, and the small-growing Otaheite kind that fruits so freely when not more than 12 in. or 15 in. high will be found suitable for standing in vases on brackets, or other prominent positions in either large or small houses.

Correas.—Amongst smaller-flowering, hard-wooded plants that keep on blooming for a considerable time, and are well adapted for conservatory decoration, are several of the varieties of Correa, of which may be mentioned *C. cardinalis*, *C. Brilliant*, and *C. bicolor*. The blooms last long on the plants, and, hanging gracefully as they do from the small slender branches, will be very useful in combinations of cut flowers.

General Keeping.—Complete order as to the cleanliness of the pots, tubs, and boxes wherein plants are grown, as well as the floors, stages, &c., in all houses is quite as essential to render them attractive as it is to secure the healthy condition of the occupants, and at no time or place is there a greater need for this than in conservatories during winter. By continual attention to this matter much better results will follow at an absolutely less expenditure of labour than where a general overhauling is made from time to time, and in the intervals doing little in this direction.

Greenhouse.

Kalosanthes.—There are few more useful plants than these for general decorative purposes, and coming in, as they do, in the middle of summer, when comparatively few plants are in bloom, coupled with the fact that they can be either made to do duty in conservatories, halls, corridors, rooms, or any place where flowering plants are required, makes them doubly serviceable. They will grow in almost any description of soil—peat or loam—the principal essentials to their free blooming being that the summer growth is thoroughly ripened and that the plants are kept now in the lightest position available, with their heads close to the glass. From their free disposition to root they can be propagated at any time of the year. If cuttings are put in at once time will be gained, as, if subsequently fairly treated, good blooming plants may be had in eighteen months. Cuttings can be got from any established plants, selecting the strongest shoots that are not going to flower, which will be easily discernible, putting three or four together in small pots in sandy soil and placing them anywhere where the temperature is a little above that of an ordinary greenhouse, but not enclosed under a bell glass or propagating frame, which, in their case, is unnecessary. Moderate-sized plants in from 8 in. to 10 in. pots are the most serviceable. Those that are intended for flowering the ensuing summer should now have their shoots regulated with a few stakes and ties just sufficient to keep them in an erect position.

Boronia.—Than these in the shape of small and moderate-sized plants, there is nothing more elegant in habit, or more suitable for greenhouse and conservatory decoration; the length of time they will last in bloom—three or four months—is an advantage. *B. Drummondii* and *B. pinnata* will be now coming into flower, and will keep on blooming through the winter and spring. *B. elatior* and *B. megastigma*, comparatively new kinds, are both beautiful, and *B. serrulata*, later in its flowering, is most desirable on account of its perfume; a small plant in a 6-in. pot will agreeably scent a large house. If a few of these plants are grown for interspersing about the greenhouse or conservatory, their distinct drooping habit will do much to relieve the over-sameness of *Pelargoniums*, *Fuchsias*, and the like. If kept in a low temperature at this time they are rather subject to mildew, but if accommodated with 40° in the night and a rise of a few degrees in the daytime, they are not liable to suffer in this way.

Chorozemas.—For a like purpose in giving variety, these will be found of very easy growth, producing for a considerable time their brilliant flowers in profusion. If a few varieties, such as *C. cordatum*, *opulens*, *C. varium*, *Chandleri*, and *C. varium nanum*, are grown in moderate-sized pots, they will do good service through the spring months. Their healthy green foliage is little subject to the attacks of insects, except red spider. These plants will bear keeping cooler than the *Boronia*s; the small amount of tying they need should now be done.

Epiphyllums.—The presence of the stronger-growing and larger-flowering kinds of *Epiphyllums*, now so seldom seen in greenhouses, is much missed. The grotesque habit of the plants is worth taking into account, and the brilliance of their flowers has no equal. There is little trouble involved in their culture, and they will bear comparative neglect and still succeed, provided a few details are not lost sight of. Plants that have had their growth well matured during the summer, which is essential to their flowering, by exposure to all the sun possible, should now be kept at the warmest end of the greenhouse with very little water at the roots, only just enough to prevent them shrivelling too much, for if, whilst subject to a somewhat low temperature, the soil in which the small amount of roots they make exists is at all over moist, the fibres will rot, to which cause may be often attributed their not blooming freely. *E. Ackermannii*, *E. crinitum*, *atro-sanguineum*, *E. speciosissimum*, and *E. speciosum* superbum are much more deserving of cultivation than many of the weedy subjects that now find favour. Plants of *E. truncatum* intended for late flowering to come on with just warm greenhouse treatment must likewise not have too much water at the roots until the advancing season affords more warmth.

Statice.—The long-continued production and enduring nature of the flowers of these, combined with their colour and distinct character, make them more deserving of general cultivation than they receive. As it is, they are much more confined to those who grow plants for exhibition than for home decoration; whereas if they, and such as the before-mentioned plants, are allowed a place amongst the softer-wooded greenhouse subjects usually met with, a much more effective combination is produced than where they are absent. *Statice*s are strictly greenhouse plants, but, at this time of the year, they should be kept in a temperature of from 40° to 45° in the night, as, unlike many other hard-wooded plants, they are never absolutely at rest, growing slowly through the winter; their roots are also continuously active; consequently, even at this season, they require the soil to be kept a little more moist than for most plants. There is one point in their cultivation that requires attention: the old leaves, as the gradually decay, do not fall off as in the case of the generality of plants, but hang dead upon them, and, if not removed when in this state, they are apt to go mouldy, and sometimes destroy the shoots to which they are attached.

Pot Roses.

Tea Roses in pots grown out-of-doors in summer and treated with the intention of having them well furnished with buds in the autumn, and then placed in a greenhouse temperature to enable the full development of these outdoor formed buds without much fire-heat, which they will do up to the close of the year, will now need to be managed with a view to their doing service in a like manner next autumn, for, when required to produce flowers in this way there should be no attempt to force them on so as to make farther growth and bloom after they have borne the first crop; but they ought not, as is frequently done, to be turned out for some time yet into cold frames where the soil about their roots will be liable to get frozen, unless precautions are taken to prevent this, as such treatment would affect their now more or less active roots and interfere with the growth they are expected to make during the summer. They should be put in a house or pit where there is the means of excluding frost, and any pruning that may be necessary it is better to carry out at once, allowing them to remain here until the spring, by which time their young shoots will begin to move, and whatever potting is needed can be done, and when the season is past for any frost likely to injure them, they may be turned out-of-doors where they are to remain for the summer with their pots plunged in ashes. Where there is an attempt to supply Roses all the year round, plants thus treated fill an important place, their bloom coming in before that of those subjected to more heat, but if they are to increase in size and vigor as is desirable, they must even now, after flowering, be cared for in a manner different from the rough usage to which they are often submitted when their blooming is over.—T. BAINES.

Flower Garden.

The first frost which commenced early in December and continued to the 26th of that month, caused but little apparent injury, doubtless on account of the snow covering and comparatively calm state of the atmosphere, but the second frost, accompanied as it was with strong north-easterly winds, attacking vegetation full of moisture, after the rapid thaw, with which the first frost disappeared, has been most disastrous to what of late we have been wont to term hardy plants. *Eucalyptus globulus* is killed to the ground; *Phoradendron tenax* is much injured; *Antirrhinum* and *Dracopis* are, I fear, quite killed. Of evergreens the Japanese *Bonnyons*, *Laurestinus*, and common *Laurels* are the only shrubs that at present seem injured, and of these none are seriously hurt, but it is rather a puzzle to know how it happens, that whilst these so-called hardy plants have

suffered *Chamærops Fortunei*, *Camellias*, and *Skimmias* should have escaped, as they certainly have done here. Plants of doubtful hardiness should still have the needful protection applied. Mulchings of stable litter at the base of the plants or over the beds in which they grow is a sure preservative of them to the ground line. All Roses should have such a mulching. The frost has quite upheaved many small plants, especially hardy kinds that were split up in autumn for next summer's bedding arrangements. Sedums, Saxifrages, *Sempervivums*, Mints, Arabis, &c., will, now the frost has gone, require to be pressed firmly into the ground, and spring flowers of every description require the same attention. The tenderer kinds of bulbs will need covering in severe weather, which can readily be done with evergreen branches, or with mats supported on hooped sticks, the ends of the mats being pegged to the turf. Beds of Cannas will be sure to suffer this winter, especially if not well drained; it will, therefore, be well to divide any plants that have been wintered under cover, and place in gentle warmth. Seeds of them, too, sown now will make good plants for putting out at the end of May. Soak the seeds for a couple of days previous to the sowing, and germination will take place immediately. *Acacia lophantha*, one of the most graceful and effective of sub-tropical plants should also be sown now in order to have good plants for putting out in May. Another fortnight will be sufficiently early to sow *Solanums*, *Ricinus*, *Wigandias*, *Ferdinandias*, and other free growers, as they are apt to get pot-bond and stunted before planting time when sown too early. Pelargoniums that were not propagated in sufficient quantity in the autumn should now receive attention; three cuttings in a 3-in. pot make fine plants for turning out to the beds without division. They strike freely at this season on a dry, warm shelf in a Pine stove, Peach house, or Vinery, where there is a minimum temperature of 55°. As bedders the following are amongst the very best, viz., tricolor *Sophia*, *Damareque*, bronze or zoned *Rev. W. F. Radclyffe*, and white variegated *May Queen*. These three varieties, with the addition of the sweet-scented and variegated *Lady Plymouth*, are the cream of all the variegated bedding Pelargoniums; they are compact in growth and contrast well with such plants as *Coleus*, *Iresine*, and *Amarantus*. When the weather is open trench and dig all beds and borders that are vacant, and each bed should have manure proportionate to the requirements of the plants intended to grow in it. *Calceolarias*, *Verbenas*, *Violas*, and all sub-tropical plants can scarcely have too much. Pelargoniums flower best when the soil is poor, but the beds should be deeply trenched with the view of resisting drought. Well roll all walks immediately after a thaw, they will dry off hard and smooth, but if left till dry the roller makes little impression on them. Complete re-gravelling or re-surfacing and turning walks as the weather permits, in order that they may get consolidated before a drier period arrives. The same remark applies to lawns, which at this season can hardly be rolled too much.—W. W.

Auriculas.—These have been still further reduced in size by the second severe frost, and they are now more completely at rest than I have ever before seen them. It has been necessary to go over the plants again and carefully remove decaying leaves and other extraneous matter, and to press the mould where it has been much loosened round the plants. Prepare compost for surface-dressing, an operation which must be done as soon after February 1 as the state of the weather will permit. I generally reserve a portion of the compost that was prepared for Hyacinths, which contains about one-fourth of its bulk of rotten cow manure. To this I add about as much more cow manure, and then I find it to be a most excellent dressing. The surface soil must be removed down to the first roots; indeed, it is as well to remove as much of it as possible without injuring any roots; then add the compost, pressing it in firmly.

Carnations and Picotees.—The weather has been very trying for plants of these, possessing a delicate constitution, that were planted out-of-doors late in the autumn. I find that such plants will not even live out-of-doors near London unless the precaution be taken to place a glass protector over them; it is not the cold nor even severe frosts alone that cause the injury, but continued wet combined with frost. A good plan is to place bell-glasses over the plants, but they must be raised about 1 in. or more from the ground to permit a continued circulation of air. It is worthy of note that growers of these flowers for exhibition as far north as Newcastle-upon-Tyne succeed remarkably well with plants put out in beds in the autumn. They use, of course, a good free porous compost, the beds are well mulched with dry, rotten manure, and the plants are held in their places by a neat stick. Hardy Cloves and others in open borders must be looked over, and loose plants secured in their places; they will not succeed if the roots be not made sufficiently steady to withstand a gale.

Hollyhocks.—These cannot be propagated so freely as Dahlias; therefore it is desirable to begin early. When a Dahlia root is lifted

in autumn there are no signs of any growth from the base of the stems, but with Hollyhocks the case is different; many of these will have a tuft of growths round the base of the stem, and if the plants have been in a house from which frost has been excluded, some of these may now be taken off, and either be inserted in sandy soil as cuttings, or they may be grafted on to bits of healthy roots. In either case care is requisite in watering, as they are liable to damp off, especially in a damp hotbed; the best place for them is a close frame inside a forcing house, with bottom-heat supplied from hot-water pipes; each cutting or grafted root should be inserted singly in a small pot, and the pots should be plunged in moderately damp sand. Keep the frame close at first, and apply water sparingly, but not over the leaves.

Pansies.—Those in pots in frames have made no progress, but advantage must be taken of fine weather when it comes to push the plants into active growth, as the principal object of growing the plants in pots is to have an early bloom. See that no insect pests are allowed to remain upon the leaves; a reddish-coloured aphid, to the attacks of which they are liable, will quite spoil them if not immediately destroyed. Red spider can stand more cold than some imagine, and will make its appearance with the first mild sunny weather. Slugs will also eat out the incipient flower buds.

Primula cortusoides amœna and its varieties frequently suffer from neglect at this season; the crowns push early, but they will not become very strong if the roots are allowed to become too dry. See that they are kept fairly moist. Our plants are in cold frames at present, and the pots are plunged in Cocoa-nut fibre refuse.

Aquilegias, such as *A. corulea*, *A. alpina*, *A. chrysanthra*, *A. glandulosa*, *A. californica hybrida*, and *A. corulea hybrida*, are all grown in pots and cultivated in the same frame with a few species of *Primula*. The leaves of all of them are liable to the attacks of red spider, and they can be treated to keep this pest in check when grown together.

Tulips.—These are now appearing aboveground, and in cold, wet districts it is necessary to place some covering over the beds to throw off superfluous wet and to protect the plants from severe frost. Growers for exhibition in the midland counties have strong iron hoops bent over the beds, which are kept in position by connecting rods of iron. These are covered with mats or stout canvas only when the weather is severe. Any covering left over the plants in fine weather tends to weaken them. I have not yet found it necessary to protect our beds near London at this season. When the leaves are dry frost does not seem to injure them, but if water be collected by the leaves and a severe frost occurs danger is to be apprehended.—J. DOUGLAS.

Indoor Fruit Department.

Vines.—Early forcing is a difficult and slow operation this season, and such it must continue to be so long as cold weather lasts. Continuous hard firing is in the highest degree debilitating to the Vines; so, for the present, low night temperatures should be the rule, and forcing should be done by a slightly increased day heat. Such increase of warmth is imperatively necessary where the Vines are advancing towards the flowering stage; but, where the buds are as yet unexpanded, make no advance in temperature till a favourable change in the weather takes place. Outside borders should be well protected in order to prevent them from being chilled by snow or heavy rains, and, if fermenting material be used for increasing the temperature of the soil, great care will be required to prevent overheating. Early Vinery borders should all be inside where Grapes have to be ripe in April and May. All Grapes now on the Vines should now be cut and stored in a dry room, for, if not done soon, a recurrence of mild weather will at once put the sap in motion, and two evils will be the result, viz., the Vines will bleed by being pruned so late, and the Grapes will burst as soon as they are put into the bottles of water. When the pruning is done, thoroughly cleanse the houses and Vines by rubbing off any loose bark, and painting them with the usual composition, both as a preventive against and remedy for insect pests. The borders should then be renovated by clearing off all the surface soil, working it out from the roots with hand-forks and replacing it with the best loam that is to be had, with which should be mixed a liberal allowance of 3-in. bones and wood-ashes or charcoal, the whole being pressed firmly about the roots. For the present, guard against exciting the Vines into activity by keeping the house as cool as possible, a month's real rest being more beneficial than twice that amount of uncertain rest.

Peaches and Nectarines.—These are most impatient as regards artificial heat, and hard firing proves fatal to them, therefore be content with a slow advance till daylight is longer and sunshine probable, when a push can be made with greater certainty of attaining

success. In any flower should be artificially fertilised to insure a good set. An active boy, with a camel-hair pencil, will do thousands of blossoms in an hour. The atmosphere should now incline to the dry side, and a chink of air be constantly kept on, but guard against the slightest current of cold air, which soon shrivels up any blossoms with which it comes in contact. Houses now being started should have the borders examined as to moisture; if dry soak them well with tepid water. Outside borders should have sufficient protection to exclude frost, snow, and cold rains, but artificial warmth is neither necessary nor desirable. Let late houses have the necessary pruning and cleansing on the first opportunity, and induce effectual rest by keeping the temperature at the lowest point commensurate with the future well-being of the trees.

Figs.—Usually the earliest of these are produced by means of pot culture, and with liberal treatment both as to attention and feeding, good returns can be had by this mode of growing them. The embryo fruit of those that were introduced into warmth in November will now be slowly developing, and if the drainage be open water will be required most days, for, after this stage the plants are allowed to become dry, the worst results may be anticipated. If the plants be plunged in a bed of Oak leaves (the best heat-producing medium for them), care must be exercised that the heat does not become excessive; 70° should never be exceeded, and the moment the roots protrude out of the bottom of the pots dispense with bottom heat entirely. A moist atmospheric temperature, averaging 55° by night and 70° by day, is necessary for plants at this stage of growth. Where the trees are planted out in inside borders, which is the best plan, such borders should at once have the needful annual dressing. If confined within reasonable limits, and such is necessary for fruitfulness, it will be impossible to give them too rich a top dressing. Rich loam, well-decayed cow manure, and lime scraps, in about equal proportions, constitute the best materials for this purpose. Water with tepid water to consolidate the dressing about the roots, and the house may then be closed, but fire heat should not be applied for a fortnight longer. Winter pruning of Figs is rarely necessary if summer pinching has been regularly carried out, but to prevent crowding it may be desirable to cut out any straggling, spurs, or eyeless shoots when the trees are being overhauled for their winter dressing.

Strawberries.—Those in flower should have the pollen distributed daily, and air given freely whenever the air outside is free from frost. Keep the plants reasonably moist, and avoid splashing the flowers with water. As soon as the fruit is set, thin it out to six or at most eight fruits to each plant, after which manure water may be given twice a week. Successional batches of plants should be placed in warmth fortnightly in order to keep up a continuous succession of fruit till open air crops are ripe. As a rule, about three dozen plants put into warmth fortnightly will ensure a moderate succession of fruit. Shelves for plants that are to remain in the one position till their fruit is ripe, may have a coating of horse droppings or turf cut the width of the shelf, and laid Grass side downwards; into this the roots soon find their way, and much labour is saved, as water is not so frequently required as it otherwise would be. The plan has one drawback only, and that is, the drainage sometimes gets choked, a matter easily avoided.

Pines.—Under the present unpropitious state of the weather, the rearranging and potting of Pines are impossible, but advantage must be taken of the first mild weather to accomplish these operations, as it is important that fruit now showing should have a bottom heat of 85°, and this cannot be maintained until a renewal or addition of fresh leaves or tan, as the case may be, is made to the bed. Till such extra bottom heat can be applied, do not increase the atmospheric temperature, as both should be advanced simultaneously. As to watering, look over the plants every week, and when strong fires have to be kept going, twice a week may be requisite, especially in the case of plants near the pipes. Atmospheric humidity is a necessary element in Pine culture, but requires judgment in the application; it should never be applied to such an extent that the condensation drops like rain into the hearts of the plants. The state of the outside air should afford some guide in this matter. All should bear in mind that an atmosphere continually surcharged with vapour is just as injurious as a dry one, and this may lead to the adoption of measures to avoid either extreme.

Melons.—Do not be in a hurry to plant these out. At this early season there is little danger of their being pot-bound, and the plants will make better progress if kept on shelves near the glass for another week or two than planted out. The soil should be got in to admit of its getting warmed through thoroughly. Moderately stiff loam, without any admixture whatever, is best, and if fresh dug from the pasture all the better. It should be well pounded when put in the

bed, and the lighter the soil the harder should it be made. Make another sowing in the manner recommended in a previous calendar.—W. W.

Storing Ice.—Mr. Dennis's icehouse (p. 59) will be found to be an excellent one; but as many do not possess such a structure, I would suggest the following method of storing ice, which I have seen practised, and which will be found to be a very easy and simple plan. A foundation of faggots was laid so as to admit of the water passing readily away, and upon this was thrown the ice, which was pounded as small as possible. Faggots were then used to keep the stack together; they were supported by stakes driven into the ground, and between them and the ice straw and sawdust were placed to keep out the air. When the heap had attained the required height, a quantity of leaves, then a layer of straw and faggots, or boards, constituted a covering. The ice kept nearly as well and as long in this way, as that within a structure similar to the one recommended by Mr. Dennis.—J. S. T.

Garden Labels.—Everyone knows the necessity of having plants in gardens properly named, and in order to do this effectually it is equally necessary labels should be used on which the names can be legibly written; this can of course be done, as it usually is on wood, terra cotta, zinc, and the like, but then the writing soon becomes obliterated. We saw, however, the other day a label which seemed to be an improvement on existing kinds as regards durability. It was made of prepared green paper or parchment, neat in shape and appearance, and on which the writing could be distinctly seen, and which latter never becomes obliterated until the label is thoroughly worn out. These labels, which are made by Messrs. Tebb, are extensively used in the gardens at the Poles, near Ware, where they are highly spoken of for use in Orchid houses or other damp places, as well as out-of-doors. It is also stated that after having placed them under water for a day or two the writing was uninjured, and the label as firm and good as before.—S.

Market Gardening and Want of Market Accommodation.—"A Market Gardener" writes to us ("Pall Mall Gazette") as follows:—Your note on the dearth of vegetables is accurate enough, but the suggestion to farmers to take up market gardening requires consideration. In the first place, the high cultivation required in market gardening demands a very large increase of capital, which not every farmer has at his disposal. In the next place, one of the main causes of the high price of vegetables is the cost of their conveyance to markets, on the one hand, and the difficulty and cost of the conveyance of the requisite manure for cultivation on the other. All the land suitable for market gardening within a reasonable distance of London is already put to that purpose, and if more land were to be taken up it must be further off, and at an increased cost of carriage. But the one great difficulty is the absolute want of proper market accommodation for vegetables. Go to Covent Garden and the neighbourhood of the Borough Market, two of the chief depôts, when the market carts are rolling in from all quarters with their produce, and you will then be able to form some idea of the utter want of suitable accommodation. Every street anywhere near these markets is blocked with dense crowds of cabbage carts. The nuisance to persons passing through these districts is already very great, and it would be well nigh impossible at all largely to increase the present supply. There is no doubt that farmers and landlords just now are having an exceptionally hard time of it, and it is not easy to see when or how times are to mend. If, therefore, any possible means could be devised for giving agriculture a fresh impetus or new grooves to work in, it would be of the utmost importance. Market gardening, however, at the very best, could be but a very small help.

Ivy in Fern Cases.—It is a common occurrence to see in the houses of persons who do not give their minds to the matter, Fern cases without Ferns, or with a few deplorable bits that, we are assured, will be very fine some day, but which too evidently will become smaller, and soon disappear. That the planting and managing of Fern cases is a very simple matter need not now be insisted on. It is a fact that thousands of persons start Fern cases and aquariums, only to fail in some way or other, and it is more of a moral than a scientific question, as to why and how it all happens. I wish to point out to all who possess Fern cases, and can make nothing of them, that they make capital Ivy gardens, and Ivies will generally live in them without any management at all, provided they have light always, and water occasionally. As a matter of course, the smallest-leaved Ivies should be planted, and they should be nicely trained on wires. When a case filled with small-leaved Ivies is doing well, it is a charming object, and much to be preferred to one occupied by two or three dying Ferns.—"Gardeners' Magazine."

ANSWERS TO CORRESPONDENTS.

Early Melons.—"A. D." (p. 69) thinks that "J. W." must have been puzzled when he got seven Melons recommended and only asked for two, but if "A. D." had noticed "J. W.'s" question he would have seen that he asked for two Melons suitable for an early crop to grow in a span, roofed pit, and two sorts suitable for a frame as a second crop. The reason I recommended Victory of Bath and Paradise Gem for an early crop was because they both stand any amount of forcing, and Paradise Gem will be ready a week or ten days before Read's Scarlet Flesh, and equal in quality, while Read's Scarlet Flesh and Victory of Bath come in together under the same treatment, and ten days is a consideration to a gardener as regards early Melons. Victory of Bath does fairly well in a hot-bed frame, but it is not so hardy as Golden Queen.—JAMES SMITH, *Waterdale*.

Fruit Trees in an Orchard House.—In answer to "J. E. W." (p. 69) allow me to say that these should be plunged to within 2 in. of the rim of the pots. Plunging maintains a steadier root temperature, and the flower-pot should be placed at the bottom of the hole in which to set the pot, in order to prevent the roots from running into the soil; there should also be good drainage to allow the water to pass away rapidly, as stone fruit can scarcely have too much water when in full growth. Deer, sheep, or cow manure makes a very suitable fertiliser for trees in pots. It should be made in small quantities so that it may be used fresh, and as soon as the fruit is fairly set, supply it regularly in a weak state till the fruit begins to change colour, when clean water must take its place.—JAMES SMITH, *Waterdale*.

How Best to Combine Fruit and Flowers.—"A. B." (p. 69) may rest assured that she has ample glass accommodation to have a superabundance of flowers all the year round. It is a hopeless task to attempt to grow fruit and flowers successfully in the same house, and therefore the plan suggested of assigning particular plants to each kind of house should be abandoned, and the hothouses only used as auxiliaries to bring plants on for the conservatory. The first step should be to make the greenhouse suitable for holding plants by removing or covering up the tank so as to remedy the moist atmosphere complained of, and also to arrange the heating apparatus so as to command a temperature of from 42° to 45° during the winter instead of the extreme heat she seems to have. By setting aside a hot and cold pit for the use of the flower department, and using the other houses for bringing things on when that can be done without injury, an ample supply of flowers should be obtained, but, above all, it is essential to have a gardener who understands the business, otherwise the very best appliances will result in failure.—T. B.

Conservatory Climbers.—A correspondent asks (p. 69) for a Good plant to grow on a trellis on the back wall of a conservatory; let me recommend him to obtain a good strong healthy plant, 3 ft. or 4 ft. high, of *Luculia grassissima* at once. What could be more delicious than the fragrance of this charming winter-flowering plant adjoining the drawing-room? The old plant here has just passed its best, after pouring out its fragrance from over 600 heads of bloom, commencing about the end of October, several of the heads of bloom measuring 1 ft. in diameter. Could a artificial compound manure has put quite new vigour into the old plant; this plant compound just suits the *Luculia*, I never saw the heads so large as they have been this year. The temperature in which this plant grows varies from 40° to 45° without sun heat, and it needs little attention beyond spurting and tying to the trellis. The soil which we use is good sandy loam mixed with sand and leaf mould.—WILLIAM CULVERWELL, *Thorpe Perrow*.

Mistletoe on the Oak.—Mistletoe is reported to sometimes grow on the Oak in England. Can you kindly name a few of the places in which it occurs in this country?—J. H. [According to Dr. Bull, of Hereford, Mistletoe grows on the following Oaks:—1. On the Easton Oak, on Ridgway Hill, Easton Park, Herefordshire, known for many years; first described by Mr. Edwin Lees in the "Botanical Looker out" more than twenty years ago. The tree is nearly 100 years old, and has several Mistletoe bunches upon it. 2. The Oak at Tedstone, Delamere, Herefordshire, described in 1851 (Dr. Bull), in the Woolhope Club's "Transactions;" a middle-aged tree with a large bunch upon it. 3. The Oak at Haven, in the ancient forest of Deerfield, North Herefordshire; described and figured in the Woolhope Club's "Transactions" (Dr. Bull). 4. The Bredwardine Oak, on the estate of the Rev. Sir G. Cornwall, Bart., discovered in 1871; also described in the Woolhope "Transactions" (Dr. Bull), where a fine photograph is given of the tree. The parasite shoots out from it in fifteen different places. 5. The Brinsop Oak in the Old Town Field, Herefordshire, discovered in 1871 (Dr. Bull). 6. The Hop Meadow Oak, Hampton Bishop, Herefordshire; discovered by the Rev. H. D. Stillingfleet, Rector of the parish, in 1872. 7 and 8. Two Mistletoe Oaks on the Buckenhill property belonging to Mr. J. H. Barneye Lutley, near Bromyard; one discovered by the Rev. H. W. Welter, curate, in 1873, and the other the same year by Mr. Shirley Stephenson, son of the Rev. Nash Stephenson, vicar of Bromyard. 9. Oak at the Hendre, Llongatock, Lingoed, Monmouthshire, discovered in the winter of 1870; described and figured in the Woolhope "Transactions" for 1871 by Dr. Bull. 10. Oak at Lindridge, Worcestershire; discovered in 1870 by Mr. John Timbercock of Witley, and described by Mr. Edwin Lees in the "Badham Cornet Oak," Badbury, Dorsetshire, described in Woolhope "Transactions" for 1874 (Dr. Bull). 12. Frampton-on-Severn Oak, Gloucestershire, belonging to Mr. Clifford (*Ibid*). 13. Mistletoe Oak, near Knightwick

Church, Worcestershire; discovered in 1871 by Miss Eliza Walker, of Knightwick. 14. Oak at Burningsfield Farm, Dunsfold, Surrey, the property of Mr. W. L. Woods. (Woolhope "Transactions," 1864). 15. Hackwood Park Oak, near Basingstoke, Hampshire (*Ibid*); a very old tree. A specimen of the Mistletoe from this tree was sent by the first Lord Bolton to Sir Joseph Banks, who described it in the Philosophical Transactions. There are notices of several other Mistletoe Oaks, and the former localities recorded, but these are all the instances, it is believed, in which the Oaks are now known to be living with the Mistletoe growing upon them.]

Names of Plants.—"A. A. Thom."—Apparently *Hæmanthus natalensis*, not so common as *H. coccineus*, but not rare.

Questions.

Large-leaved Saxifragas.—In "W. D.'s" useful observations on carpeting bulb beds (p. 56), mention is made of the large-foliaged Saxifragas, such as *oppositifolia*. Will "W. D." kindly inform us what Saxifrage he had in view when he wrote *oppositifolia*? I am much interested in Saxifragas, and what I have known as *S. oppositifolia* is not large-foliaged. "W. D.'s" advice is too good to allow of mistakes which have a tendency to throw doubt on the whole if not corrected.—THOMAS WILLIAMS, *Ormskirk*.

Fuchsia serratifolia.—In Harrison's "Floricultural Cabinet" of August, 1845, there is given an illustration of this remarkable and beautiful Fuchsia. I have had it in the open air almost ever since then, but this winter I have lost it. It never flowered well in the open air, but grew freely enough, and was worth growing, if only for its rich green foliage. Is it in cultivation now?—WILLIAM JOHNSTON, *Ballykilbeg, Co. Down*.

Carpeting Bulb Beds.—I wish to thank your correspondent for his answer to my wants in your last week's number, and also to ask "W. D." (p. 55) who has sent a very valuable contribution on this subject, if he would kindly supplement his remarks by a few words on flowering carpet plants for autumn bulbs, both remaining in the ground undisturbed, unless for occasional improvement of the soil, &c. What I wish is to be able to place over a portion of my bulbs, plants beautiful in foliage during winter, and flowering in the autumn. I should also like to trespass so much further on his kindness, as to ask whether all these carpet plants, spring or autumn, might not, if desired, in special cases, be used to cover deciduous herbaceous plants, with a pleasant winter foliage?—J. S.

Filmy Ferns.—What soil do *Todea superba*, *Hymenophyllum flabellatum*, and the like require? What temperature do they need in winter and summer? Is 40° enough in winter?—E. JOHNSON.

Schoolmaster Potato.—Having seen an advertisement in THE GARDEN relative to the above Potato, and the number of tubers in the second year, the enormous quantity of 60 bushels, I should feel truly thankful if the person who accomplished this feat would let the "Schoolmaster" come among us and enlighten our darkness in regard to the matter. Living, as I do, in one of the best Potato districts in the kingdom, I must say that I am incredulous on the subject. However, if the above statement prove to be a fact, then by all means let the "Schoolmaster" go abroad. Let there be no more famine or complaining in our streets after this. Such a feat as the above forcibly reminds me of the miracle of the loaves and fishes.—D. T.

Royal Botanic Gardens, Edinburgh.—Mr. Sadler, the newly-appointed curator of these gardens, first went there in 1854. For some time he was engaged in the conservatories, and also in the propagating department and herbarium. During the summer months he assisted Professor Balfour, the Regius Keeper. In 1855, on Dr. George Lawson (now Professor in Dalhousie College) leaving, Dr. Balfour appointed him his assistant in all matters connected with the botanical classes at the Garden, as well as in his duties as Regius Keeper. In 1861 Mr. Sadler was appointed secretary to the Scottish Arboricultural Society; in 1867 Lecturer on Botany to the Royal High School; and since 1858 he has been the Acting Secretary of the Botanical Society of Edinburgh. In 1869 the Royal Caledonian Horticultural Society awarded him the Neill prize of £50 for his many services to practical botany.

Garden Appointments.—Mr. Thomas Snelling, who has for the last twelve or more years been gardener to B. B. Hunter Rodwell, Esq., Q.C., M.P., at Ampton Park, near Bury St. Edmunds, has been appointed successor to the late Mr. Dale, as manager of the Milton Horticultural Society. Mr. Snelling, who is in the prime of life, is an excellent gardener and plant grower, and has for many years been successful as an exhibitor at the shows of the Bury and West Suffolk Horticultural Society. Under his management it may confidently be expected that the Gardens in question will be unlikely to lose any of their attractions.

Ten Thousand Five Hundred Barrels are a good many Apples—yet this quantity left New York city for Europe on a recent Saturday. There is always a demand for our Apples abroad, even in years of plenty there. While we are glad that the Europeans get our fruit, we regret that but little of the profits of the shipment reaches the hands of our fruit-growers." So says our contemporary, the "American Agriculturist." The facts may be worth the attention of our own growers or landowners.

"This is an art
Which does mend Nature: change is rather: but
The Art itself is Nature."—*Shakespeare.*

HOW TO HAVE CAMELLIAS EARLY.

It will, I think, be readily admitted that Camellias are the most serviceable and beautiful of all greenhouse plants, but, although this is the case, their value to the generality of growers would be considerably increased could they only induce them to flower earlier. Many make the attempt to get them to do this by putting them in heat with a view to force them, and wonder why it is that their buds fall off instead of swelling and unfolding as they expected to see them. Knowing that plants of nearly all descriptions may be got in bloom out of their natural season by the use of artificial heat, those unacquainted with the culture of Camellias attribute their failure to every cause but the right one, and persevere in the same course year after year till they give up in despair. As many may now be about to try the experiment with a portion of their plants, a word of warning may be useful. The only way to get Camellias to flower early is to start them early into growth, and if this be persevered in for two or three seasons they acquire the habit of flowering in the autumn and winter instead of the spring. By treating some in this manner I always have plenty of blooms in October, and from that time onwards, and these from plants trained on the back walls of Vineries where little or nothing else would grow, owing to the dense shade and absence of light. Any one, therefore, having such places vacant, cannot possibly do better than to utilise them as we have done, and if the work be set about at once, in order that the plants may make their growth when the Vines are forced, there will be a good prospect of cutting plenty of flowers at this time next year. Camellias in pots are all very well for the embellishment of greenhouses and conservatories, but to afford a heavy crop of bloom, and plenty of length of young wood for cutting with it, they must be planted out, as then, with an almost unlimited root-run, their growth is exceedingly strong and vigorous, and the cutting to which they are subjected does them no harm, but is rather necessary and beneficial than otherwise. With us they make shoots from 1 ft. to 2 ft. long in a season, and oftentimes considerably more, and, as they have now nearly filled their allotted space, I never hesitate to cut them hard back, and take a good length of wood with the flowers.

Although Camellias will do fairly well in almost any soil, they succeed best in either good fresh friable loam or peat, or a mixture of the two, and in preparing the border one or the other of these should be made use of and put in to a depth of 2 ft. or so. Owing to the great quantity of water the plants require when growing, and also at the time when they are producing their blossoms, it is very important that they have free and efficient drainage, and the best way to provide this is to place 6 in. of soft red broken bricks at the bottom of the border, and on these a layer of rough turves, to insure the interstices being kept clear and open. Some of the healthiest and best Camellias which I ever saw were grown in pure loam, and if this be used, as it may be with the greatest safety, where peat is not easily and readily obtainable, it should be chopped up and put in in a coarse state so that the roots may be able to ramify and extend themselves quickly. Peat should likewise be used in the same condition, as the tendency of all soils that lie long is to lose their fibre and general porosity, and more particularly is this the case with such as lie in a large body together and are subjected to heavy and repeated waterings like that of a border in which Camellias are grown. There is one thing, however, to be avoided, and that is, leaving no hollow places or cavities when filling in whereby the water may effect its escape without permeating the whole mass, for, if this takes place, plants that appear to have a good deal of water given them get little or none, and frequently languish from want of moisture at a time when they are supposed to have been abundantly supplied.

In turning Camellias out of their pots for the purpose of planting them out, the crocks at the bottom of the ball should be picked carefully from among the roots, and as many of these should be liberated and spread about in the new soil as can be done without risk of breaking or injuring them. They should then be slightly covered with some of the finer portions of the loam or peat, after which the final filling up of the whole border may be proceeded with. A gentle treading will make all complete, except a good watering to be given through the coarse rose of a pot, in order to settle the soil about the balls of the plants, and give them a start. Any tying in of the branches or training that may be required to keep them flat to the wall can best be done by straining some galvanised wire horizontally at from 6 in. to 9 in. apart, running the same through studs driven into the joints of the bricks in order to keep them in their proper position. The moist atmosphere and frequent syringings necessary when forcing Vines just suit Camellias, and I know of no situation better adapted to their growth. They are plants of a shade-loving character, and this shade the Vine foliage affords exactly at the time when it is wanted, which is during the summer months, and at the present season, when more light becomes indispensable, the leaves are gradually falling and admitting it by degrees. No artificial arrangement could therefore answer the purpose in so satisfactory a manner, and as Camellias are in no way subject to insects, with the exception of brown scale, there need not be any feeling of reluctance about introducing them into Vineries on that account. I make it a practice to give them a good washing with the garden engine just before the buds begin to expand, as then the foliage, from being so bright and polished looking, is a great ornament to the flowers, which are thus set off to the best advantage.

It may be that many who have not the convenience of planting Camellias out and growing them on the back walls of their Vineries to get them into early bloom, may have the facilities for doing so elsewhere in pots, and the course I would recommend them to pursue in such cases is to look over the plants which they have in stock and pick out all such as are without flowers buds and introduce them into moist heat soon after Christmas so as to induce an early wood growth. Any forcing house at work will answer the purpose, as it matters little what the variation of temperature may be so long as atmospheric moisture is in proportion, Camellias being plants that endure great extremes without sustaining any harm. This is very remarkable considering how susceptible they are of change, and how quickly they shed their buds when any attempt is made to force them, as then warmth, for a week or two sends the buds off in showers, and should there by chance any remain on, the flowers when they expand are never anything like the size they should be. It should be borne in mind, that not only will artificial heat cause the buds to fall off, but that dryness at the root will produce similar results, and those therefore who have plants they wish to see in full beauty by-and-by, cannot be too watchful of their wants at the present time. The great mistake frequently made, is giving water often and in dribbles, instead of sufficient to thoroughly soak the whole of the ball, and then allowing them to stand till they are in a fit state to have it repeated. The point is to preserve the happy medium. As regards the repotting of Camellias, experienced cultivators differ much in opinion as to the proper time at which they should have a shift; some think that it should be done directly the flower buds are formed, while others are equally persuaded in their own minds that the right season to shift them is directly the blooms fade, and before the young growth commences. For my own part I am in favour of the latter, as during the spring root action is much more vigorous than at any other time; and not only this, but the plants will then better bear any slight check which they may receive than when they are more advanced. The assistance, too, that the fresh soil affords when given them early, must tell favourably on their growth, and consequently on the number of blossom buds which they are able to form over what they would have done had the potting been deferred till a later period. Camellias are fond of liquid manure, liberal supplies of which should be given them from this time till about May or June. I have always seen the best effect produced by administering

clarified soot water, a stimulant that is particularly suitable to most plants, and is as useful as anything that can be used.

S. D.

HELIOTROPES FOR WINTER FLOWERING.

To have Heliotrope flowers in winter there should be a night temperature of 55°, in order to secure a continuous growth, and if the plants occupy a light position, each young shoot will terminate in a truss of flowers, and a long succession will be thus obtained. But if they do not occupy a light position, so that a certain amount of vigour and ripeness may be imparted to the new growth, the shoots will be weak, soft, and consequently flowerless. A shelf near the glass at the end, or amid the heated air at the back of the house, not far from the wall, if the house be a lean-to one, will be a suitable position. During summer the plants must have undergone a suitable preparation. When the stock of Heliotropes is propagated for bedding in spring, a few dozen of the most vigorous plants should be selected, and grown on specially for winter flowering. They should not be allowed to starve in small pots, but should be shifted into larger pots before they receive any check, and, as soon as all danger from frost is over they should be plunged in a bed of coal ashes up to the rims of the pots in the open air. All shoots should be pinched back, to induce a bushy habit, and by so doing flowers will not be permitted to form. The bed should occupy an open situation, and the plants must stand far enough apart individually to permit of a free circulation of air, and so insure robust, short-jointed growth. Such plants when placed on a shelf in a warm intermediate or forcing house in winter, will produce a large number of flowers for cutting from October to February or March. Good little bushes may be had in 5 in. pots; but the strongest will require a size larger. Plunging the pots in summer will save watering, and prevent the hot sun acting so forcibly on the roots at the sides of the pots, from which cause plants that are standing far apart, with their pots unprotected, sometimes lose their leaves. All plants grown for winter flowering are better plunged in the open air in summer than placed on the north side of hedges or walls. It is a mistaken notion to suppose the tops will take any harm from bright sunshine if the roots be protected. This refers to many other plants besides Heliotropes. A few of the most vigorous may, if desired, be trained as standards, with stems 12 in. or so long. By attention to pinching good bushy plants may be had in one season. The dark purple-flowered varieties are the best for winter blooming, as the pale-coloured flowers become still paler in brisk heat, but the dark varieties still retain a delightful tint of purple. Heliotrope flowers may also be had in abundance in winter from old plants planted out, and trained against a wall in a warm, light house—indeed, that is the best plan to adopt, if the flowers are wanted in quantity. The plants should be pruned well back about the end of August, or a little earlier or later, according to the time the flowers are required. The syringe should be used freely, to induce a free and vigorous break; but when once the shoots have fairly broken into growth less syringing will be required, as this, as autumn approaches, only tends to promote weak growth. After a good break has been secured, the size and number of the trusses of flowers will be in proportion to the direct light that reaches the plants, accompanied, as it should be, by a corresponding amount of heat. These are the two prime factors in the production of Heliotrope flowers in winter, and should always bear some relation to each other in forcing.

E. HOBDAV.

FRUIT AND FLOWER CULTURE COMBINED.

In order to keep up a good supply of flowers all the year round, a cool stove or forcing house, in addition to the glass "A. B." mentions (p. 92), is indispensable, as without that it is impossible to bring on plants during the winter to render a greenhouse gay, or afford anything useful for cutting. With a good light house in two divisions, where different degrees of temperature can be maintained, much may be done, as in it Roses, Rhododendrons, Azaleas, Deutzias, Spiræas, Solomon's Seal, Lily of the Valley, and similar plants, may be forced in con-

stant succession, while, in the other end, Poinsettias, Euphorbias, Bouvardias, Eucharis, Gardenias, Begonias, such as *manicata*, *nitida*, *intermedia*, and numerous other winter-blooming stove plants, may be grown in pots, besides which part of the roof may be utilised for training, near the glass, in the sunniest and lightest part, *Bougainvillea speciosa*, that will yield any quantity of flowers for cutting. Room may likewise be found in the same way for *Stephanotis floribunda*, and, at the cooler end, *Bougainvillea glabra* to succeed its congener that comes in so early. *Allamandas*, too, succeed trained in the same way, the single blossoms of which look well placed in plates of green Moss, associated with *Gloxinias*, *Cactuses*, or any others of similar form and character. A large lean-to, with a high protecting wall, such as that of a building, to form the back, is the best form of house where economy is a consideration, as it requires less fuel to maintain a certain degree of heat than a span-roofed structure does, having such a breadth of glass exposed for the winds and weather to act on. A common mistake many make when erecting houses for such a purpose is in not putting piping enough in, which necessitates more fire being used than would otherwise be required, and therefore, although there may be an apparent saving at the commencement, it becomes much more expensive in the end by annually increasing the coal bill. A boiler worked at half power is much cheaper than one that has to be driven hard to do its work, and if the requisite temperature can be maintained without overheating the water the atmosphere is always far more congenial and healthier for plants. As "A. B." has her Peach trees trained to the back wall, the front of the houses would be far more serviceable with raised trellises, on which might be placed the whole of the bedding material or anything requiring to be kept cool and airy, such, for instance, as *Heaths* and *Epacris*, or other hard-wooded plants of that character, any of which would likewise do well in the house "A. B." mentions as having a tank in it, and which causes it to be too damp for *Pelargoniums*. Such an atmosphere would be just the thing for *Cinerarias*, shrubby *Calceolarias*, *Libonia floribunda*, *Coronillas*, *Cytissus*, and such like that like moisture in the air, and which only thrive really well when they can be so accommodated. The Vineries may with advantage be utilised for growing zonal and other *Pelargoniums*, forwarding *Fuchsias*, *Roses*, early *Rhododendrons*, and anything else not subject to thrips or red spider, as these are the only insects to fear that attack Vines, for black and green fly can be readily destroyed. A greenhouse to be full of flower at this dull season of the year should be kept regularly at from 50° to 55°, and in this temperature almost everything except tender stove plants will stand and flower profusely. It may be some help to "A. B." and others if I state what we now have in such a structure that looks fairly gay considering the bad weather. Most notable are the *Camellias*, which, owing to the regular warmth we have maintained for years past, have got into an early blooming habit, and now form an imposing background for the miscellaneous plants staged in front. These consist of forced *Callas*, *Rhododendrons*, *Azaleas*, *Salvias*, *Eupatoriums*, *Ageratum mexicanum*, *Perpetual Carnations*, *Cytissus*, *Coronilla glauca*, *Schizostylis*, *Cinerarias*, *Cyclamens*, *Primulas*, *Hebeclinium inthanum*, *Linum trigynum*, *Sericographis Ghiesbreghtiana*, *Schizanthus papilionaceus*, *Solanums* of the different berry-bearing kinds, *Chrysanthemum frutescens*, *Double Prunesses*, and *Lilacs*. Interspersed amongst these are several fine-foliaged plants, the principal of which are *Hedychiums*, *Palms*, *Grevillea robusta*, and *Coprosma Baueriana*, with *Dracæna australis* and the *New Zealand Flax*. So good and showy are the *Linums* and *Sericographis*, that I would strongly recommend them to be grown by all who have to keep a house gay during the winter, and if a temperature anywhere above 50° is maintained, they will be found to be just at home and to expand their gay blossoms in the greatest profusion. Other most useful winter-flowering plants are *Libonia floribunda* and *L. penrhosiensis*, the latter especially; it forms dense, neat little bushes, quite covered with bloom, that continues coming on for a long time in succession. For lasting from the present season up till May, *Hebeclinium inthanum* is most valuable, and, although considered a stove plant, it does remarkably well in a warm greenhouse. In appearance, except as regards

the foliage, which is large and stout, it resembles the well-known *Ageratum mexicanum*, but has larger heads of flowers of a better colour, and, as these are borne at the apex of every shoot, well-grown specimens of it are objects of great beauty. *Salvia splendens* and *Heeri*, too, are quite indispensable where a little bright colour is desired, and, by growing the two, either one or the other may be had in flower from November till quite late in the spring. S. D.

—“A. B.’s” question (p. 69) is an off-recurring one. By skillful management and much attention “A. B.,” with her several houses, might manage to keep up a supply of flowers including cool Orchids for the house and conservatory, “all the year round,” and at the same time secure crops of fruit; but with the means at her disposal, and perhaps a little more glass added, which she is willing to do, she would do much better to separate the fruit and flowers as much as possible, and let each have their own treatment. Of course she could use her fruit houses for plants, especially bedding material, at those seasons when the temperature suited them. She will find that by this plan she will have both finer flowers and better fruit and more of both. She would first have to consider the wants of her establishment in each case, and arrange her houses accordingly; perhaps she might find it advisable to sub-divide some of them to suit different subjects at different times, and give and take both ways, and, above all, she should not attempt more than she can accomplish with the means at command. Such an arrangement she will find the best in the end, and it will afford no excuse for failure. I could give instances in which this plan had been adopted after many years’ trial on the “compromising system,” and the result was a greatly increased supply of everything without adding more glass. It is difficult to advise in such cases without seeing the place and learning particulars; but in “A. B.’s” case the fruit houses seem to be rather out of proportion to the plant houses, considering the supply required, and she might probably find it wise to detach part of her Vineries for plant culture, instead of using all for both purposes. She will not be able to keep up a supply of flowers all the year round without two plant houses, or one divided into two—a warm and cool division—according to the subjects which she grows; and these she will find it needful to supplement with some of her hot and cold frames, which she says are numerous. In short, “A. B.’s” wants are successional structures, however small, in which she can forward supplies as she wants them, and this question she should be able to solve better than anybody else, if she has a clear idea as to what specialities she wants and when she wants them, together with a little knowledge of the treatment required by each. Of course she will be able to grow a great many little extras in all her houses besides special subjects. J. S. W.

MR. BAINES ON BOTTOM HEAT.

WHATEVER Mr. Baines says on the subject of plant culture deserves attention; therefore I hope no apology is necessary as regards noticing a rather remarkable and prominent article of his in a contemporary very recently, more especially as it has a direct bearing on much that Mr. Baines has written in *THE GARDEN* lately on this subject:—

“Vegetable life,” he says, “goes to rest through the reduction in the temperature, even in climates that know no winter in the sense that we experience it. During this time the heat of the earth in which the roots are placed becomes gradually reduced, and reaches its lowest point when the mean day and night temperature of the air is at the lowest, after which it must of necessity begin to rise with the sun’s returning power. The earth absorbs heat slowly, through the greater or less amount of stagnant air in its upper surface, its warming powers being still further retarded by the natural disinclination of heat to descend, consequently it does not regain the heat it has lost during the period of the lowering temperature of the air nearly so quickly as the air is warmed by the sun’s increasing force; therefore, the aboveground parts of plants—that is, their stems, branches, buds, and leaves—are placed under the growth-extending influence of heat continually in advance and excess of the roots until the turning period has arrived in the hot season, when the force of the sun begins to wane, after which the conditions are reversed, by the earth being warmer than the air, until the lowest point of the

air temperature is again reached. I would here recommend those who look upon bottom heat in the measure now usually applied as all but indispensable to the successful cultivation of plants from hot countries to consider this fact, and I think they cannot fail to see that applying it as is ordinarily done—at the commencement of the growing season, in a volume equal to, or often considerably above that in which the heads of the plants are placed—is diametrically opposed to the conditions under which they are found in a state of Nature, where the earth heat is in excess of that of the air only at the time that the season’s growth is being matured.”

The hypothesis here broached, it may be perceived, will adapt itself to a good deal that Mr. Baines has written lately on practical subjects; but, unfortunately, it is about as incorrect and misleading as anything can well be. Any superstructure which he may raise on such a foundation must necessarily tumble to pieces, and, what is more, the journal which now gives his opinions such prominence has, since the days of Lindley, been a consistent opponent of the same, as might, I think, be proved by numerous references. We are not without evidence on the subject treated by Mr. Baines, and I refer your readers to the tables, showing the comparative temperatures of the earth and air collected by Lindley in his “Theory and Practice of Horticulture,” and which are, I believe, the best, if not the only, tables existing on the subject extant, and they all prove the statements of Mr. Baines to be quite imaginary, so far as any deductions can be made with regard to the culture of plants. I need only quote the Chiswick tables of temperatures, since Mr. Baines speaks more particularly of climates like our own, because they tell the same tale as the other tables. The Chiswick records of the average temperatures of the earth and air, extending over a period of ten years, show that for seven months in the year the earth 2 ft. below the surface is warmer than the air, sometimes as much as 3° 34', and only during two months less than 1°. The months during which the air is warmer than the earth are April, May, June, July, and August, and the mean difference between the earth and air during these months is less than 1°. The greatest difference in any one month is 1° 21', and the least for the same period 0° 21'. This represents the “excess” dwelt on so emphatically by Mr. Baines, and the slender basis of fact for the statement that the earth “does not regain the heat it has lost nearly so quickly as the air is warmed by the sun’s increasing force,” and so far as his assertions relate to hot countries they have no basis at all. The difference is so inappreciably small that no cultivator would think of taking it into account for a moment in practice. Within the tropics—those “hot countries” to which Mr. Baines tells us his remarks have a special application—in both high and low situations, temperate and warm, the earth is warmer than the air by a good many degrees all the year round. It would almost appear from the evidence that as we go farther south, till the tropics are reached, the earth gets warmer and warmer till it remains permanently at a higher temperature than the air. The conclusion arrived at by Lindley from this, and much more evidence of a similar kind, is as follows, to give his own words: “hence it may be considered an axiom in horticulture that all plants require the soil, as well as the atmosphere in which they grow, to correspond with that of the countries of which they are natives. It has also been already shown that the mean temperature of the soil should be above that of the atmosphere.”

Wortley.

J. SIMPSON

A FEW GOOD CONSERVATORY PLANTS.

THOSE who have conservatories which they wish to keep furnished with handsome flowers and foliage at all seasons of the year should pay particular attention to the selection of the fine-foliaged plants which they employ, as, being of a more permanent character than flowering plants that are introduced according to the season, the effect produced greatly depends upon them. In speaking of a conservatory, I mean one in which an intermediate temperature is maintained, or, at least, sufficient artificial heat during winter to dispel damp and maintain a light, buoyant atmosphere—say from 45° to 55°—in which plants from widely different latitudes will winter safely together. When the building is large and lofty, permanent plants in beds attain finer proportions and make altogether better central plants than those in pots or tubs. *Araucaria excelsa*, where it has room to extend, forms a beautiful specimen; Tree Ferns, such as *Dicksonia antarctica*, with

very tall stems, also look well, associated with Oranges, Lemons, Camellias, and similar plants. For large specimens in pots or tubs the following plants will be found well suited, having always a good appearance and being easily grown, viz. the New Zealand Flax and its variegated variety, plants which only need the shelter of a glass roof in the coldest parts of England; *Aralia Sieboldi*, which stands ordinary winters without any protection; *Dracaena indivisa*, a graceful growing plant; *Latania borbonica*, *Chamærops humilis* and *Corypha australis*, all indispensable for cool house decoration; *Hedychium Gardnerianum* and *H. coronarium*, both evergreen fine-foliated plants; that flower in summer. To these may be added *Ficus elastica* and *Monstera deliciosa*, both effective plants where space can be afforded for their full development. Amongst variegated plants the *Yucca aloifolia variegata*, *Eurya latifolia variegata*, *Solanum hybridum argenteum*, *Aspidistra lurida variegata*, *Ligustrum ovalifolium variegatum*, *Bambusa Fortunei variegatum*, *Agapanthus umbellatus variegatus*, and *Coprosma Baueriana variegata*, are all excellent in their way, and the last makes a good trailing edging plant. These are all easily cultivated, and moveable plants may be added to them so as to produce variations to any extent. Foremost amongst flowering plants stands the Camellia, which, in addition to brilliant flowers, has foliage which at all seasons, when in a healthy state, is very attractive. Where convenience exists, Camellias should always be planted out in good, rich loam, and well supplied with soft rain water. Amongst other flowering plants, Heaths, Epacris, Acacias, Daphnes, Azaleas, Coronilla glauca, and Chorozemas, all flourish, with ordinary care, in pots. Amongst old-fashioned plants now seldom met with in conservatories I find *Sparmannia africana* to flower freely even in the middle of winter. Climbers should form an interesting feature in conservatories, and only evergreen species should be used if winter effects be sought for. Flowering plants of a soft-wooded character, brought forward elsewhere, should be added according to the season. J. GROOX.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Myrsiphyllum asparagoides.—I have had this plant here in an unheated greenhouse for two seasons, and it is now as healthy and fresh as could be desired. During the autumn and winter months I find it to be most useful; it is easily cultivated, and is unique as a winter window plant, even in a small state. In summer it requires rest.—CHAS. McDONALD, *Garden House, Stokesley.*

Hedychiums as Fine-foliated Plants.—Although Hedychiums are beautiful-flowering plants, they are equally serviceable as fine-foliated plants, and for the decoration of large conservatories they are invaluable, as, under liberal culture, their stems attain a considerable height. They are plants of easy culture, growing freely in any ordinarily good soil, and they will withstand a wide range of temperature. A conservatory or intermediate house suits them admirably, and in winter a good stock of such plants is very useful where indoor plant decoration is carried on, as they are even more effective than many of the costly occupants of stove houses, which cannot readily be moved about in a season like the present without considerable danger of injury from exposure.—J. GROOX.

Jasminum hirsutum.—This is one of the best of stove climbers at this season, producing, as it does, large clusters of pure white, sweet-scented flowers. Here it is planted out against the south end of a span-roofed stove, as, being somewhat rigid in growth, it is not so well adapted for rafters. The first flowers are borne at the extremities of the shoots, and afterwards from the lateral branches for a very long period; in fact, a large, vigorous plant of it is rarely destitute of flowers. The most suitable soil in which to grow it is about equal portions of peat and loam with sand enough to keep the whole porous.—A. HOSSACK, *Ragley, Alcester.*

Large Shifts Best for Kennedyya coccinea.—This pretty greenhouse climber, when well grown so as to thoroughly cover a good-sized trellis, is very attractive, and makes an effective contrast with other flowering plants with which it may be associated. In order to form a specimen quickly and to induce the formation of flowering wood it must be treated somewhat differently from the ordinary run of greenhouse plants. It should never be in want of an abundant supply of nourishment from the time when it starts into growth until it ripens its wood. If shifted on in the ordinary way it is apt to get pot-bound, and, when once that occurs, it never regains its normal vigour. A healthy, well-rooted plant, in a 4-in. pot, should be placed at once in a 10-in. pot, affording the trellis thereto at the time of shifting. The compost should consist of turfy loam and peat mixed freely with sand, and a sprinkling of pieces of porous brick will help very much to maintain the soil in an open condition.—J. C., *Dyffest.*

THE FLOWER GARDEN.

ASPHODELUS RAMOSUS IN THE WILD GARDEN.

This vigorous and somewhat coarse herbaceous plant is typical of the great number of plants, to provide a fitting place for the growth of which was one of the objects which the writer had in view while writing the "Wild Garden." There is a host of vigorous herbaceous plants, which, while attractive during their short season of bloom, are so very much in the way during the rest of the year that few people think them worthy of room in their borders. Moreover, such plants are frequently, from their habit, far from being agreeable objects stiffly tied up in borders, while, allowed to form groups in copses, or woods, or rough shrubberies, they are delightful. Among those who have taken up the notion of the wild garden with much spirit, and illustrated it with great intelligence, is Mr. George Berry, forester at Longleat. He has already secured near many of the drives through the noble woods and outergrounds of Longleat some of the most charming effects we have ever seen in gardens, and in the face of the usual and relentless enemy of the wild garden—rabbits—which destroy so many of the best plants for it. The annexed is an illustration of one of the plants which he has established, sketched in the wild garden at Longleat by Mr. Alfred Parsons, and engraved by Mr. Hyde. The work of a forester in such a place as Longleat is no light task, and involves much attention to new and rare species of trees and shrubs and their propagation. To take up, in addition, the extensive flora of the wild garden, and make, in a very short time, such a judicious use of it, is deserving of grateful record on my part. The woodland drives of England, treated in the same intelligent way, would form lovelier gardens than were ever imagined, and in their presence the crude floral geometry of the present day would not get more attention than it deserves. W. R.

CARPETING BULB BEDS:

For the earlier blooming bulbs, such as Scillas, Snowdrops, Crocuses, &c., the Mossy Sedums make excellent carpet plants, as not only are they complete coverers of the soil, but, being shallow rooters and exceedingly dwarf, they permit the flowers of these bulbs to be seen in full beauty above them. The prettiest arrangement in this way that I have yet seen as a permanent border where nothing else would grow, was a carpeting of *Sedum Lydium* and Snowdrops. The varieties of the Mossy Saxifrages have growth of such similar character, that any of them would do for *Talips*, *Gladioli*, and *Lilies*, but these are undoubtedly grosser feeders than the Sedums and would, no doubt, soon impoverish the soil. The chief portion of the Saxifrages have white blooms, but a few have red and pink flowers. If these be desired as a contrast to the colours of the bulb flowers, it would be necessary to select plants that would flower simultaneously, and this might be a matter of difficulty as *Talips* are early and *Gladioli* and *Lilies* late. The Golden-leaved Chickweed, the Veronica repens, the dwarf Pennyroyal, and others of similar growth, all make good carpet plants of a permanent character, needing now and then a little trimming and attention. The early spring bulbs do so well in many old gardens upon Grass that it may be doubted whether there can be found any better or more enduring carpet plants than the Grassy covering of our lawns. Beds of bulbs might be planted here and there and be protected from the scythe and machine by wire guards until after they had bloomed and the foliage had died off; then the guards might be removed and the bed mown and thrown into the lawn. Crocuses and Snowdrops thus treated have thriven and done well for generations. It is questionable whether the best *Gladioli* would do as well as permanent plants for such a purpose, they are so exceedingly apt to become smaller by degrees and beautifully less. The *Gladioli* *psittacinus* section are the best permanent border kinds, and these will, in good soil, grow into large bunches like the *Tritomas* and *Schizostylis*, but of course they have not perennial foliage. *Gladioli* and *Lilies* would, no doubt, thrive best amongst dwarf-growing shrubs where manure could be given, and the soil and bulbs could be renovated as needed. When the tall spikes and heads of bloom of these bulbs are seen projecting just above a dense growth of foliage, they look far more pleasing and picturesque than would be the case if the soil were simply carpeted with one carpet plant. For all general carpet purposes I prefer the Sedums. A. D.

Tropæolum speciosum.—In order to insure success with this fine scarlet-flowered climber, it should be well established in pots

before it is planted out, and during growth water should be freely supplied. It succeeds best in well-drained rich soil.—D.

ALPINE PASSES AND ALPINE FLOWERS.

ONE of the great delights of Swiss travelling, one of the pleasures which draw people, year after year, to the land of snow and alp, is the never ending interest which Alpine flowers afford. People sometimes wonder how I can set off alone for a long day's ramble, over a pass or up a mountain side, with no baggage but my knapsack and no companion but my "stock," but such people know nothing of Alpine flowers and of the deep, pure pleasure which they give. Loneliness with them is out of the question and cannot exist, and when I walk afterwards round my rock garden at home, and see the plants which I gathered growing there, often as perfect as in their native haunts, the walk and the scramble come back to my mind, and I take my walk over again. In this old-fashioned winter, when our garden treasures are still buried in snow, an account of one of these walks may not be uninteresting. On the 27th of August last I left the bustle of the Steinbok Hotel at Chur, and the crowd of tourists, struggling for places in the dusty diligences,

a sort of protection from the heat, their black and cream-coloured coats contrasting well with the white glitter of the snow. The descent to Davos was easy, and with the exception of more patches of *Saxifraga cæsia*, as luxuriant as those at the foot of the pass, and here and there a root of *Viola calcarata*, I saw nothing remarkable among the many Alpine flowers I met with.

The next day, after a pleasant rest at Davos am Platz, I set off, a little after seven, for Bergün by the Sertig pass. A well-defined path led for some distance by the side of a torrent, through the wooded Sertigthal, to Dörfli, and then up the Kühhäppli to the head of the pass. As the latter name denotes, herds of cows were feeding at intervals in the valley as far as the alp extended. Up to this point I met with many good flowers, such as *Potentilla ambigua*, *Gentiana excisa*, and *Phyteuma hemisphericum*; above it the path ceased, and I lost some valuable time, which should have been spent in collecting, in trying to make it out. One of the first rarities I met with was *Primula Candolleana* growing in low fissures of rock right in the bed of a stream, and partially covered with water; with it I found the round-headed cotton grass, *Eriophorum Scheuchzeri*;

then, as I ascended the pass I came on *Senecio abrotanifolius* in splendid bloom, *Achillea nana* and *Hieracium albidum*, a plant which always pleases me with its fragrant scent and large straw-coloured flowers, and which I am always surprised at not finding in the published lists at home. Its leaves and stem are sticky, like the sweet *Salvia glutinosa*. Higher up, *Soldanella minima* reared its beautiful fringed bell among patches of blue *Gentians* (*verna* and *bavarica*) and the pink Alpine *Treffoil*. Still higher appeared *Ranunculus rutæfolius* and *montanus*, and, highest of all, the red and white varieties of *Ranunculus glacialis*—a plant which, unfortunately, can never be seen in perfection away from its native haunts—and, loveliest of Alpine gems, *Androsace carnea* and *ciliata*. At some distance before reaching the top of the pass, vegetation ceased, and nothing could be seen but a confused mass of stones and boulders with patches of snow at intervals, and nothing heard except the occasional cry of some wild bird and the warning whistle of the marmot. From the summit, 9062 ft. above the sea level, a glorious view of Piz Ketch and the Porchabella glacier presented itself, while just below glittered the clear green waters

Asphodelus ramosus in the Wild Garden.

of the Raveisch lakes. By the side of these lakes, bearing to the right, over Alps laden with flowers, amongst which I gathered *Pedicularis tuberosa* and *Nigritella angustifolia*, my path lay, and before long I reached the head of the Val Tuors, and descended in safety to Bergün on the *Albula* Pass. One word in praise of this beautiful Swiss village. Travellers are in the habit of rushing through it, either by diligence or carriage, as quickly as they can, anxious to find quarters in the hotels of St. Moritz or Pontresina, but if they could only be induced to stay here a day or two and explore the adjacent country, they would not repent it, for the walks around are beautiful. As I sat in the balcony of the Piz Aela Hotel, in the centre of the village, watching the setting sun, a storm came sweeping up the valley from the south, and as peak after peak became shrouded, and others stood out in bold relief against the black bank of clouds, the most beautiful effects were produced, and I was confirmed in my opinion that Bergün, with its picturesque houses and quiet people, and, above all, its magnificent mountain view, is without doubt, one of the loveliest spots to be found in al Switzerland.

F. M. BURTON.

Highfield, Gainsborough.

then, as I ascended the pass I came on *Senecio abrotanifolius* in splendid bloom, *Achillea nana* and *Hieracium albidum*, a plant which always pleases me with its fragrant scent and large straw-coloured flowers, and which I am always surprised at not finding in the published lists at home. SUB-TROPICAL GARDEN PLANTS.

AMONGST the many plants brought into notice of late years, far too large a portion are of but little value to the cultivator as regards making pleasing effects in glass houses during the winter. I will therefore point out how this defect may be remedied by making selections for the sub-tropical garden. The *Aralias* form a fine class, but of these, with the exception of *A. Sieboldi*, *A. S. variegata*, and *A. papyrifera*, one sees but few representatives. *Aralia umbraculifera*, when well grown, makes a good isolated specimen, so does, also, *A. trifoliata*. These are both greenhouse kinds, and when taken up, at the approach of frost and carefully potted or tubbed, they are effective subjects for rooms or staircases, or conservatories. They may be increased without much difficulty from cuttings; but, perhaps, the quickest mode of propagation is either root-grafting on *A. papyrifera*, which roots like a Willow, or else striking the latter from pieces of the root, allowing the plants to grow for a season, and grafting them above ground. *Aralia spinosa* is a handsome, hardy species, which makes a fine group or single specimen; it may be increased by means of root cuttings taken off in the autumn and struck without heat. The *Gastonias* allied to the *Aralias* are equally useful subjects, and require the same culture as the greenhouse *Aralias*. The red-leaved *Dracenas* are not so suitable for planting out as the green-leaved sorts, as they seem to suffer much more from wind and sun, and soon get a dilapidated appearance. *D. braziliensis*, with broad, handsome, bold green foliage, is a plant of robust constitution, which cannot be said of the red-leaved kinds. *D. congesta* and *D. rubro-marginata*, both graceful sorts when tall, blend effectively with the larger forms of vegetation in garden landscapes. *Pandanus utilis* is a grand subject, but it is better not to plant it out, but merely to sink the pot or tub below the surface of the lawn. *Ficus imperialis* and *F. Leichtensteini* are easily managed warm house plants, which make fine specimens if planted out in good ground. They lift well, and, if kept close for a few weeks, make useful subjects later in the year. The *Metrosideros* is not nearly so much cultivated as it was fifty years ago; *M. albicans* is handsome both in flower and foliage; *M. coccinea* and *M. alba* flower profusely during the summer, and in winter too; they have all the peculiar bottlebrush character of blossom to be found in so many New Holland plants. They make striking plants on Grass plots in sunny situations, and may be planted out in a mixture of sandy loam and peat. *Cineraria platanifolia* is effective, although somewhat coarse in foliage; it should, therefore, be planted at some considerable distance from the eye. It produces enormous panicles of yellow flowers in January and February.

The different sorts of *Amorphophallus* make pretty objects if five or six be planted somewhat closely together; singly, they might be considered too stiff and fungus-like; *Philodendron lacerum*, *P. pertusum*, *P. cordifolium*, in warm nooks have quite a tropical appearance; they look well creeping on the ground, or clambering on large trees. In Southern England they may be planted out, or may be grown in pots, but if they have much nourishment they become far too rampant in places where the accommodation is limited; like most half epiphytal subjects the *Philodendron* is easily increased; *Tradescantia discolor* makes a peculiar but telling border to a bed of fine-foliaged plants. All the *Alcascias* and *Calocasias*, such as *odora*, *nymphæfolia*, *violacea*, and *gigantea*, are beautiful objects in shady or half-shady quarters; they require rich, friable soil and plenty of water. The *Habrothamnus* and *Cestrum*s, such as *H. fasciculatus* and *C. aurantiacum*, make graceful objects either planted out or in tubs. These plants were once very common, but they have succumbed to the fashion of the day. *Curculigo recurvata* and *C. recurvata variegata* may be made of much use in single groups, or mixed with other tropical subjects. That grand tree *Paulownia imperialis* may be also made to do duty in a more humble way in the sub-tropical garden. Propagated from ripe wood, precisely as in the case of Vines, one can have plants 8 ft. or 4 ft. in height the first season, and in the following year they will be, if thinned out when standing too thickly, from 8 ft. to 10 ft. high, and will be covered with fine foliage. In order to obtain perfectly ripened wood of a *Paulownia*, a specimen may be planted in a chink of the greenhouse floor, and trained as a roof or wall creeper. It

will make but little growth, but the wood for propagating purposes will be far superior to that from trees out-of-doors. *Kölreuteria paniculata*, *Amorpha fruticosa*, and *A. nana*, when cut down to a stool, annually produce a quantity of beautiful feathery foliage. In making use of all or any of the above-named plants, the cultivator will be guided but little by the prevailing mode of ribbon border, or bedding arrangements; on the contrary, he must use his skill and taste as a garden artist in forming those pleasing combinations of light and shade, form and colour that give in a well-finished picture a lasting and pleasant impression.

SYLVESTRIS.
Moravia.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Salvia splendens.—Now that the period of flowering is about over with this plant, I should like to impress upon those who have a good stock of it, and usually consign them to the rubbish heap, the desirability of keeping them till all danger of frost is over, and then planting them out either in groups or mixed beds for an autumn display. Treated in this way, the effect produced by them is quite striking. We had a mixed bed of these and *Chrysanthemum frutescens* last year which was much admired, the bold masses of the scarlet *Salvia* being toned down by its more delicate neighbour the *Chrysanthemum*. *Fuchsias* of different colours may be used for bordering the bed.—A. HOSSACK, *Ragley, Alcester.*

Strobæa purpurea.—I am pleased to learn, on such good authority, that this plant is fully entitled to be designated hardy, and that, in some parts of the kingdom at least, it requires no more attention than hardy herbaceous plants generally. Nevertheless, I think I was justified in recommending a little caution in dealing with a comparatively untried plant. I had been assured that it was hardy in a certain place, and I did not doubt it; but remembering the comparative mildness of recent winters, I would not say that it was hardy. Possibly it may prove as hardy in all soils and situations as *Koiphonia Uvaria*, a well-known South African plant. This winter will try the constitutions of many so-called hardy plants. Many plants that are perfectly hardy on the south and west coasts succumb to the cold and wet of ordinary winters a few miles inland, and the nature, as well as the condition as to moisture, of the soil is an important factor. Mr. Elacombe, in a recent number of THE GARDEN, suggests that persons sending lists of their losses or gains should give their addresses, and I would further suggest that they add a few words respecting soil, subsoil, situation, and aspect; then their record will have a real and permanent value. I am not of the opinion that we should plant nothing except perfectly hardy subjects, but it is of great importance to know their degree of hardiness in different localities and situations, and under diverse conditions. We have not, for instance I believe any evidence respecting the hardiness of *Strobæa purpurea* in the midland and northern counties.—W. B. HEMSLEY.

Signs of Spring.—These are, as yet, not very evident out-of-doors, but within the hardy plant house the crowns of *Primroses* are awakening and pushing up leaves, and the trusses of bloom already show tinges of colour. *P. denticulata* and *P. purpurea*, almost the earliest and most pleasing of all for the house, will soon be in bloom, and how beautiful they are! *P. farinosa* is producing mealy foliage white and pretty; *P. nivalis* will shortly display its pure white trusses of flower, and *P. intermedia* those of rich, deep red. *Auriculas* have passed through the dormant stage; the pale yellow leaves have been pulled away, the surface of the soil has been neatly dressed, and the crowns are now expanding their youthful leafage. Polyanthus of the self and fancy-coloured kinds are pushing up bloom; so, also, are the Snowdrops, Squills, and Cloth of Gold Crocus; whilst many-hued Hepaticas are bursting their crowns, and exposing a trace of pretty tints within; on the trellis and walls Tea Roses are pushing their buds, whilst outdoors they look as if withered up. *Marschal Niel*, ever the earliest, as it is the best, of all evergreen Roses, is making new shoots, and a few days of sunshine will greatly encourage them; indeed, there is scarcely a plant in the hardy house that does not show that the shortest day is passed, and that "the winter of our discontent" will soon be over. How much better to have all these in a house needing no heat, than to see a house, supposed to be frost proof, full of tender plants half dead and frost bitten.—A. D.

Sweet Peas.—Flowers of these are always valuable in an out state in summer, and, where they are required at that season, now is a good time to sow the seed. A moist situation and a deep soil should be chosen for them; they will then bloom in profusion for months in succession.—S.

PLANT CULTURE FOR MARKET.

PRIMULAS.—The red and white kinds of the Chinese Primrose are grown in thousands by London florists. Some grow them for sale in the shape of plants; others for the sake of their seed, which, if it come from a good "strain," is valuable. The practice adopted by the best growers is as follows: Three sowings are made; one early in March, a second at the end of April, and a third towards the end of May. Seed sown in March produces blooming plants in October and November; that sown later at Christmas and onwards. The seed is sown in shallow boxes, which are better than pans, as they do not absorb the moisture round the edges. It is sown on well-rotted manure, previously well moistened, and then slightly covered with silver sand. A piece of brown paper is placed on the surface of the box, which is never allowed to get dry until the seed has germinated, after which it is removed. The boxes are placed in a warm temperature and in a shady position. When the plants are large enough to handle, they are pricked off four or five together into a 4-in. pot, and, when they have made good roots, they are potted singly in 5-in. and 6-in. pots. Whilst growing, they are kept rather close and are sprinkled overhead several times a day in bright weather. Discrimination in watering is necessary, as, by using too much or too little, serious injury is the result. If the plants show blooms early in the autumn the latter are picked off, so as to give strength to the plants. The best situation for Primulas whilst they are growing is a north house or frame, where plenty of light but not much sun can reach them. When the roots are pot-bound, a little weak manure water is given them and no more fire-heat is applied than is sufficient to keep out damp. Plenty of air night and day when the weather is favourable is given in order to render the plants dwarf and stocky. The soil used for Primulas is well-rotted leaf-mould or cow manure mixed with equal parts of mellow loam and a little silver sand. Good drainage is always necessary, and, under the above treatment, fine bushy plants, bearing large heads of snowy-white or rich rosy-red blossoms are produced. When grown for seed, all the weak blooms are picked off, leaving those only which appear to be likely to produce plump seed-pods. The plants are arranged on large stages in lean-to houses, each colour being kept in houses at a distance apart, in order to prevent cross-breeding, which would spoil the "strain." Great attention is paid to watering and ventilating after the plants have formed their seed-pods, and during very hot sunshine a little shade is afforded them.

The double white Primula is grown chiefly for the sake of its blossoms, plants of it being in little demand, and, moreover, they are too difficult to grow so as to be sold at reasonable prices. There have been many new kinds raised, but the old form is still found to be the best for winter; its blooms are used largely both in button-hole and ball-room bouquets. The most successful grower of double Primulas with whom I am acquainted is Mr. Reeves, of Acton, who has a large house wholly devoted to their culture. It is span-roofed, with a path through its centre and a 6 ft. bed on each side. On these beds are arranged upwards of 3000 plants in 6-in. pots. The plants on one side of the house are always in bloom, while those on the other side are coming on to succeed them. When one side ceases blooming, the plants are cut down, cuttings are put in, and most of the old roots are thrown away; then, by the time the other side of the house has done blooming, these cuttings are sufficiently advanced to keep

up the succession, and this goes on year after year; indeed, visit this Primula house when one will, one side of it is always a sheet of snowy-white blossoms. Double white Primula flowers fetch from 12s. to 20s. per dozen bunches, and plants realise from 10s. to 20s. per dozen, but cut flowers are by far the most remunerative. The soil principally used for double white Primulas is fibrous sandy loam without any manure whatever, as, when the latter is used, the growth made is vigorous but soft; the crowns do not get well ripened, consequently they are liable to damp off in winter. A dry, airy atmosphere and careful attention to watering are the chief points to be observed in their after culture.

CAPE HEATHS.—Probably as large quantities of Heaths are disposed of about London as of any other kind of plant. One grower alone sells yearly 200,000 plants, and I believe some grow even more than that number. The large houses devoted to Heath cuttings in some nurseries during winter are alone a sight worth going miles to see. Here, on stair-like stages, are thousands of 6-in. pots, each containing some fifty cuttings, covered with small bell-glasses. In sheds adjoining may be seen men making cuttings with pairs of scissors and others deftly inserting them in the pots, which are surfaced with finely-sifted silver sand; others, again, are watering and setting the pots in their places and putting on the bell-glasses, whilst others are removing such as are already rooted to make room for those that are newly inserted. More men may be seen out in the grounds busily nipping off the points of young plants which are growing on in cold pits for the next year's blooming, and so the production of young Heaths goes on from year to year. About Christmas time the markets are crammed with little bushy plants of the rosy-coloured *Erica gracilis* and the pearly, rose-tinted, waxy-blossomed *E. hiemalis*, two of the principal varieties grown for winter and spring blooming. These are succeeded by *E. Willmoreana* and *E. candidissima*, and after these come the beautiful *E. ventricosa* and the yellow *E. Cavendishi*. Cuttings of these *Ericas* are struck on a very slight bottom-heat during the winter months or as soon as cuttings of them can be obtained. When rooted, they are potted off, three in a 3-in. pot, and placed in light, airy situations, such as on shelves of houses or in lean-to pits close to the glass. During March they are shifted singly into 3-in. pots; and, when well-rooted, they are placed in cold pits and subjected to as much light, air, and sun as possible; in this state they remain throughout the summer, receiving abundance of water both overhead and at the roots. In the following winter they are cut back, and as soon as they again break into fresh growth they receive their final shift into 5-in. pots, extra large plants being potted in 6-in. ones. Pure peat and sand constitute the kind of soil used for them, and they appear to enjoy it, for Heaths may be seen in some nurseries growing as freely as scarlet Pelargoniums. Fire-heat is as much as possible at all times avoided, and in very severe weather mats, &c., are used to keep the plants at a proper temperature in preference to heat from hot-water pipes.

FUCHSIAS.—These are everybody's plants, and the market is seldom without them. In July fine plants laden with blossoms may be bought in the thoroughfares at 6d. each. One would think it could not pay to grow Fuchsias for the price which they fetch, but it is the quantity that pays, good plants, and well flowered, being turned out in three months from the time when the cuttings are put in. Some growers get their principal batch of plants into flower early in April, when they are the most valuable. They

are struck in autumn for spring blooming, and in spring for the summer and autumn supply. The cuttings are inserted thickly in 6-in. pots, and, when well rooted, are shifted singly into 8-in. pots; when again established, the shoots are cut back, so as to induce the plants to grow bushy, and when the pots which they occupy are filled with roots they receive their final shift into 5-in. or 6-in. pots. Each plant is supported by a central stake, to which the branches, when in bloom, are tied in such a manner as to form a perfect but by no means formal pyramid. Rose of Castile, Mrs. Marshall, and Arabella are the chief light-coloured kinds grown; the dark-coloured varieties are War Eagle, Wave of Life, Catherine Hayes, Souvenir de Chiswick, and other free-blooming sorts.

BALSAMS.—These are always abundant in London during summer and autumn, and, although they are sometimes hawked about the streets and sold at very low prices, they are, nevertheless, remunerative. Balsams are but a very short time on hand, for in three months or less good saleable plants can be obtained. The seed is sown in heat in spring in boxes or pans, and the seedlings are potted off and grown on in warm houses, plenty of manure water being given them at the roots, and copious syringings of clear water overhead to keep down red spider and to promote free growth. They are very impatient of drought, and to timely watering alone is due success in their culture. Some plant out their Balsams in an open border consisting of rich soil in June, and take them up and pot them just before flowering, but this is not a good practice. Market gardeners seldom aim at what may be termed novelties in Balsams, those sorts with a good habit and bright self-coloured flowers being generally preferred by them, and, although nothing very striking in the way of beautifully striped flowers is to be found amongst them, yet, if lovers of Balsams were to watch the plants so abundantly brought to Covent Garden during the summer and autumn, they would probably note the wonderful results in the way of both growth of plants and profusion of flowers obtained in 5-in. and 6-in. pots. The principal, or what may be termed the orthodox, colours to be found in market plants are wholly white and scarlet, or these two colours intermingled in spots and stripes.

C. W. S.

THE FROST AND VEGETABLES.

THE long-continued frosts have hit these harder than I ever remember. Until within the past fortnight, during which the severe frosts have called in the biting east wind to assist them in their work of destruction, vegetation seemed to have sustained little injury. There seems several causes for this. The frosts were severe, but the air was still. Vegetation was pretty well protected by snow. Hoar frost was also more developed, and continued longer than usual. All this helped plants in general and vegetables in particular, to pull through; but within the past fortnight the wind remained steadily in the east, and there have been several days when the atmosphere was driven against every living thing by a strong east wind, with a penetrating force that threatened to pierce even hearts of Oak, and a cold equal to ice and salt at their worst. These have literally killed thousands of vegetables and crippled all. Our plantations of old Cabbages, always left to provide any quantity of Coleworts in the spring, seem dead to a stalk. Brussels Sprouts, Savoy, and even Scotch Kale are severely crippled. All our Broccoli lies flat on the ground, as if trying to hug the remainder of the snow that protected it so well during the first stages of the frost now nearly two months ago; and even Leeks, that I have never seen browned before, look as if fire had passed over them. A visitor, from a distance more favoured, where the snow has disappeared, assured me that the frost seemed to have killed the Grass. The entire lawn was as brown as if it had been scorched up by drought at midsummer. This similarity of appearance and results from frost and sun or fire is familiar to cultivators. Our Grass continues covered, and so far safe; but the loss

and injury to the vegetables is a very serious matter, and this wonderful persistence of the cold is almost equally so. Most of the trees and shrubs yet seem safe, though how long they will continue so, with the wind fast in the east, and the snow lingering for a farther supply, no one can say. The winter has tried most severely even the largest Pampas Grasses, and killed all the smaller ones that were not protected. Tea Roses are also severely hit; Maréchal Niel looks as if it would hardly recover, and Safrano seems to have suffered almost as much. But it is quite premature to note the losses caused by the frost; this cannot be done till the thaw comes. Not a few plants that make no signs of distress while frozen die soon after they are thawed, and, on the other hand, those that shrink and shrivel the most under the cold grasp of the frost often suddenly and completely revive, with little or no permanent injury, on the return of genial weather. The sun, as if weary of looking out on a frozen world, and despairing of its power to chase away the cold, appears to have retired altogether, and left the leaden skies and the frost to do their worst in the garden. I never remember such a continuous and marked absence of sunshine. Being so long without sunshine, it is to be hoped it will not now return till after the thaw, for all experience proves that rapid thawing during bright sunshine often does as much or more injury to vegetation than severe freezing or long continuance in a frozen state.

D. T. FISHER.

TOBINS' SYSTEM OF VENTILATION.

THE subject of ventilating glasshouses is itself being again freely ventilated. As only a certain quantity of air can be confined in a given space, if it can be shown that outside air is undoubtedly introduced into a closed room or plant house, it follows that the air already confined must find for itself some means of egress. Ordinary ventilators are often erroneously opened with the idea of letting out hot or vitiated air, instead of which the pure and cold air rushes in through the aperture with the usual result of a draught, and the hot air finds its exit elsewhere. The same process takes place with the system I desire to advocate, but with the important exception of perfect freedom from draught. Fresh air can be introduced into houses without any perceptible draught by boring a round hole of about 2½ in. to 3 in. in diameter through the outside wall just above the ground line, and fixing in the house by means of a zinc neck, an upright tube of the same material and diameter and about 5 ft. high at least. Curiously the cold air confines itself to the shape of the tube until it strikes the ceiling or glass roof, and then imperceptibly disperses, and can be stopped at any moment by covering the inside orifice with a cap attached by a chain. I drew attention to this, ordinarily called Tobins' System, in your paper of April 8, 1876, without any apparent result, and conclude that prejudices prevented a trial, or that it has been tried and found wanting. If the system does not answer it would be an act of kindness for some of your ventilating authorities to say so, but if it has not been tried they will perhaps give it their attention, and then furnish us with their experience. Neither expense nor appearances can be any objection, because half-a-dozen tubes can be put up in out-of-the-way corners for a few shillings, and be taken away again if not liked. I find it a perfect remedy for the stuffiness of an ordinary sitting-room.

Uabridge.

J. L. OLIVER.

Potatoes Dormant.—I have rarely known Potatoes to be in such a dormant condition as they are now; except when kept in close, heated places, not a tuber has started into growth, and there is now no prospect that they will be unduly excited before planting time. This will be an undoubted gain as it is very difficult in mild seasons to keep sprouting in check. In the case of early Kidneys that are to be planted in pits or frames or in warm borders, it is well to subject the tubers to a gentle warmth, just enough to start the eyes, as then it can be seen that none are "blind." Where this is done the tubers should be kept in the light, and then the young shoots will be plump and strong. With tubers planted early in the open ground it is, no doubt, best that the growth there should be excited only in proportion as the soil becomes naturally warmer, and where this is the case the crop is not likely to be cut down by late frost. It will be unadvisable to plant too early this year, as the ground will be exceedingly cold for some time, let the weather be ever so favourable. For all main crop purposes the first and second weeks of April is early enough, and, indeed, in most soils any time during the month of April will do. There are a few new kinds put before the public this year, and, so far, only one new American, called Pride of Ontario, of which nothing at present is known. For general crop purposes, however, Snowflake and Early Rose remain the most popular of all the American sorts.—A. D.

NEW OR RARE PLANTS.

BOMAREA OLIGANTHA.

This plant was discovered by Mr. B. Roehl in the Peruvian Andes, and its seeds were imported and raised by me at Baden-Baden. When the first little bunch of two flowers appeared, I was anxious to have the plant named by competent authority; therefore I submitted it to Mr. Baker, of Kew, who pronounced it to be new, and named it *B. oligantha*. The specimens submitted to Mr. Baker were, however, taken from small plants cramped for root room, a fact of which Mr. Baker was not aware, and hence he gave it the not quite appropriate name which it now bears. One plant grown in a large pot, and another planted out, became fully developed, and have produced since July last a succession of blooms, with still some buds remaining to expand. During summer and autumn the flowers assume a much brighter hue than they now possess, the outer segments assuming a colour like that of Papaver

Bomarea oligantha.

bracteatum. It is of very easy cultivation, only requiring space in which to grow, and a soil consisting of peat, loam, and sand, intermixed with some rotten manure. The plant will now go to rest for a month or two, when it may be placed in a greenhouse in which a temperature of 36° Fahr. is maintained, or just enough to exclude frost. During the growing period it wants a good deal of water, and therefore, when grown in a large pot, it must be efficiently drained, taking care, however, not to use any sharp-edged crocks, because the Bomareas, before going to rest, form egg-shaped tubers on thin threads, which go down to the bottom of the pot, imbedding themselves in the crocks, and, consequently, are liable to get injured by sharp edges, an injury which may cause the decay of an entire plant.

Baden-Baden.

MAX LEICHTLIN.

Hamamelis arborea.—This may be added to Mr. Groom's list of shrubs (p. 84) which defy the present severe weather. Its starry yellow blossoms are very bright and pretty just now, and they seem quite indifferent to the biting east wind which keeps back even

the Snowdrop and winter Aconite. I had my little tree from Messrs. Rodger, McClelland, & Co., of Newry, and in the course of a few more years I hope it will be quite an acquisition in the winter garden.—H. EW BANK, *St. John's, Ryde*.

THE FRUIT GARDEN.

SAUCERS OF SOIL v. SAUCERS OF WATER FOR FORCED STRAWBERRIES.

I CAN, after years of experience and a fair trial of both plans, recommend saucers of soil for placing beneath the pots in Strawberry forcing in preference to empty saucers, and they should be used from the beginning; that is, from the time when the plants are started. As Strawberry forcers well know, plants set upon dry airy shelves in forcing-houses soon become dry at the root when the longer and drier days of March, April, and May come on, and require frequent waterings—sometimes two and three times a day; hence recourse is usually had to saucers to hold a reserve supply of water—a reserve which during dull weather is an evil, as the plants do not need it, though in bright dry days they will absorb what water they receive in the pot and the full of the saucer besides; at least the water goes away by evaporation and through the plant together. All the trouble and bad effects of this practice are, however, avoided by filling the saucers with good soil, and placing them under the plants at the beginning. The first thing we do here is to fill the saucers, which are of a size in proportion to the pots and have a hole in the bottom, over which one crock is placed, and when they are all set on the shelves or wherever the plants are to be started, the latter are set upon them. But before doing so, the holes in the bottoms of the pots are examined and enlarged a little if necessary with the pointed claw of a hammer to let the roots out easier. I have just been looking over some hundreds of plants to-day which are throwing up their flower trusses and find, as usual, that the fresh, new roots have already taken possession of the soil in the saucers to such an extent that when a pot is lifted up the saucer nearly clings to it. These roots have not been encouraged by bottom heat, the plants stand on a stage in the Strawberry house, and anyone may judge what an advantage it must be to the plants to have such a quantity of fresh roots to draw upon, and which they could not have by any other means. The result is, always having crops of good fruit without using a drop of liquid manure of any kind during the forcing season, while the plants seldom or never need water more than once a day during the driest weather. The soil in the saucers consists of pure sifted loam and sand, to which has been added a good sprinkling of Standen's manure, the best stimulant for Strawberries and pot Vines with which I am acquainted. The soil in the saucers never gets dry, as it is not exposed to evaporation like the ball of soil in the pot, consequently the plants are never in danger of flagging in hot weather. The fact of the matter is, that though the rooting through the bottom does not in the least check the activity of roots in the pot, the main roots are in the saucer by the time the fruit begins to swell off, and when the plants are finally turned out, the saucer is a complete mass of young, healthy shoots. It is an old practice of good Strawberry growers, I am aware, to set the pots on turves placed on the shelves, which amounts to much the same thing as the practice I recommend, only, that it is seldom convenient to use the turves as they entail the necessity of leaving the plants in the same place till the end, or of sacrificing the roots in moving them, whereas it is a perfectly easy matter to move the saucers along with the pots, as we have to do with any batch of plants that are forced.

J. S. W.

BEST STRUCTURES FOR PINES.

ABUNDANCE of light—one of the first essentials in the culture of the Pine-apple. Wherever the plants receive the most light and for the longest period every day there you will always find the largest, most robust and best matured plants. It follows, therefore, that that kind of structure which admits the greatest quantity of light must be the best for the purpose, and the structure which does this is a span-roofed one running north and south. On a house of this kind

the sun, about midsummer, shines for sixteen or eighteen hours every day unless it is shaded by trees or other objects, which it should not be; whereas a lean-to or hipped-roof house does not receive the sun's rays fairly for much more than half that time. The difference to the plants may, therefore, be estimated. I have grown Pines in very different structures, from old-fashioned houses built more than seventy years ago to modern span-roofed ones glassed with wide panes on all sides, and nothing has ever struck me more than the difference in the plants in the different houses. Here we for a long while grew a portion of our plants in a low but light lean-to pit, and the others in a span-roofed house standing north and south, and it was only too noticeable as regularly as the autumn came round that the plants in the span-roofed house were always the best by a long way, though otherwise treated exactly alike, and consequently the latter were always selected for early fruiting kinds. I would prefer a lean-to house for winter fruiting sorts, because such a house gets all the sunshine that is going at that season and economises the heat best, but for growing plants in, or for fruiting the plants at any other period of the year, a span-roofed house is the best. Only those who have cultivated Pines under different circumstances, as regards houses, can fully appreciate the difference which plenty of light all round makes to the plants. I remember talking on this subject to Mr. Ward, of Bishop's Stortford, (who has, perhaps, produced heavier Queen Pines than any grower in England) on one occasion when we met as competitors in the Pine-apple class at Manchester, and he remarked to me that if he wished to give a Pine plant every chance possible, he would plant it in a span-roofed house and give it as much room as would allow one to walk all round it, so much importance did he attach to giving the plants room and light, and although Mr. Thomson, author of "Culture of the Pine-apple" grew his finest Pines at Archersfield in old-fashioned lean-to pits, he was fully sensible of the advantages of light, and says, in his book, that in our climate Pines cannot possibly have more light and sun than is necessary, and that Pineries should therefore be constructed so as to admit and diffuse as much light and sunshine as can be had, and the kind of house he recommends for the purpose is a span-roofed one, except for winter-fruiting kinds. Mr. Baines (p. 52) says fresh loam is the only soil suitable for Pines, a statement which is very far from being correct. Mr. Miles, of Wycombe Abbey, grows his Pines in yellow loam of a fine silky texture, but here, the loam, though suitable for many things when used alone, does not suit Pines till it is mixed with one-third or more of peat and sand, and in this compost we grew our Pines always, and had always plenty of fruit both large and good. But at Broxmouth Park, near Dunbar, the seat of the Duke of Roxburgh, we many years ago saw a houseful of fine healthy Pines growing in pure peat, and the fruit was so good that it was thought worthy of appearing at the Edinburgh Show, and, if I remember rightly, it received a prize. Now between peat and loam there is much difference, chemically and mechanically, and, between the two, no doubt suitable composts could be prepared according to any one's needs.

Wortley.

J. SIMPSON.

VINE CORDONS IN FRONT OF WALLS WITH A SOUTHERN ASPECT.

ALTHOUGH Grape growing occupies a foremost place in fruit culture in England, it has not as yet succeeded in placing the Grape within the reach of the middle classes in sufficient quantity and, consequently, at a price that can be afforded by them. There is the possibility of producing good useful fruit (not exhibition bunches) of early sorts on cordons. The best place is probably in that space of 6 ft. at the foot of south walls, usually occupied, in part only, by Peaches, Nectarines, and the like. There is no more reason why the Vine should not do well in company with these than that undergrowth should not exist under timber. That they do well under such conditions is a matter of fact. The first row may be 3 ft. from the wall, and the second 6 ft., the plants being set out alternately. In the second year after planting, if good canes be selected, the Vines may be cut down to about 1½ ft. from the ground, just as Willow stools are created. The canes may be lightly bundled together, and brought over—the back row to the front wire, and the front row to the hinder one; by this means but little shadow will be thrown on the fruit-bearing parts. When the plants are strong, and produce a quantity of shoots, four or five of the strongest may be selected, all weak ones being cut away; and each year, early in spring, they may be cut back to two eyes each. The after cultivation is simplicity itself, consisting of stopping the main shoots at 4 ft. in length, removing all tendrils and weak unfruitful shoots. The ground may be mulched with clean straw, so that the bunches may be kept clean. Thinning out the bunches is not necessary. Such Vine stools produce annually from ten to twenty bunches, and, as they grow under quite natural

conditions, they are not exhausted in twenty years. It is not an uncommon thing for 200 plants to bear between 2000 or 3000 bunches, and that, too, without fire-heat, syringing, or any watering whatever.

Moravia.

SILVESTRIUS.

PLATE CLXV.

NEW CAPE HEATHS.

HEATHS have a charm for every one, and yet for many years past they have not received the attention which they deserve, simply because they are somewhat difficult to cultivate, and do not grow into large specimens in a single year. The difficulty, however, is more imaginary than real, and I venture to assert that any one regarding the attentions bestowed upon their plants as a labour of love and not in the light of a task, will certainly succeed in producing good healthy specimens. But even supposing Heath cultivation to be surrounded with the amount of risk that many assert pertains to it, it is not creditable to cultivators to have given up the task in the manner in which it has been done. Happily the demand for good varieties of this class of plants is again in the ascendant, and therefore it has been thought desirable to give illustrations of some fine hybrids which have been produced and recently sent out from Messrs. Rollisson's establishment at Tooting, a firm long famous for this class of plants. The varieties in the annexed plate can all be recommended for vigorous habit and free flowering, and at the same time they are thoroughly distinct from any other species or varieties hitherto in cultivation. They may thus be briefly described. *E. obbata cordata*, a beautiful, free, large-flowering variety which, if grown under glass, is a pure shining delicate white, but if a tinge of rose or flesh colour be considered an additional charm, it can be obtained by exposure to the open air for a few days, whilst an additional point of excellence is that the flowers are entirely destitute of that peculiar gummy exudation so characteristic of the flowers of nearly all hard-wooded Heaths, and hence it retains its purity until the flowers die naturally. *E. opulenta*, habit robust and free, flowers produced in large whorls, the colour being a deep lake shaded with or crimson, limbs white and spreading. *E. effusa*; the flowers of this variety are large, and crimson-scarlet in colour, while the segments of the limbs are pale sulphur. *E. ornata* has flowers large and much swollen, colour at the base, rosy-carmine, the remaining portion being pure white, with the exception of a circle of green round the neck. *E. tricolor profusa*; the trusses and flowers in this variety are large, deep, rose-coloured at the base, shading upwards to flesh colour and ultimately white; an elegant variety of tricolor, and, as its name implies, an abundant bloomer. Fit companions to these, in order to make up a dozen varieties, are *E. Cavendishi*, *Massoni major*, *Thomsoni*, *obbata*, *jasminiflora alba*, *ampullacea major*, and *tubiformis*.

W. H. G.

GARDEN LABELS.

FROM what is stated by "S" (p. 91) I infer that to invent new kinds of plant markers is easier than to improve upon the old. I recommend those who require them first to determine what that quality is in the marker that they most desire. Is it appearance? What can be prettier than the terra cotta productions of Messrs. Maw? Is it durability? Those manufactured in zinc by Mr. Yeats, of Mortlake, are practically indestructible, and are also those which are made of sheet lead and have the name of the plant stamped on them. Is it that they may serve only a temporary purpose and last a few seasons only? Nothing can be more convenient than the wooden labels sold by Messrs. Blackitt at a price within the reach of most people who are willing to pay for such articles. These, however, as well as the zinc labels, are easily made, and the two processes are described in Vol. VII. of THE GARDEN (p. 397) and a considerable saving of expense can be effected if desired. Of the indestructibility of zinc labels and indelibility of the writing on them, I have sufficient evidence. I now send two specimens, which, as will be seen are quite legible, that I discovered this morning in some rubbish in an outhouse, and which I know were in use before the year 1851. They can be made of the clippings collected in the shops of those who work in that metal, and with a pair of shears can be cut into any form that may be required. On the subject of garden labels some very useful hints are given in Vol. X. (p. 237) of THE GARDEN.

B. S.

GROUP OF NEW ERICAS.

TREES, SHRUBS, & WOODLANDS.

HARDINESS OF THE HYDRANGEA.

THIS matter, in conjunction with that of its sometimes flowering blue, has, every now and then, been commented on by writers in gardening periodicals ever since such publications existed; and yet the plant seems as capricious as ever, more especially in regard to its flowering, while of its hardiness, I may say that about the largest plant of it I ever saw was growing in a garden fully exposed on a bleak situation in Northumberland, and that was more than fifty years ago; but I believe that this plant was much injured or wholly cut down to the ground in the memorable winter of 1837-38; nevertheless, it must have survived many winters anterior to 1825, when I first saw it, and it flowered well; but its blossoms were of the usual pink hue. The situation was a dry one, though extremely high and exposed; the soil, an open one, rested on yellow sandstone, large quantities of which were quarried for building purposes within 100 yards or so of where the Hydrangea was growing. At that time it was known that Hydrangeas sometimes flowered blue, but such as did so were supposed to be distinct varieties, a notion which has, of course, been since exploded; but I confess I have not been able to account at all times for the various caprices which the plant has shown under cultivation. Even but a very short distance from where I write, I can point to two plants growing in two cottage gardens only a few yards apart, one of them as good a blue as I ever saw, and the other a good pink; and I remember being very much puzzled by seeing at a horticultural exhibition, a few miles north of London, six plants in 8-in. pots producing beautiful blue flowers, and a like number in pots exactly similar that had bright pink flowers. As both came from the same place I felt surprised at this, as I have long held that the character of the water used for plants cultivated in pots has as much influence as that of the soil, and it is customary to use the same water for all kinds of plants. As a truthful exposition of failure is almost as useful as that of success, I will mention here one into which I fell many years after the one above alluded to; still it is many years ago now, but it was subsequent to the era in which it was affirmed that the change of hue in the Hydrangea was due to the presence of iron in some form or other in the soil. Well, being anxious to obtain blue flowers, and peat not being handy, I potted a few plants in the sandy substance which had dropped from an ordinary grindstone, judging that this must be charged as thoroughly with iron as any mixture could possibly be in a mechanical way, but the experiment was a failure, for though blue flowers were produced they were not of so good a colour as I expected; this was doubtless owing to the plants being watered with hard water from a well or pump resting on the limestone; perhaps the result would have been different if clear rain water could have been had, but the result, coupled with some other trials in which iron filings, &c., were used, puzzled me, and I confess not being at all times now able to account for the freaks the plant will take, for now and then we see both blue and pink flowers on the same plant, and, in the same truss, an inclination to present both hues. Certainly, the health of plants producing both colours is not so good as when only one kind is produced, but I am not in a position to affirm that one is any better than the other, as I have seen both equally vigorous. In a usual way Hydrangeas are very commonly met with in cottage gardens in the southern counties, but where they seem really most at home is in Devonshire; I well remember, when walking through the grounds at Mount Edgecumbe in that county, Mr. Pooley, the then gardener there, pointed out both kinds in the greatest perfection, and on the way from the kitchen garden to the mansion he pointed out a ditch as the boundary between the two; it had doubtless at one time been a sort of chasm formed by Nature, on each side of which soils of different characters had been thrown up—trees of most kinds thriving well in both, and there were many things growing there that were not at that time often met with out-of-doors; notably, I remember, a Eucalyptus more than 20 ft. high, but whether it was the one which of late years has been brought into notice or not I am unable to

say, but it was in a very sheltered position and evidently doing well. But to return to the Hydrangea: I should think it very seldom suffers from frost in Devon or Cornwall, although elsewhere in England I have been led to regard it of about the same hardiness as the Fig, and liable to be cut down to the ground in very severe winters. In other respects it resembles that tree also; both present a great amount of pith in the wood of the current year, and if another tree of similar habit be added to the list I would say *Paulownia imperialis* is the one. The Catalpa may be a little harder, and so may, perhaps, be the hardest Fuchsias, but as my object was only to speak of the Hydrangea I will go no further.

A RETIRED GARDENER.

RATE OF GROWTH AND QUALITY OF TIMBER.

ALLOW me to add a few more words on this subject, in order to place it in a more intelligible light, and also by way of an answer to Mr. Baines. The question between him and me is not really confined to the Wellingtonia, nor to home-grown timber alone, as Mr. Baines now states. He made no such exceptions in his first letter, but laid it down broadly as a rule "that the natural laws which govern the development of vegetable life in the formation of woody fibre pointed generally in one direction, which is that slow growth means comparative strength and durability." This, and this only, was the statement to which I took exception. Surely Mr. Baines does not mean to assert that the trees, whether exotic or otherwise, which are grown for timber in this country are governed by different laws from those to which they are subject elsewhere; this is about what his statements now amount to. Be this as it may, to the rule he gives for estimating the quality of timber I furnished several notable exceptions, which, according to Mr. Baines, are outside the question, but the real truth, I am afraid, is that Mr. Baines overlooked the array of facts which might be urged against him, just as he has been too hasty in his assertions about the laws which govern the development of vegetable life in the production of woody fibre. The explanation of the matter, so far, is this, as physiologists explain, and correctly enough, as any one can determine for themselves:—Plants are composed of two substances, the one cellular and the other fibro-vascular; the first is brittle and perishable, and the second strong and enduring. In the Raspberry, for example, we have wood consisting principally of cellular tissue, and consequently, brittle and perishable, and in the Hemp and Flax we have plants composed almost entirely of fibro-vascular tissue, and, consequently, tough and strong. Now these two substances vary in trees according to the rate of growth and other circumstances. When the tree grows fast it produces more fibro-vascular tissue and less cellular, and the contrary takes place when it grows slowly; and hence, in the first case, the timber is strong and tough, and in the last brittle and unenduring, a theory, it will be seen, that is quite opposed to that furnished by Mr. Baines. Other causes of strength and durability consist in the secretions deposited within the tissues. I do not know what the difference may be between the Oaks of Herefordshire and Westmoreland to which Mr. Baines alludes, nor does it matter in the smallest degree, but this I will assert, that the Oak which grows in the best soil and grows fastest will be superior to that which, through poverty or other causes, has grown slowly in the same locality. In making comparisons conditions must be equal. Until the fallacy of the theory now resuscitated by Mr. Baines was exposed by Knight, Lindley, Holt, and others, it was argued that because the Poplar grew fast and produced poor timber, so all other trees which grew fast must necessarily have the same fault; but, as Lindley points out, the Poplar is bad when it grows fast, and still worse when it grows slowly. Regarding the Admiralty Test Tables and others furnished by Lindley relating to fast and slow grown Oak timber, the following is an summary of the results tabulated: "The best (Oak) in quality was from Strathfieldsaye, and grew as much on an average as 1 in. in diameter annually, and all those others which grew above four-tenths in diameter were of good quality. On the other hand, all the slowest-grown timber in both tables was bad or indifferent." The Admiralty Tests are no sham, and these facts speak for themselves to any unprejudiced mind. C.

I was not unacquainted with the article from which Mr. Syme quotes, in order to make us believe in the quality of Wellingtonia timber, and which he says settles the question of its durability; but it most certainly does not, so far as my convictions go, even in that grown in its native country, and which has nothing to do with the subject at issue, for not until I have brought myself to believe all the exploits of the mythical Baron Munchausen can I consent to credit the story quoted. Allow me to be clearly understood in totally disbelieving this and similar statements, I do not for a moment question

any one's veracity, but I take most decided exception to their powers of observation or the data upon which their conclusions are formed. We are asked to believe that the trunk of a certain tree has lain above ground fully exposed to the weather 380 years and an unascertainable number beyond these; yet it bears no signs of decay in any part; and, in the other extreme, there are gigantic trunks of Silver Firs that, under like conditions, are every atom rotten in two years, and this in a Californian climate. Why, if the whole of the wood of these Silver Firs had been as soft and spongy as the bark of Taxodium sempervirens, they would not have reached a similar stage of rottenness if lying in the moisture-saturated tropics for the time. To ask any one who has had a fair opportunity for acquiring a knowledge of timber generally to credit this is an attempt to tax credulity to an extent that is almost amusing. But, when evidence such as this is adduced, it has only one effect, and that is to damage the cause which it is thus sought to sustain. When writing the first few lines on this subject I was not unmindful of the different species of trees that form wood rapidly, but which, nevertheless, is of good enduring quality; they simply are the exception which prove the rule, existent in this, as in almost everything else of a kindred character. Nothing that has yet been advanced by those who have attempted to make out that this was not substantially correct has shaken the facts of the case.

T. BAINES.

LOPPING DECIDUOUS TREES.

THE winter season is the time when this kind of work is usually performed, and a few remarks upon the practice from a general point of view may not be out of place. It is a subject which embraces a wide field, from the removal of a limited number of branches, which it occasionally becomes necessary to cut out of old trees that happen to exist in and about small gardens, to the wholesale lopping which we frequently see resorted to with hedgerow timber over large estates, and I may here observe that whether we look at the subject from the examples often practised on in gardens up to where lopping is carried out on an extensive scale, there is not a single operation connected with rural economy in this country wherein there is so little knowledge brought to bear, so much mischief caused in appearance, often irreparable in the case of small or comparatively small places, and so much real injury done to the look of the landscape, with no counterbalancing benefit to any one. I do not mean to say that under no circumstances should large or medium-sized trees have a portion of their branches reduced or cut out; this is very frequently not only admissible but necessary, provided the work be done with judgment. In medium-sized gardens and small pleasure grounds severe lopping, often to the extent of cutting the heads nearly or wholly away is frequently practised upon trees that either naturally grow too large for planting in the positions which they occupy or have fulfilled the purpose of affording shelter for a time, after which their presence could with advantage be dispensed with, and consequently they should be removed altogether. But it requires some courage to cut down trees when they have grown up near a dwelling, or already exist in over-close proximity to where a house is afterwards built, however unsuitable or out of place they may be for the place in which they stand; and when there is an absence of the knowledge requisite to judge correctly in the matter, mutilation, instead of removal, is generally resorted to. A similar course is often pursued where, in place of thinning out deciduous trees where their increased size demands more room, the whole are kept and mercilessly disfigured; than this nothing is more opposed to the admitted principle that a single well-developed tree judiciously placed is vastly preferable to any quantity of mutilated examples. Bearing upon this subject, it frequently happens that deciduous trees in shrubberies, which have attained considerable size, and which have occupied the position in which they stand long before the grounds were laid out, and where they are by far the most conspicuous and important objects, and consequently can ill be spared, somewhat suddenly lose all their upper branches, and begin to push out a quantity of small spray from the lower part of the trunk, a sure sign of languid vitality, although their age is not such as would directly lead to decay. In cases of this kind the complete removal of the heads, leaving them mere pollards, becomes a necessity, though no reasonable expenditure would have been grudged to have kept them in full vigour. I have recently seen several instances of this description, where pleasure-grounds more or less in extent had been made within a dozen years or so, and where the existent trees—mostly Oak and Elm—were of the very greatest importance in giving almost at once an apparent age and character to the places, that nothing in their absence could supply or compensate for. The cause of their loss was clearly visible, but too late to remedy the mischief: shrubs had been planted

thickly on the ground occupied by the roots of the old trees, and had grown freely without any attempt at the necessary thinning, so as to prevent their exhausting the soil of its fertilising elements, as also of moisture, which the roots of the shrubs from their position near the surface, do to the starvation and exhaustion of the much more important trees. These were direct evidence of the frequent mistakes made in unduly taxing the capabilities of the soil by over-cropping, with an absence of enriching elements, and which is just as injurious to the shrubs and trees, as it is with annual crops, though in the latter the effects are sooner seen. In the case of lopping, when it is carried to the extent that is frequently practised on hedgerow timber, it is at once destructive of the best features in the landscape—trees in their natural form. By a little observation, in passing over some of the principal lines of railway that traverse England; it is easily seen to what length this kind of work is carried out on some estates, where the trees often standing from six to a dozen in the place where one ought to be, either as regards the general appearance of the land, the production of good timber, or consistent with the growth of either corn or grass, but in place of their being confined to a sufficient number of healthy fully-developed examples, all are so denuded of branches that they consist of nothing but long, straight, attenuated stems and meagre heads, the whole not unlike a gigantic Birch broom with a long handle. As to the appearance of such, individually or collectively, it is needless to say anything. And, in respect to the formation of timber when the leaf surface is kept so much reduced, I have ascertained, by actual measurement with several kinds extending over a series of years, that the increase with trees so treated was not more than one half compared with examples of the same respective varieties grown under exactly like conditions, except that their branches were left intact, beyond a reasonable amount of pruning in the early stages of their growth.

In respect to the removal of large under branches from trees that have attained considerable size, where a sufficient cause exists for this being done, it requires much more judgment, and less of the indiscriminate serve-alike procedure than is often practised in the work. Some varieties of deciduous trees cannot bear large branches being cut away without injury to their general healthy condition nearly so well as others. The Beech, for instance, influenced to a greater or less extent by the nature of the soil and situation in which it is grown, is usually so much injured by the removal of branches that have attained any considerable thickness, that decay and ultimate death often ensue, the consequences generally being apparent by broad stripes of bark, and the outer wood to some depth immediately below, and extending for a considerable distance down the trunk, dying, from which decay ultimately extends so as to cause their premature destruction.

T. BAINES.

THE BEARBERRIES.

ALL the Bearberries are desirable and interesting shrubs, and well deserve that attention should be called to their merits as garden plants. Formerly the genus contained a good many more species than it does at present, the kinds removed being now classed under different genera. There are about a dozen species confined to north temperate regions, and of these the majority are natives of North America. Those hereafter mentioned do well in the open air in this country, and flourish best in peaty loam. Seeds offer the readiest means of propagation with most of the sorts, though all may be easily increased by means of layering. The two indigenous kinds make excellent rock plants, and, as such, deserve a place even in select rockeries.

The Black Bearberry (*Arctostaphylos alpina*), the badge of the Clan Ross, is rare as a native plant, being confined to dry, barren Scotch mountains from Perth and Forfar northwards, and ascending to elevations of nearly 3,000 ft. above sea level. It forms compact, woody patches, with stout, leafy, interlaced branches and scaly bark. The deciduous, spatulate leaves, which are wrinkled above, have ciliated margins, and are narrowed into a short stalk. They vary in length from $\frac{1}{2}$ in. to $1\frac{1}{2}$ in. and are coarsely toothed above the middle. The white blossoms are produced in twos or threes, and appear with the young leaves. The berry is black, and measures $\frac{1}{2}$ in. in diameter.

The Common Bearberry (*Arctostaphylos Uva-ursi*) is a handsome little shrub with trailing branches and quite entire, glossy, evergreen leaves. It prefers Alpine, heathy, and rocky places, often covering the ground with beds of considerable extent. Its geographical distribution is more southerly than that of the Alpine Bearberry, being found as far south as Cumberland and Yorkshire; it, however, ascends to even a greater elevation. The pretty urn-

shaped pink blossoms, followed by red fruits which afford an excellent food for the moor fowl, are produced in May and June in crowded racemes. In his "Flora Lapponica" (p. 130), Linnæus states that great quantities of the leaves and branches are gathered in the north of Sweden and sent to Stockholm, where they are bought by tanners for the same purpose as the Sumach (*Rhus Coriaria*); they are also used to dye wool. This plant was known to, and occasionally used by the ancient physicians, and, of late years, has been successfully employed in pulmonary complaints and also as an astringent tonic.

The Glaucous Bearberry (*Arctostaphylos glauca*) a native of Oregon and California, where it is known under the name of Manzanita, gets to be a good-sized shrub and bears abundantly large drupe-like fruits of a pleasant taste, which are much used as food by the Indians of that region.

The Woolly Bearberry (*Arctostaphylos tomentosa*), is a curious and beautiful hardy evergreen shrub from California and the Rocky Mountains, where it is also known as "Manzanita," indeed on the western coast there are several species, mostly shrubs or small trees, which have been much confused. It is a neat-habited bush, with roundish, glossy, leathery leaves and hairy branches; the foliage, when young, being also somewhat woolly. The wax-like flowers open about March, are pure white, and are borne in dense, drooping racemes. As a cool greenhouse or conservatory plant it is a decided acquisition. Its hardness, too, has been thoroughly tested at Kew, where a good specimen is standing perfectly uninjured by the late severe weather, although it has received no artificial shelter of any kind.

The Pointed-leaved Bearberry (*Arctostaphylos pungens*), from the same countries as the last-named, is a much branched, erect growing shrub, with leathery, quite entire, acute-pointed leaves, from 1 in. to 1½ in. long, downy when young and smooth when old. The terminal, drooping racemes are made up of eight or ten blossoms—white, tinged with rose.

Another kind widely different from all the foregoing, is one cultivated in the Edinburgh Botanic Gardens under the name of *A. californica*; this is a very vigorous, trailing, evergreen shrub, with spatulate, leathery, entire leaves; the flowers I have not seen. G.

CHEST FOR STEAMING TIMBER.

AN apparatus for steaming timber for bent work may be constructed as follows: A box of 2-in. plank is made of sufficient length, and

Chest for Steaming Timber.

about 1 ft. wide and deep. Three cross bars are fitted at the point shown in the engraving, and about 1 in. above the bottom. The timber rests upon these, so as to expose every part to the steam. The movable door is held in its place by bars passing through staples, as indicated in the engraving. The box rests upon trestles about 4 ft. high. A common cauldron or boiler may be used to make the steam. This may be hung upon a tripod, or set in a rough arch of stone. A wooden cover is fitted to the top and held down by clamps or weights. A pipe made of wood or metal connects the boiler with the steam box.—"American Agriculturist."

[A somewhat similar contrivance to that here described is used in this country for steaming timber for wheelwrights.]

The Hardest Evergreen Magnolia.—It is in such seasons as this that the ferrugineous variety of *Magnolia grandiflora* shows its superiority, and we have little doubt it will generally be found that it is unburt, or comparatively so, while the favorite *Emouth* variety, is killed down to the ground, if not indeed killed outright. It usually happens under such circumstances as these that *M. grandiflora ferruginea* stands quite uninjured, and therefore we have come to regard it as the hardest, as it is the freest-blooming, and in every way the best variety of this grand American evergreen.—"Gardeners' Chronicle."

WOODLAND WORK FOR FEBRUARY.

UP to the present time there appears but little chance of fetching up arrears of planting, and, whenever the weather breaks, the most strenuous efforts must be made to push forward such work with all possible speed. In many places evergreens removed late are completely cut off, and, when the spring arrives, we may expect to find much mischief done in late made plantations of all kinds. But wherever early provision for planting was made by trenching and holing, the benefits of the frost will be felt in the complete amelioration of the soil, so that good work may be done in the spring. The frosts have greatly impeded the cutting of underwood, and, owing to the brittleness of the wood, much of the work done is of an unsatisfactory kind, and the stools should be dressed with the axe and adze as soon as the frost is out of them. The weather has been greatly in favour of the removal of all thinnings of timber, and of the produce of early cut coppices. All timber, except Oak, should be felled by the end of the month. Wherever there is a demand for the bark of the Birch, Larch, Willow, Spanish Chestnut, &c., these may be cut down later in the season.

The drier portions of the woodlands should be selected for the earliest planting with Larch and Spanish Chestnut, afterwards following up with Sycamore, Beech, Ash, and Elm, and finishing upon the more retentive soils with the Oak, Birch, Willow, and Poplar. Wherever Brambles and rank undergrowth of any kind abound, strong plants should be used for filling up, as smaller ones would soon be smothered. But, in forming entirely new plantations, three-years-old Sycamore, Maple, Spanish Chestnut, Pinaster, Larch, Birch, Ash, and Alder, will be sufficiently strong; the Oak, Spruce, Beech, and Walnut should be used at the age of four years; and the Holly, Silver Fir, and some others, at that of five years.

The formation of Hawthorn hedges should be completed as soon as the weather will permit, as this plant comes early into leaf. In all soils, except very retentive ones (for which the Hawthorn is not well suited), the plants are better placed upon the level of the adjacent land. The raised mound, with its deep side ditches completely cuts off the roots from the free range which they ought to have in the soil beyond; hence the scrubby appearance which hedges so placed too often present. In such situations their roots also receive a severe pruning whenever the ditches are scoured or shovelled out. In very wet situations tolerably good fences may be made with the semi-aquatic plants—the Alder, Willow, and Black Poplar. When cropped close, the Alder and Poplar feather low, and the forked growth of the former, combined with the bitter taste of its leaves, prevents its being cropped, and renders it well-nigh impervious to cattle. The Willows may be thickly planted in such situations, and their branches interlaced, so that no stock will find its way through fences formed of these.

Layering, both in the woodlands and the nursery, may now be continued, the layered part being fixed firmly in the soil by means of a wooden peg, and afterwards covered to a depth of about 4 in. with good soil. The end of the shoot should be left in an erect position. Such trees as are intended to attain considerable size in the nursery should, at their final transplanting, have sufficient space to enable them to develop robust stems and well balanced heads, as upon these two points much of their future success will depend. Such as are afterwards intended to stand singly or in small groups in situations of exposure should also remain for some time in the most open of the nursery quarters.

Late in February or early in March Willows may be cut both for the use of the cooper and the basket maker. Those for the former may be cut tolerably close to the ground and near the swelling at the base of the shoot, for as very few shoots from the stool are required where large growths have to be produced, the ascending sap has sufficient outlets from this protuberance; but, in cutting the basket maker's Willows, the section should not be within two or three buds of the base, and made in a slanting direction. The cut osiers are prepared for peeling by standing on end in bundles in a few inches of stagnant water, and they are ready for the operation some time in May.

Cuttings of various kinds may still be inserted in the nursery beds, though a better start will be obtained by those put in at the end of the autumn. Elder branches taken from the last year's shoots may have one pair of their buds under the soil and one above. The cuttings of Poplar and Willow require to be planted tolerably deep in the soil, and they should be taken from the last year's shoots; but where it is intended to plant a permanent Osier bed, stronger cuttings, of the length of 18 in. and upwards, taken from two years' old wood, are preferable. But, as this kind of planting consumes so much material, the strongest of the one year's shoots, and about 1 ft. in length, are often substituted.

As soon as the larger deciduous kinds have been got out, the removal of two years' seedlings will require attention. This may be

followed up by the transplanting of seedlings; but these and the Larch are generally better left until early in March. For filling up all vacant spaces in the nursery which have been under green crops during the past summer, and which are not required for seed beds, stock should now be ordered in, or at any rate selected in readiness for removal when required. Chestnuts and Acorns may still be put in, giving them a lighter covering than in the autumn. Choose plump, well-ripened seeds, the produce of vigorous trees in the prime of life, as these produce the strongest plants. In fine dry weather, towards the end of the month, sow Sycamore, Maple, Ash, Beech, and Elm seeds. Also dig and lay up roughly such quarters as are intended to make seed beds for the Fir and Pine seeds in March.

Whenever the weather will permit, keep the hoe going among the nursery lines. Also keep a watch for mice and other destructive rodents, which soon do a great amount of mischief among the seed-beds. Digging between the nursery rows, provided the operation be performed with care, greatly assists the formation of fibrous roots and renders the plants better fitted for future removal. Before the March winds come, it will be well to stake and tie all large transplants likely to require it, and to fix the soil well around such as have already become loosened.

A. J. BURROWS.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Beech Trees and Underwood.—Allow me to give the following particulars in reference to this subject, as I am of opinion that there is no more difficulty (if so much) in growing underwood under Beech trees than there would be under Elm or Oak, provided the Beech trees were not planted very closely together, or the branches allowed to hang so low down as to shut out sunshine and air. We have here, in the park, many Beech trees, also Elm, Chestnut, Limes, Oaks, Horse Chestnut, and various others, but I can see no difference in the Grass under any of them, it being as luxuriant and plentiful under one kind of tree as under another, the branches being from 5 ft. to 6 ft. from the ground. There is also, running through part of the shrubbery, a kind of avenue of large Beeches, planted at long distances from each other, but most of them meet at the top, forming a thick shade when in leaf; under these the ground is very full of roots, as it has not been dug for ten or twelve years, the space under the trees being planted with common Laurels, Portugal Laurels, Laurustinus, Box, Irish Yews, common Yews, green Hollies, Aucubas, variegated Hollies, and a few others. Of these some are making fine plants, especially where they have head room, and others grow so fast that we have to prune hard to keep them within limits. Not a mile distant there is a very large group of Beech trees planted thickly, with an occasional Larch or Scotch Fir; these are all drawn up together very high, with scarcely any lower branches upon them, but underneath there is scarcely any vegetation, except an occasional Bramble or tuft of Grass. Even common weeds make no attempt to cover the bare surface, but here the ground is very stony and poor.—W. DIVERS, Maidstone.

—With regard to the Rhododendrons in the Beech wood at Alderley, seeing the matter doubted, I beg to confirm Mr. Hossack's statement. It is over twelve years since I lived at Alderley Park, and they were then all that Mr. Hossack describes them at a later date.—J. SLATTERY, Berrymeade Priory, Acton.

Pinus Laricio.—Nothing connected with tree planting for purposes of timber growing goes farther to show how slow people in some cases are to adopt anything new, or comparatively so, than this Pinus, the excellence of the timber of which has long been well known. This would be more easily accounted for if the Larch had continued healthy and vigorous, but with the way in which it is now often affected by heart-rot when the trees are approaching an age to be of value for purposes where size is required, and the still greater extent to which it is attacked by disease in the earlier stages of its growth, to continue planting it in the numbers that still is practised seems like hoping against hope. The quality of the timber of *P. Laricio* is sufficiently known to establish its character, and the only reason that appears intelligible why it is not more generally adopted by planters is the higher price, consequent upon the young plants in their first stages of growth, being somewhat delicate, but after that stage has been passed, it grows away with a vigour which leaves nothing to be desired. The matter of cost might, in a great measure, be met by only planting it in such quantities as may be required for permanency, using cheaper kinds for nurses and still later thinning out. In addition to the value of its wood, the progress which it makes in another matter in its favour, being quite as rapid in growth as is consistent with strength and durability of timber.—T. BAINES.

ROSES.

ROSE GROWING IN FRANCE.

PRUNING ROSE TREES.—Pruning is an operation which has for its object the formation of the head of the Rose tree into such a shape as will best suit its nature, as well as develop young shoots that will yield an abundance of bloom. The method of pruning to be adopted depends on the natural habit of the particular variety with which we have to deal. Vigorous pruning in the case of a free-growing variety gives rise to an exaggerated development of suckers at the roots and of watery shoots on the branches, growths which exhaust the energies of the trees without producing any flowers. On the other hand, a slight pruning in the case of a weak variety will promote the production of more Roses than the sap will nourish, the flowers being small and badly shaped. If we could divide Rose trees into distinct classes, according to their mode of growth, it would be easy to point out the particular method of pruning which is best adapted to each sort, but it is very difficult to make this classification in an absolute manner, sides which the luxuriance of plants of the same variety differs considerably, according to the fertility of the soil and the mode of culture. It follows, therefore, that in practice rules that are too absolute may become embarrassing, for the practical cultivator must not only take into account the luxuriance of the growth of the particular variety, but of the particular individual plant also. It will be therefore as well to confine ourselves to a few general principles as applied to the natural divisions of Roses, without specifying varieties. Free-blooming and slow-growing Roses should be pruned down to two or three eyes, or say to within $1\frac{1}{2}$ in. to $1\frac{3}{4}$ in. of the stem; Roses with varying habits of growth to four or five eyes, or from $3\frac{1}{2}$ in. to 4 in.; Roses of vigorous growth to six or seven eyes, or 6 in. to 7 in.; climbing Roses bearing but few flowers to 8 in. or 12 in.

PRACTICAL DETAILS OF PRUNING.—Going up close to a Rose tree we examine it rapidly, and determine, from two or three glances, which are the branches that are to be preserved. Trim the head by cutting down all watery shoots, weak or badly-placed branches; cut away the stumps of branches pruned off the year before, and any dead wood that may be left; in fact, clear away everything that interferes with the growth or beauty of the tree. When nothing remains on the tree but the branches to be preserved (fig. 25), that is to say, from six to ten, according to the vigour of the subject, we must commence pruning them, in accordance with the principles there indicated. The cuts should be made in a slanting direction opposite an eye and at $\frac{1}{2}$ in. above it. The eye chosen should, if possible, face outwards. As a guide to amateurs who are obliged to depend on themselves, we shall say a few words on the mode of pruning the best known varieties. In the case of Tea Roses, Bourbons, and Noisettes, which are very prolific in flowers when grafted on the Brier, we must prune vigorously, leaving a space of 3 in. or 4 in. between the branches. With Bengal, Tea, Noisette, and Bourbon Roses growing on their own roots we must only leave five or six choice shoots at the base of the flowering branches of the preceding year. Many-flowered and evergreen Roses which are generally used for covering walls and posts, we must prune back vigorously during the first year, in order to obtain two or three shoots which will grow the length of some 9 ft. or 10 ft., taking care to train them in the right direction. The second year we must shorten them back to within about 3 ft. of their bases, which will cause them to branch out all round. With the third we must begin to cut down the terminal shoots for from 2 ft. to about 2 ft. 8 in., and the sides shoots must be pruned back to three eyes. Climbing Noisette Desprez, Chromatelle, Lamarque, Solfaterre, and other Roses of the same class must be cut back to about 6 in. or 1 ft., according to the thickness of the branches, so as to obtain lateral shoots, which will each bear a bunch of flowers at the end. The longest branches must be cut back as the tree gets older, and the young shoots which refuse to bloom must be bent, in order to force them into flower. Banksian, Persian Yellow, and some other Roses bloom on the wood of the previous year; therefore we must

be careful not to interfere with these branches, or, indeed, any others which are likely to bear flowers.

THE SEASON FOR PRUNING.—The time for pruning necessarily varies with the weather and climate. About Paris, for instance, we may prune Hybrid Provence and Moss Roses before winter sets in, but it is much more prudent to wait until March. We begin with the hardest varieties, keeping China and Noisette Roses, and those growing on free stocks, to the last. All these delicate varieties, which should be kept covered up during the winter, should be pruned as soon as the coverings are taken off.

GROWING ROSES IN GARDENS.—The same constant attention must be given to Roses, no matter for what purpose they may be grown, whether for the purposes of the amateur or the pro-

Fig. 25.—Pruning.

fessional horticulturist. The following is a short account of what is required to be done in order to grow Roses with success.

Manure.—Every two years, when the ground is dug up, either in spring or autumn, the soil must be well manured. Cow manure should be used for light, sandy, or calcareous soils, and old night soil, the bottom of manure heaps, and half-rotted stable manure, for heavy and clayey lands.

Suckers and Watery Shoots.—Every time that the ground is dug over, the base of the Rose trees should be carefully examined. The suckers should be cut off below the ground with the pruning knife, and not with the spade, as is often done. When the latter tool is used a stump is always left behind, which will sprout more vigorously than ever. The

branches must also be looked after, and all shoots which have made their appearance below the graft, and which would otherwise soon develop into watery shoots, must be removed.

Cockchafer Grubs.—At the time of digging up the beds a sharp out-look must be kept for these and all other destructive larvæ.

Covering with Manure.—A layer of stable manure, from 2 in. to 3 in. thick, spread round the base of the Rose trees, greatly favours their growth. The layer of manure keeps the soil slightly moist, and the earth does not crack, besides which the roots are not exposed to the heat of the sun. The water with which they are watered, and the rain, is retained upon the surface, and gently penetrates the soil. Besides this, the litter, as it decomposes, provides a supply of manure at the very time when the trees are most abundantly absorbing nourishment from the earth. The stable litter for this purpose should be half rotten and mixed with night soil, the bottoms of warm heaps, rotten leaves, and stable litter, taking care to use those substances which are the richest fertilisers for the heaviest lands. The manure should be applied before the hot weather sets in, and after the soil has lost the moisture left in it by the spring rains. This ordinarily takes place about the end of May, or somewhat before or after, according to the climate and nature of the soil. Before applying the manure we must give the ground a good hoeing, and the beds and borders should be well weeded. These operations should, if possible, be performed immediately after a slight shower of rain.

REPLACING DEAD SUBJECTS.—LEAF-PRUNING.—Both the horticulturist and the amateur have an equal interest in replacing dead Rose trees as soon as possible, for which purpose we are often obliged to transplant subjects before the proper time, in fact, while the sap is in the trees. In such cases great care must be taken to strip the tree to be transplanted of the whole of its leaves, and even of its unripe shoots. Without this precaution the branches would become wrinkled and the leaves would continue to waste the sap by evaporation, the roots being unable to supply its place by absorption. If the Rose has to be moved and cannot be transplanted to its proper place at once, it must be laid in by the heels and watered once or twice a week in order to restore the wrinkled rind to its proper condition. The operation of leaf-pruning should be performed not only when an isolated Rose tree is transplanted, but also in the autumn, when professional horticulturists, in order to satisfy the wishes of their customers, are obliged to take Roses out of their beds before the sap has ceased to flow. Leaf-pruning thus becomes an important operation, which not only saves the plant and insures its taking root, but allows it to be transplanted under favourable circumstances, because, as the trees are placed in the ground at the beginning of autumn, they have time to grow a little and to become firmly established before cold weather sets in.

PACKING ROSE TREES.—When the distance the trees are to travel is small we need do nothing more than moisten the roots and grafts, wrapping the whole round with a thick layer of straw and tying with Willow twigs. If, however, the distance be great, we double the packing of straw and cover it with a piece of oilcloth secured with twine. If the Rose trees are to travel by sea we must first dip their roots in a mixture made of equal parts of light earth and cow manure, mixed with sufficient water to form a thin cream. They are then allowed to dry and packed in boxes, being separated from each other by layers of dry Moss. If we have to deal with Roses in pots they must be unpotted and the ball surrounded with a layer of Moss, kept in its place by string; they are then packed in wooden boxes or osier baskets, according to the distance which they have to travel, care being taken to separate them from each other by layers of dry Moss.

SUMMER PRUNING.—As soon as the Rose trees have ceased to bear flowers we cut off the branches which have produced them, taking care to preserve the neighbouring buds. In those varieties which have only one flower at the end of each branch we cut it down to within a couple of eyes of the flower stalk; we also cut down the watery shoots which project beyond the branches to one-half their length in order to force them to ramify and bear flowers. This operation should be performed

gradually and continuously, and should begin with the fading of the first Rose until the tree has ceased to flower. When this has taken place a general pruning is given to the trees by cutting back all the healthy shoots which have borne flowers to a well-formed eye, the first below the flower if possible. All weak branches and shoots which have not borne flowers must be cut down, as they would only cause a loss of sap. The pruned shoots will soon have the full benefit of the sap, and will yield another crop of flowers not less beautiful or abundant than the first. This general pruning is a very important operation for varieties whose branches spread far and wide, such as Tea-scented, Noisette and Hybrid Roses.

TRAINING STICKS FOR ROSES.—The stems of the Rose trees are kept in their places by training sticks, which are especially necessary where the trees are much exposed to the wind. It is not only the breaking of the stems that we must guard against, but we must take care that no infiltration of water takes place at the root of the trees through the gap caused between the lower part of the stem and the soil, through the stems swaying about in the wind. Such crevices only form so many funnels for collecting the rain and conveying it to the roots in too great quantities. The training sticks may be replaced by iron rods or tubes of 1 in. in diameter, covered with three coats of common green paint. Slate supports have lately been introduced by the owners of the Angers slate quarries; they are excellent for the purpose but are rather heavy and liable to break. The supports most generally in use are made of wood; they are easily procured, and may be made to last practically for ever by soaking them in a solution of blue stone (sulphate of copper) or by giving them a coat of tar. To prepare training sticks in the first way, we dissolve 2 lbs. of ordinary blue stone—blue vitriol, or sulphate of copper as it is often called—in 5 gallons of hot water. When dissolved, the solution should be poured into a tub of sufficient depth to take the supports, which should be entirely immersed in an upright position for a week or ten days, at the end of which time they should be placed the reverse way for the same period, after which they may be taken out and dried, and used at once or stored away. Sulphate of copper may be bought at any oilman's or chemist's in small quantities, at 6d. or ed. per lb. If a second batch is to be prepared, more solution, of the strength indicated above, must be added to the old; the solution does not become weaker by use, but is diminished by the absorptive powers of the sticks. It is almost unnecessary to add that sulphate of copper is a violent poison. The tar is applied with a hand paint brush, either hot or cold, according to circumstances. The tar generally takes a long time to dry, and there is always a danger of soiling one's fingers and clothes with it until it does, and even after it is dry to all appearance, a day's sun will be sufficient to melt it again. Paraffin oil applied with a brush is also used for this purpose, but it has a penetrating odour that to most persons is extremely disagreeable. Training sticks prepared according to either of the processes described above, have the advantage of protecting the Rose trees from the attacks of certain insects. With the same view it is a good plan to soak all tying material in the sulphate of copper solution. The position of the training stick is a matter of indifference, it is, however, generally placed upright and as close to the stem of the Rose tree as possible, so as to be out of sight. The stem of the Rose tree is kept in its place by two or three pieces of Willow, or other tying material, care being taken to interpose a thick pad of Moss between the stem and the support. J. LACHAUME.

level with the walk in question, from which their full beauty when in flower can be seen. The plants, of which there are many hundreds, are not planted too thickly; they embrace all the best kinds known in cultivation, and when in full bloom the effect from the terrace walk just alluded to, as well as from the windows of the mansion must be fine indeed.—S.

NOTES FROM KEW.

Stove Plants.—Amongst these we notice a charming *Amaryllidaceous* bulbous plant named *Ureocalia pendula* (syn. *Ureocalia aurea*), introduced a few years ago by Messrs. Veitch from the Andes, where it was discovered growing in woods at a considerable elevation. It forms a globose bulb, which throws up a stout flower stalk, terminated by an umbel of from six to twelve blossoms borne on slender, drooping pedicels. In form they resemble an inverted pitcher about 2 in. long, and in colour they are of a rich yellow on the outside, gradually merging into the deep green at the mouth, the divisions of which are bordered with white. One detracting point is that the flowers are unaccompanied by leaves, at least in the Kew specimen, but, even as it is, it requires only to be seen to be appreciated. The majority of the showiest *Bromeliads* exhibit in their floral beauty a strange contrast of colour, and, notably, the superb *Billbergia paleacea* and *Liboniana*, the former with the flowering axis clothed with deep pink, pointed bracts, accompanied by yellowish-green narrow blossoms; the latter with the flowers of various shades of purple, and the flower leaves rich carmine. The variety, called *picta*, of the old bulbous *Tillandsia* (*T. bulbosa*) is superior to the type, on account of the upper leaves changing to a bright flesh colour; the blossoms are also of the same colour.

Orchids.—The most conspicuous amongst these include the rare little Brazilian *Trichocentrum tigrinum*, a small specimen attached to a block and bearing a solitary flower, which is about 1½ in. across, with a rather large bilobed lip, two-thirds white, with a magenta blotch on each of the golden crests; the other segments are greenish banded with chocolate, and exhale a delightful aromatic fragrance. It is a bulbless kind, with thick, pointed leaves marked with dark spots. The various kinds of *Phalaenopsis* are certainly amongst the loveliest of all *Orchidaceous* plants, and here we find flowering examples of several of them, amongst which may be named *P. amabilis*, with its delicate white blossoms; and *P. Schilleriana*, with deep rose-coloured flowers, in addition to the handsomely marbled spreading foliage; whilst a smaller-flowered kind, *P. rosea* (syn. *P. equestris*) has pale pink blossoms with a darker lip copiously spotted with orange, and the whole flower strikingly resembling a bird in the act of alighting. All the above are natives of Manilla. Two superb varieties of the spotted *Saccolabium* (*S. guttatum*) are *violaceum* and *gigantum*; the former with dense, pendulous racemes of waxy white blossoms profusely spotted with purple; the latter with larger flowers, broader segments of thicker texture, and fewer spots; both yield a delicious perfume. *Oncidium serratum* is one of the finest of the small-lipped section of the genus; the flowers are nearly 3 in. long, with a roundish upper segment of a rich chocolate colour, the two lower being long and narrow and of the same colour, the other pair united and one half of a pale yellow; the lip is very inconspicuous. It is a native of Peru, and deserves a place in every collection. A fine example of that little gem *Sophranitis grandiflora* is still producing its brilliant scarlet blossoms.

Greenhouse Plants.—One of the most pleasing shrubs which we have seen for some time, though by no means novel, is the *Glandular-leaved Anopterus* (*A. glandulosa*). In its native habitat, which is Tasmania, it forms a bush from 2 ft. to 3 ft. high with leaves from 4 in. to 6 in. long, leathery in texture, and coarsely toothed in the upper half. The blossoms are borne in short dense racemes, terminating the branches in clusters; they are ½ in. across, pure white, with a faint dash of pink on the outside, and they continue for a long period in good condition. The membranous flower leaves are covered with glands; hence its name. Probably, in some of the most favoured localities in the southern counties, it will thrive in the open air with the protection of a wall. The Lance-leaved *Leucopogon* (*L. lanceolatus*) is another neat shrub from the adjoining country of New South Wales, found abundantly in the vicinity of the Blue Mountains, where it forms large shrubs many feet in height. The plant at Kew is literally covered with blossoms, which are produced in clusters at the tips of every branch, and intermingled with the narrow light green foliage. The individual flower is very small, pure white, and the petals beautifully fringed. Being admirably suited for cutting, it should be found in every collection; and the same may be said of that lovely old favourite the Japanese *Iris* (*I. japonica*—syns., *I. fimbrata* and *chinesis*), which is a remarkably free-flowering kind when under greenhouse culture, forming handsome specimens with graceful

Situations for Rose Gardens.—The Rose garden at The Poles, Ware, is one which shows to how much better advantage Roses may be seen by planting them in suitable situations than by placing them, as is frequently done, in long lines by the side of walks or in isolated clumps. This applies chiefly to standards when planted on a level with walks or on raised borders, for when so situated the naked stems and the undersides of the leaves and blooms are chiefly visible, and the true beauty of the Roses is, to a great extent, lost. At The Poles, the Rose garden occupies a position some 3 ft. or 4 ft. below a long terrace walk supported by a wall clad with Ten Roses and Clematises. The tops of standard Rose trees thus situated are nearly

arching foliage, and throwing up many stems, branched at the apices, bearing blossoms 2½ in. across, with the segments—not, as in the majority of *Iris*es, the outer erect and the inner drooping, on the contrary, they are all on the same plane, thereby enhancing their attractiveness. The colour is a delicate mauve, marked with spots of a darker hue; the three larger segments have rich yellow blotches, and the margins of them are delicately fringed. The variety magnifica of the well-known, long-leaved *Acacia* (*A. longifolia*) is a decided improvement on the species. The bright yellow slender cones of blossoms, formed in the axils of the deep green leaves, render it very desirable for associating with the larger subjects of the conservatory. *Lemoine* *Monochætum* (*M. Lemoineanum*), a very profuse flowering kind, is particularly noteworthy. It grows nearly 3 ft. high, and has small foliage, which is almost hidden by the numerous deep rose blossoms, 1 in. across, with a tuft of singular horn-like stamens in the centre. W.

NOTES OF THE WEEK.

Hæmanthus albo-maculatus.—This is flowering just now in quantity in the Pine-apple Nursery. It is an excellent plant for both winter and summer decoration, as under good treatment it blossoms twice yearly. Its leaves, which are long and broad, are of a bright green colour, effectively spotted with white, whilst its flowers are pure white, and the stamens golden.

Cyclamens at Holloway.—Nowhere have we seen the improvement which has been effected in the varieties of the *Cyclamen* better exhibited than in the Victoria Nurseries, Holloway. At present there are large numbers of plants there in full beauty, the flowers of which are large, and in brilliancy of colour are unsurpassed by any with which we have hitherto met.

Choisya ternata in the Greenhouse.—In addition to this being a desirable plant for outdoor culture on walls, &c., it is also worth attention as a pot plant in the greenhouse, where it flowers freely in February and March. Plants of it are now coming into blossom in one of the houses in the Pine-apple Nursery.

Gilbert's Double Primulas.—Our readers will doubtless be glad to know that the new kinds of double Chinese *Primulas* shown on several occasions by Mr. Gilbert, of Barchley, at South Kensington, and to most of which first-class certificates have been awarded, are to be distributed in Aug. next by Messrs. Osborn, of Fulham. Amongst the kinds to be distributed are *White Lady*, white, tinged with violet; *Mrs. Barron*, white, suffused with purple; *Princess*, white, striped and spotted with crimson; *Lord Beaconsfield*, red; and others equally attractive.

Hardiness of *Todea superba*.—Plants of this filmy Fern growing in an unheated house for some time past in the Pine-apple Nursery, have withstood the past severe weather without any protection whatever except that afforded by the glass. They still remain in robust health, notwithstanding that 14° of frost have been registered in the house which they occupy. This at once does away with the notion that filmy Ferns require coddling in glass cases or under bell glasses, or that in order to grow them successfully heated structures must be purposely provided for them.

Orchids at Holloway.—Even during this unfavourable weather there is a good display of Orchids in Mr. Williams' nursery at Holloway. Amongst others we noticed large specimens of the well-known *Cologne cristata*, furnished with multitudes of snowy-white blossoms, *Calanthes*, the brilliant *Sophronitis coccinea* and *grandiflora*, and the rare and beautiful *S. violacea*. A specimen of *Phalæopsis Schilleriana*, producing two branching spikes 3 ft. or 4 ft. long, is furnished with nearly 200 flower buds, which will soon be expanded, and *P. amabilis*, in the same house, is in full bloom. There is also a good display of the ivory-white flowers of *Angræcum sesquipedale*. Being tastefully arranged among Ferns, Grasses, and other fine foliaged plants, the flowers of the Orchids are set off to the best advantage, rendering the houses in which they are kept most attractive.

Prizes for Vegetables.—At Messrs. Webb & Sons' root show, to be held at Curzon Hall, Birmingham, in November next, nearly £500 are offered in prizes for vegetables and Potatoes as follow:—The best collection of eight distinct varieties of vegetables, four specimens of each, £5, £3, £2, £1; Webb's improved Banbury Onion, twelve specimens, £1, 10s., 6s.; Parsnip, twelve best roots, 10s., 7s. 6d., 5s.; long Red Carrot, twelve roots, 10s., 7s. 6d., 5s.; short Red Carrot, twelve roots, 10s., 7s. 6d., 5s.; best collection of twelve varieties of Potatoes, twelve tubers of each, £5, £3, £2, £1; Webb's im-

proved Schoolmaster Potato, twenty-four tubers, £2, £1, 10s., 5s.; Webb's improved Magnum Bonum Potato, twenty-four tubers, £2, £1, 10s., 5s.

Prizes for Early Peas.—With reference to Messrs. Suttons' prizes for early Peas, we are requested to state that in consequence of the continued severe weather impeding gardening operations, Messrs. Sutton have withdrawn the restriction as to the early Peas to be competed for at the Royal Horticultural Society's summer show being grown in the open ground, and that intending competitors may grow their specimens in any way best calculated to produce well-filled pods.

Crotons Prince of Wales and Williams.—Among the many old and new *Crotons* to be found in the Holloway Nurseries none are at the present time equal in appearance to those just named. Their leaves are of the richest shades of colour, and, unlike *Crotons* generally, are equally bright now as at other seasons.

Asparagus decumbens.—This most graceful *Asparagus*, sent to us a short time ago by Mr. Vertegans, of Birmingham, in fruit, has recently been sent to us in flower by Messrs. Rodger, McClelland & Co., of Newry. Its flowers are deliciously scented.

Christmas Roses.—The common Christmas Rose is largely grown in 6-in. and 8-in. pots in Messrs. Osborn's nurseries at Fulham. Its flowers are in great request for bouquet making, and plants of it flowered as we here find them, are very handsome in the conservatory, far more so, indeed, than when grown in larger-sized pots.

Pitcher Plants, Crotons, and Palms.—Few of the houses in the Victoria Nurseries are more effective than one which is filled with vigorous young *Crotons*, and graceful plants of *Coccoloba Weddelliana*, over which are hung *Nepenthes* furnished with numerous healthy pitchers. The same house also contains some fine plants of *Earracenia purpurea*.

Andromeda calyculata.—Though hardy, this plant is very effective in the conservatory in winter. It forces readily, and bears a profusion of small, white, waxy, Lily of the Valley-like blossoms, which are useful in a cut state. Its greatest drawback is its brownish foliage, against which its flowers cannot be seen to such advantage as they would be against green leaves. We find it well in flower at the present time in Messrs. Henderson's nursery.

The Arcades at South Kensington.—It is reported that the commissioners of the exhibition of 1881 propose to convert the arcades in the Royal Horticultural Gardens into a permanent market for the sale of fruit, flowers, and choice vegetables. These arcades have glass frontages to the gardens, and are paved and heated. They will be apportioned according as may seem necessary and they will be open to the public free. Should this scheme be carried into effect, it may prove of advantage to the public and by no means detrimental to the Royal Horticultural Society.

National Rose Society.—A meeting of the general committee of this Society was held at the rooms of the Horticultural Club on Wednesday last, Mr. R. G. N. Baker, of Heavitree, Exeter, in the chair. There was a full attendance, and various parts of the country were represented. The schedules for the Crystal Palace and Manchester exhibitions were finally arranged, some slight alterations having been made. Messrs. T. Francis Rivers, J. Barnaby Atkins, and Arthur G. Soames were elected members of the executive committee; drawings for a die for the Society's medal were submitted and approved; and it was considered that the best way of increasing the number of members would be to obtain the services of some more local secretaries. Birmingham was suggested as a desirable and probable place of meeting for the provincial show in 1880.

"The California Horticulturist."—Our correspondent, Mr. Charles H. Shinn, became the editor of "The California Horticulturist" on Jan. 1 of this year. Mr. Shinn is well acquainted with the needs of Horticulture on the Pacific coast. In no country that we know of has horticulture made such rapid progress as it has done there; there are now many beautiful gardens in that country, while, about the time of the first London exhibition, there was not even one.

New Flowers and Vegetables.—Messrs. Carter & Co., High Holborn, have issued in a convenient form an illustrated catalogue of new and choice vegetable and flower seeds for the present year. Amongst them are new Peas, Cucumbers, and Melons, the beautiful double *Eschscholtzia*, choice strains of *Balsams*, *Calceolarias*, *Primulas*, and similar plants.

Lachenalia quadricolor.—This, though seldom seen, is one of the prettiest of the *Lachenalias*. Other varieties are often thus named, but the true kind appears to be scarce. It is now flowering in some of the nurseries about London. Its blossoms are reddish-orange, tipped with bright purple.

GARDENING FOR THE WEEK.

Stoves.

Preparation for Potting.—It is now time to see about potting some of the earliest started stove plants, and soil should at once be prepared. In all cases not only ought it to be in a medium condition as to moisture—that is, neither too weak nor too dry—but it is a matter of great importance that previous to use it should be so warmed as to bring it up to something like the temperature of the house in which the plants are growing, for to place a body of cold material, in the way in which it is frequently done, in contact with the roots, has a most injurious and stagnating influence on them. Where there has happened to be a flue running for some length in a horizontal direction from the boilers, I have used this whereon to warm a good body of peat, loam, and sand ready for use, and if the material be too wet, such a place is very suitable for drying it; but in thus preparing soil, great care should be taken that it is not overdried, as experience points to the fact, that when soil is placed in close proximity to a heated surface whereby it becomes too dry, the essential elements of fertility are dissipated. To look thus narrowly at what might be termed by many trivial matters, may seem unnecessary, yet it is attention to small details of this kind that makes the difference between complete or partial success. Where no convenient place of the above description exists for warming the soil, it may be put into boxes and placed over the hot-water pipes. If a calculation be now made as to something like the quantity of peat and loam that will be needed during the next month or two in the repotting, it can with advantage be at once so far prepared by breaking it up with the hand, not sifting it, and reducing it to different sizes, in proportion to the large or smaller description of plants that require shifting.

Alcacias.—Those of the *A. metallica*, Veitohi and Lowi section do much the best in very light material, using nothing but fibre, with the earthy portion of the peat removed, mixed with about two-fifths of chopped sphagnum, to say, a sixth part of rotten, dry, flaky manure, such as may have been used for summer mulching. A vine border or wherever it would be similarly exposed to like drying influences of sun and air; to this should be added a good proportion of sand and a liberal sprinkling of pot shreds and charcoal. In a mixture of this sort these plants will grow and increase to an extent not possible in ordinary potting material. They are much better wholly, or almost wholly, shaken out so as to get the old soil entirely away from them. It is best, also, in repotting to take the small crowns and offsets away, keeping the stronger growths by themselves and treating the weaker ones in like manner. They are very shallow rooters, consequently, the pots should be half filled with drainage, similar in this respect to Orchids. *A. Jenningsi* is one of the most beautiful of the small-leaved kinds; it will do well in material such as the above, putting either a number of the crowns together in shallow pots or pans, or in the shape of small plants for placing about amongst the other occupants of the stove. *A. macrohiza variegata*, although from the quickness with which it may be increased, is not thought so much of as some of the scarcer kinds of recent introduction, it is one of the handsomest and most effective plants which we possess. In the matter of soil it requires to be quite differently treated from the others; it is hardly possible to make the material in which it grows too rich; one-half yellow loam to an equal proportion of thoroughly rotten, dry manure, and one-sixth sand, will in every way suit it. In selecting young offsets of this *Alcacia*, those should be chosen that have somewhere near an equal proportion of green and white in their leaves; suckers with too great a preponderance of white are deficient in vitality to grow freely, whilst, on the other hand, those that contain too much green in their early stages seldom attain colour enough to make them attractive.

Caladiums.—It is desirable to start these at two different times, by which means a portion may be had late in the autumn with handsome, healthy foliage, at a time when the earliest grown plants have lost their colour. In potting, it is well to consider whether large or small examples will be the most useful, for in no case is it advisable to over-crowd the pots, as, where this occurs, the leaves will not acquire their wonted size. They will succeed in either loam or peat, but I have found the foliage to possess more substance when grown in loam than in peat.

Poinsettias.—Plants of these that have done flowering should receive no more water at present; they should be stowed away in any place where there is an intermediate temperature for some time, until they require to be started again into growth.

Ardisias are most useful when comparatively small and fully furnished with leaves to the base. Any that are getting too large and that have lost their lower foliage should now be headed down and

put into a brisk heat, where they will at once make several shoots. When these have attained a few inches in length all but one can be taken off with a heel and struck. They will make good small plants much quicker than seedlings. The stools may then be partially shaken out, repotted, and grown on with a single stem, a way in which they look much the best.

Miscellaneous Plants.—Plants of the handsome *Apelandra cristata* that flowered last autumn should now be kept in the stove to encourage their making young growth for purposes of propagation. Of *Eranthemum pulchellum*, *Plumbago rosea*, *Scutellaria Mociniana*, *Sericophoria Ghiesbreghtiana*, and *Thyracanthus rutilans*, a sufficient number of such as have done blooming should be cut back and placed in the stove, where they will be induced to make growth for cuttings. They should have plenty of light, so that the young shoots may be short and stocky, as upon that very much depends their making stout, healthy plants for blooming next autumn. After the first flowering of *Euphorbia jacquiniædora* is over it will, if kept sufficiently warm, make a second growth that will bloom, and, although the sprays will not be so large as the first, they will be useful for cutting.

Forcing Pit.

Amaryllises, &c.—Where a good stock of these is grown it will be better to have them in succession than in bloom all together. A few of those that completed their growth earliest in the autumn, more particularly the deciduous species, if now subjected to a brisk heat, will push up their flowers quickly. The soil should receive a good soaking of tepid water, or, if the plants be plunged in a moist bottom-heat, and water be supplied in the usual way, it will be sufficient. Plants of *Eucharis amazonica* that have been rested with a view to coming into flower after those earlier started should be brought into the warmest end of the house, and, if possible, plunged in bottom-heat, and, if they are strong and in good condition, they will at once push into bloom. *Imantophyllum*, although more correctly greenhouse subjects, are very effective for general decoration brought into flower earlier than usual by the application of more heat. A few weeks at the coolest end of the forcing pit will bring them on.

Orchids.

Those about to commence the growth of cool Orchids often ask the question what is the best aspect for them. If we take into account the advantage that arises from being able to prevent the temperature running very high in hot summer weather, which is a desideratum I think, there can be no question that a lean-to house with a northern aspect is the best, for, in that case, a thinner shade will suffice when such is required, and an absence of any for a considerable portion of the day, when its presence is needed with houses more under the direct influence of the sun. With Orchids, as with all other plants, the less necessity for shading, the better, but in erecting a house of this description on this aspect, it should by no means be put up to a high building, which necessarily intercepts a very considerable amount of light. I make this remark from frequently seeing a structure of this kind, to accommodate a quantity of costly plants, erected in some position that offered a slight saving as regards first cost, but, taking the value of the plants sacrificed into consideration, the loss in a few years was ten times the amount of the saving in the first instance. The greater portion of the spring and early summer-blooming *Odontoglossums* will now be pushing up their flowers, and continuous watchfulness will be necessary to see that these do not become a prey to slugs or cockroaches; the latter are not usually so troublesome here as in the warmer quarters afforded by the hotter houses, where they increase faster and find more congenial hiding places, but the slugs and snails need to be unremittingly sought after, for, even if destroyed until there is no trace of any remaining, there are others that soon find their way into the houses, come into existence from eggs already deposited there, or that get in with the potting or other material from time to time introduced. Such species as *O. citreum*, *O. hastulabium*, *O. Phalaenopsis*, *O. vexillarium*, and *O. Roezlii* will need keeping in a warmer position than the least heat-requiring kinds. *Masdevallias* which have not yet completed their growth, must have sufficient water to keep their roots thoroughly moist, for their requirements in respect to moisture are almost equal to those of real aquatics, and provided the material in which they are grown is of a nature to allow the water to pass freely through it, the growths are generally finest where the most water is used. I well recollect when *Epidendrum vitellinum* was looked upon as so difficult to manage that few people found it possible to preserve it in a healthy flowering condition for any length of time through the fact of its being grown too warm, but, grown in a temperature suitable for the majority of *Odontoglossums*, little difficulty is experienced with it. Its long, persistent, highly-coloured flowers afford such a pleasing contrast to the light tints possessed by most of the other occupants of the house as to make it desirable

to have a number. The beautiful *Lælia majalis* and *L. albidia* will do well at the warmest end of the cool house.

Preparation for Potting.—It will be well now to see that all material for potting the many plants that will shortly require it is in readiness, by which means the operation will be got through much quicker.—T. BAINES.

Flower Garden.

Auriculas.—Continued severe frost prevents anything being done to these at present; the frames are covered at night with mats, and this must be done every night while frost remains. I have been reading in an old magazine devoted to florists' flowers that all trusses formed about this time should be pinched off, and a horticultural writer recently recommended this to be done even later. In this the old growers were mistaken, for, as a rule, the earliest-formed trusses produce the most perfect blooms. If the trusses of some sorts, such as Lancashire Hero, George Lightbody, Smiling Beauty, Glory (Taylor's), &c., can be seen well down in the axil of one of the lower leaves, even in November, such trusses come on slowly, and are usually perfectly developed. A centre truss with a stem formed at that time must be pinched out. Those who have a heated greenhouse in which to place their plants have a great advantage over those who can only obtain ordinary frames. They ought to be placed in the house this week, and frosts should be excluded.

Carnations and Picotees.—It ought to be well known that these do not seem to be in a dormant state, even at mid-winter. If the weather be mild they make roots and slowly develop leaves. During frosts so intense as to crust the soil in the pots growth either above or below ground must be suspended. Growers of these flowers do not give them that amount of attention which they require during the winter months, and which is especially necessary in February; the plants sometimes begin to spindle for bloom the first week in this month; these will be early blooms, and, if the weather be mild, such plants should be carefully repotted into their blooming pots. The main collection will not be ready for potting until the end of the month. I like to have all the plants thoroughly cleaned before potting them; dead and decaying leaves are unsightly, and must be carefully removed; even in the best-managed collections they are to be found. If sparrows are numerous and short of other food they will peck the tender points out of the plants; if so, it will be necessary to place a net over them as the best precaution. No trace of aphides should be allowed on the plants at this date; it is very dangerous to fumigate the frames after active growth has commenced.

Dahlias.—If a large stock is required the roots must now be placed in heat after they have either been potted singly, or a number of roots placed together in suitable boxes. The best place is a forcing house, where the temperature ranges from 50° to 55° at night. They may be placed over the pipes in Vineries or Peach houses, and be started with them. The shoots start well and healthily over a bed of leaves or tan with just a mild heat.

Hollyhocks.—Instructions for the propagation of these were given last week. See that leaves on plants placed in heated houses do not become infested with red spider; injury is often caused by it before the discovery is made. Seedling or common sorts that were planted out in the autumn must not be quite neglected. If the plants have been mulched round the roots, this forms a safe hiding place for slugs, which will eat the leaves, and it is also very desirable to run the hoe through the ground if it is moderately dry. While frosts last nothing can be done.

Phloxes in Pots.—I would strongly urge the importance of starting the shoots into growth in order to obtain early cuttings. The heat of a greenhouse will cause a very early growth. Shoots about 1 in. long may be slipped off and placed singly in very small pots. They will soon form roots, and grow away freely with a little bottom heat. Those in beds cannot require any attention until the weather is more favourable.

Pyrethrums, Delphiniums, &c., in beds, will be putting forth their very tender leaders as soon as the frost will allow them. See that they do not receive any injury from birds. The plants may be lifted and divided if it be necessary to increase the plants.

Polyanthuses.—As a rule, the treatment recommended for Auriculas applies to these. The trusses on our plants may now be seen rising slowly from the centre, where one truss is generally formed, and two or three more round it. We would remove this class of plants to a cool greenhouse near the glass if it were possible to find room for them. The soil in the pots has been frozen for a considerable time now, but the flowers are most injured by birds in this early stage of development.—J. DOUGLAS.

Hardy Fruit.

The prolonged severity of the weather and consequent scarcity of food for the feathered tribe are already causing them to attack the more advanced buds of Gooseberries, Plums, and Apricots. At present, for some unexplained reason, sparrows are the greatest delinquents, and we have had, much against our will, to resort to the most effectual way of getting rid of them, that is, shooting them. Apparently the buds are not yet plump enough for bullfinches, for, though they alight on the bushes and search diligently they generally fly away with a disappointed twitler. The excessive preservation of bullfinches, sparrows, tomits, thrushes, and blackbirds may be all very well so far as naturalists are concerned, but the cultivator who is expected to produce fruit must, in self defence, shoot some in order to deter others. We had last year a couple of dozen of fine young Plum trees, that were one mass of blossom buds, entirely denuded of them in about a couple of days by bullfinches, and yet, forsooth, we are asked to spare "our feathered friends." Unfortunately for the birds we say shoot them in order to decrease the chance of a fruit crop. We shall now probably have a general spring, and when once the frost releases his grasp vegetation will make rapid progress; it is therefore important that all pruning should be completed as soon as possible, for, to say the least, it seems unnatural to prune when the buds are expanding, and such an operation carried on then must tend, in some degree, to produce constitutional derangement. As regards neglected orchard trees, many would be the better for having their root and stem suckers removed, cankered branches cut off, and other branches thinned out, together with any long spurs, in order that the trees may have a chance of renewing their vigour by the production of new wood; any trees that are affected with Moss or Lichen should be splashed over with a mixture of soot and lime, a simple but sure remedy. A liberal surface dressing of either fresh soil or manure should afterwards be given, and even the first season the fruit will be so improved as to well repay the outlay. Autumnal planting of fruit trees is always preferable, but rain and frost having hindered this, let all be in readiness for doing such work as soon as a change occurs and the state of the soil permits; planting when the soil is in a sudden state is ruinous, no matter how well drained the soil may be. For obvious reasons, in stiff or clayey soils the plants should be raised a few inches above the ground line, but in light or gravelly soils they are best planted on the level, care being taken that in neither case the stems are buried too deeply.—W. W.

Kitchen Garden.

All other things being equal, a well-drained and deeply-trenched garden will yield double the produce of an undrained and badly-cultivated one. The first neither suffers from wet nor drought. The crops can be got in at the proper time, and they require but little cultural attention afterwards, and that little is the more expeditiously accomplished owing to the workable state of the soil in almost all weathers, consequently the crops are finer and earlier matured, whilst, in a garden of an opposite character, seed sowing has to be deferred through the unkind-state of the soil, and this late sowing, coupled with the slow progress made by reason of the water-logged ground, and the difficulties of culture through the ground getting hard and baked by the first dry weather, tends to show the economy there is in deep trenching and effective draining, a large proportion of which may be done in weather when it is not practicable to do aught else. No excuse should be attempted for the neglect of such a duty, moreover, an earnest determination to accomplish it will bring its own reward in the form of assured success. We are still frozen out, but a change seems imminent, and as soon as it occurs, and the ground can be worked, seed sowing should proceed with despatch. After a few early Peas, Beans, and Carrots have been got in on a warm border, space for the main crops of Onions and Parsnips will require attention; both of these flourish best if sown as early in February as circumstances permit. Drill culture is greatly preferable to sowing broadcast for all kinds of kitchen garden crops. The space apart of the drills for Onions should be at least 12 in., and for Parsnips 15 in. The ground for Onions cannot be too highly manured or deeply trenched, but previous to sowing it should be rolled to make the surface firm. Parsnips, on the other hand, cannot have the soil too open, and the manure for these should be buried rather deeply, for no matter how much so they will search it out. Surface manuring for these has a tendency to the production of forked or malformed roots, so that it is better not to manure at all in soils of good or medium quality than to have it immediately under the tops. The November-sown Peas have had a wretched time of it, and look so miserable that it becomes a question as to whether they should be allowed to occupy the ground any longer; should the decision be in their favour, take every precaution to guard them from cutting winds by protecting them with Spruce branches, and from sparrows by netting. Fill up gaps in the early Cabbage plantation, press the

soil about those that the frost has loosened, and as Broccoli has suffered so severely, plant any spare space there may be with plants from the reserve stock. Every bit of green food will be wanted before spring Cauliflowers turn in, and these early-planted Cabbages will prove no mean substitute for Broccoli. Preserve the best piece of ground in the garden for Brussels Sprouts; they should be considered puny unless they attain the height of 3 ft., in which case a peck of Sprouts may be expected from each stem. If an autumn sowing were not made, sow a box at once and raise them in heat gradually inuring them to the atmosphere, in order that they may be pricked out at the foot of a south wall as soon as sufficiently large to handle. On every favourable occasion give abundance of air to Cauliflowers in handlights or frames, and the same remark will apply to all salads, Carrots, and Potatoes. See that the seed stock of the latter are laid in single layers only, and, provided frost be excluded, keep the stores as cool as possible, in order that they may develop strong, sturdy shoots. Such sets never fail to produce fine tubers.—W. W.

Avenues.—Where, as is very often the case, avenues form one of the principal features of parks, they should be pruned and thoroughly put into shape, removing all dead wood. Any trees which are broken or so much injured as to spoil their appearance, must be removed without delay, and replaced by such as will best match those in the avenues. In the case of young trees the earliest opportunity should be taken to restake them where necessary, and in every instance the old ties should be cut and new ones made. Neglect of this often costs the head of the tree during the first high wind after the expansion of the foliage, as during the growing season the old ties, if not removed, will cut into the tree. This is especially the case with all rapid-growing trees, as Willows, Poplars, &c. The most useful tying material which has come under my notice is what is termed jute outtings. This should be cut into strips from 4 in. to 8 in. in width, and from 1 ft. to 3 ft. in length, in proportion to the size of the trees. The cutting is bound round the tree, and tied with house-line or tarred cord. The cost of the former is about £1 per hundredweight, and the latter £3 10s. per hundredweight. These materials will be found effective, durable, and handy. Sometimes, indeed, it is very often the case that some trees will be found to be less vigorous than others, and these should have a good mulching of well-rotted manure; neglect of this will detract very much from the general appearance of avenues.

Tree Pruning, Furze Cutting, &c.—This is the best time for lopping trees and cutting down any timber that may not be required to stand. In cutting out large limbs from trees great care must be taken that the under cut is deep enough to prevent the weight of the branch splitting down the trunk of the tree and bringing away portions of it; this is both injurious and unsightly, and exhibits bad workmanship. Furze may be cut down to within a few inches of the ground if it has grown too high, and, if so dense as to prevent free circulation for pedestrians, openings from 20 ft. to 40 ft. in width should be cut through it in easy curves; this will also prevent extensive fires, which frequently occur in hot, dry summers; in this case the roots should be grubbed up and Grass seeds sown upon the surfaces at the proper season. Drainage requires particular attention this month; where the commons are drained principally by means of open ditches, these should be maintained free from obstructions of all kinds. In the majority of instances, however, the only effectual remedy will be to under or pipe drain those portions which are naturally wet. This is a permanent work, and its effect upon swampy areas is truly astonishing. The making of roads and paths where necessary, trenching for future planting, the general regulation of surfaces, sloping down the sides of deep and dangerous pits, &c., may all be carried on this month. The sooner these works are carried out the more satisfactory will be the results.—CHARLES DENNIS, *Southwark Park*.

Onion Trebons.—This variety was quite new to me last season, but, having obtained a packet of seed of it, it did so well, and proved such a real novelty, that it now must take a permanent place in my vegetable list. With ordinary garden culture the bulbs averaged 12 in. in circumference, many of them being 14 in. It is very handsome, not unlike, both in size and appearance, the imported Spanish Onions. In quality it is super-excellent, having the fullest Onion flavour, and it is deliciously mild. Respecting the origination of it I know nothing other than that the name appears to imply that it is of French origin.—W. W. H.

Early Peas.—Now is the time to sow early kinds of Peas in turf or boxes. If these be placed in any house or pit, from which frost is excluded, and be planted out, when spring sets in they will furnish a crop which will supply the place of those which may have been lost through the severity of the weather.—S.

ANSWERS TO CORRESPONDENTS.

Fuchsia serratifolia.—Allow me to inform Mr. Johnstone (p. 92) that I grow this Fuchsia, and will be pleased to supply him with a few cuttings for another start if he is anxious to continue its growth. It is well always to keep a few duplicates of such plants in store pots to fill up any vacancies which usually occur after so prolonged a frost as we are experiencing this year.—A. HOSSACK, *Ragley, Alcester*.

Large-leaved Saxifrage.—Allow me to say in reply to Mr. T. Williams (p. 92) that it was the common London Pride which I had in view when I wrote *Saxifraga oppositifolia*. The London Pride and *S. Germ* are only competitively large-leaved, but they grow tall, and when they are in good health are really large leaved or have the same effect. Their flat leaves spread out in broad rosettes have a fine effect about the stems of large Lilies, as well as in large patches on the rockery, and neither of them require much root room, as they are surface-rooting plants.—W. D., *Dublin*.

Insects.—Is the small fly that burrows into the soil and flies about amongst pot plants infested with green fly the winged aphid?—ANON. [It is difficult to answer your question. The winged aphid might fly about, but the burrowing into soil is a puzzle. Cannot you send a specimen of the small fly when something positive might be said about it.—W. W. S.]

Rheums.—I notice an enquiry in your issue of January 11 (p. 48) as to the difference between *Rheum palmatum* var. *taugentium* (Max.), and *R. officinale*. The leaves of the former are much more deeply cut and of a darker colour. Your correspondent will find a good figure of and of the latter in Regel's "Gartendora" for January 1875, and of the latter in the "Botanical Magazine," December, 1874. The former may be seen growing at Chelsea Botanic Garden, and at the Botanic Gardens Edinburgh; and the latter at Kew and Regent's Park Botanic Gardens.—E. M. HOLMES.

Conservatory Climbers.—It would, perhaps, be impossible to name a more welcome plant than the *Luculia gratissima* which Mr. Culverwell recommends (p. 92); still from the position to be occupied by it it has its drawbacks, one of which is its only flowering for a limited time, and such positions are often expected to be kept gay nearly the whole year round. I would recommend your correspondent to try *Hambostrum* elegans planted out, the lateral shoots being allowed to hang naturally. Nothing could be more pleasing, and it flowers quite ten months out of the twelve; moreover, its not being liable to be infested with insects is much in its favour; and, finally, this plant is well adapted for covering a large space in a very short time.—A. HOSSACK, *Ragley, Alcester*.

Names of Plants.—J. B.—1. *Adiantum Santa Catharinae*; 2. *Kennedyia monophylla*; 3. *Alonsoa Warcewiczii*; 4. *Selaginella cesia*. R. H.—*Eranthemum atropurpureum*. Jo'n Gordon.—We do not know of any one requiring them.

Transplanting Vines.—I am thinking of moving my Vinery, and wish to know the best time to do so; also if Vines that have been planted six years could be lifted with safety, or would it be best to plant young Vines.—J. R. [When the crop is cleared off the house may be moved, as exposure to the weather will not then injure the Vines. Should sharp weather set in before they can be lifted they may easily be protected by being tied together and covered with hay or Fern. Move them when the weather is open, taking care not to injure the roots during the operation. Shorten back any strong, coarse roots which they may have, plant, and start them gently at once. Allow plenty of growth the following season, and do not crop too heavily. Such Vines in good health now will do good service immediately, whilst young ones planted would require three years to get fairly established. We have lifted Vines twenty years of age in the way described, and with the best results.—S.]

Questions.

Lady's Slippers.—Having found much difficulty in flowering *Cypripedium* insigne in a satisfactory manner, allow me to enquire as to the most approved treatment of this fine old Cypripedium. Some of my friends flower it most abundantly every year, and as I treat my plants in a similar way I am quite at a loss as to the cause of my non success. Can any one help me?—CLITTON.

Eucalyptus amygdalina.—Has this been tried in the British Isles? I rather gather from Mr. P. Grieve's remarks (p. 61) that it has not yet been introduced. The temperature at Rome referred to by him, viz., 6° below zero, is evidently measured in Centigrade, which is more frequently met with on the Continent than Fahrenheit, which would make 21°·2 of the latter, I think. Frost to the amount of 38° is quite unknown in Rome; even 11°, as above, are unusual.—J. H. W. T.

Mushrooms in Frozen Beds.—Can any one tell me what prospects there are of a crop of Mushrooms from a bed which I have in an outlying wooden shed. It was spawned on the 25th of October, and by the beginning of December the spawn had worked through the bed in such a manner that I felt sure of a heavy crop. The severe frost prevented all access to the shed until the first slight thaw came when I found there had been 6° of frost inside, and the surface of the bed frozen. The bed was made in the centre of the floor, with space round it for fermenting material, of which there was about ten barrow loads in at the time. I should be glad of information on the subject.—R. N. W.

SATURDAY, FEBRUARY 8, 1879.

[Vol. XV]

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

THE TEA-SCENTED ROSE.

(Continued from page 81.)

Then will I raise aloft the milk-white Rose;
With whose sweet scent the air shall be perfumed.

Shakespeare.

THAT philosophic hero, the elder Pliny, immortalised as a scholar and a statesman, as a soldier and a sailor, who had such an appreciation of the value of time that he would dictate to his secretary while putting on his *toga* (in our vulgar parlance "togger"), and was very angry with his nephew, Master Pliny, junior, because he took a walk for the refreshment of his body when he might have been improving his mind—that ardent lover of science who, seeing from his ship, when in command of a fleet, an eruption of Vesuvius, immediately set sail for the scene, and, heedless of warnings, could not be happy until he got himself well into the molten lava and mingled his ashes with those of the mountain—Pliny, the historian, tells us that the land we live in was called Albion, either from the white cliffs, which the sea washed (*ab albis rupibus, quas mare albu*), or from the white Roses with which it abounds (*ab albis rosas quibus abundat*). Be this as it may, the record suggests a beauteous vision to the roseate mind, thickets and hedgerows of the pale wild Rose, untouched by the chopper of model farming, or by the brierman's spade, and, here and there by the infrequent habitations of man, those larger and more double varieties, which were the results of selection and of cultural care. Yes, it is a pleasant thought that 1800 years ago (Pliny died A.D. 79) and doubtless many centuries before, our beloved fatherland was the land of Roses, and that from Cornwall to Cumberland (aye, and far beyond, for who shall dare to doubt that there were Roses in Ayrshire?) these "stars which on earth's firmament do shine," shone in countless beauty like the stars of heaven.

White Roses! Off again from Scotland to England, and from the first to the fifteenth century, we are reminded, as we linger at York, of the fierce frays fought in England, *ob albas rosas*; and we are glad to move on, by one of those rapid flights of fancy, which make the telegraph a mere tortoise, over 400 years, in two seconds, and to see the white tents raised by the ancient city, on Knavesmire or Bootham Field, not for scowling warriors, but for smiling dames; not for the coat of mail, iron gauntlet, and dented helm, but for *robes de soie, gants de Paris*, and the last sweet thing in bonnets. A battle, it is true, is fought in those tents; nay, more, a War of the Roses, but there is no weapon more formidable than a thorn, and nothing to remind us of ancient enmities except a Special Prize (offered, so far as I know, at York only) for White Roses.*

White Roses! Off again, in that swift conveyance, which passes the Flying Scotsman and the Flying Dutchman, "as though they were standing still," returning to the place from whence we came, let us diverge, ere we come towards Land's End, to the left, and imagine ourselves at a place and time (the place is Plymouth, and the time some thirty-five years ago), when Devonians, the white Rose of England—not milk-white, but cream-white, *blanc jaunâtre*, as being *crème de la crème*—delighted the eyes and noses of all who could see or smell. Oh! happy Mr. Foster, to foster such a babe! Who would not be a nurseryman, with such a child to nurse? Gardeners, amateur and professional, came in crowds to gaze in sweet amazement, and went home to ask their envious friends kindly to abstain from the subject of Roses in their presence, because it was impossible for persons who had not seen Devonians to know anything whatever about them. Even in Devon, so full of beauty, animate and inanimate, celebrated alike for landscapes and lasses (I

remember a visit in my undergraduate days, and how I fell desperately in love with fourteen peerless belles), even in Devon this Rose was a gem supreme. It is difficult to realise in its most attractive phase, but its very failures charm (how lovely, for example, its small undersized buds, which have been cut from some weakly plant, and its peep amid the Camellias, Eucharis, Pancratium, and Orange flowers of some vast bridal bouquet!), and to see it once in the full grandeur of its beauty is a memory for life. Such a consummation is, perhaps, attained most quickly and easily upon the climbing variety of the Rose on a warm wall, or in a Rose house, but of this hereafter. Once thoroughly established, it thrives admirably on the seedling Brier, but I have seen it in its glory before the scendant "sport" or the seedling Brier were known. and I remember a grand box brought to our first National Rose Show in St. James' Hall, from its native country, by Messrs. Veitch, of Exeter, more than twenty years ago.

The honoured name of Veitch (and he who honours it not must know little about beautiful plants) appropriately suggests the next Rose on my list, the Duchess of Edinburgh, introduced by Messrs. Veitch (at a drawing-room of the queen of flowers) in the spring of 1875. The Rose somewhat reminds us of the old Crimson China, and has more of the India than the Odorata in its constitution. It is prettily shaped, and glows with a clear, vivid, carmine—*rouge carmine* as the French catalogues have it, but we in England like not the word *rouge*, except so far as it concerns plate-powder. It is an excellent pot Rose, and may be brought into bloom, by judicious forcing, in the very early spring—I mean in its true character, for I make no count of Roses so drawn and weakened by artificial heat that their own mothers—I mean raisers—would not know them, would not recognise their pale, puny flowers. Out-of-doors, moreover, it is very effective, being one of the few red Roses in the Tea family; one of a trio, in fact, its companions being Aline Sisley and Cheshunt Hybrid, and so by the striking contrast of its colour with the whites and the yellows, the buffs and the pinks around, adding much to the beauty of a bed or border of the lovely Tea-scented Rose. A capital likeness of the Duchess of Edinburgh will be found in the Portrait Gallery of Illustrious Flowers, No. 217, Plate III., which is in the possession, or ought to be, of all who love THE GARDEN.

Homer, by a slight anachronism, comes after the Duchess of Edinburgh, and who deserves so well as he, enthroned three thousand years first king of the poets, a crown of Roses? His namesake has its pale pink petals frequently edged with a deeper rose, crimson tipped, like Burns' Daisy, and like the fingers of Aurora, as Homer himself describes them. And does he not tell us, towards the end of his "Iliad," how when Venus and Apollo would preserve the dead body of Hector from the dogs and from the drought, they could think of nothing so efficacious as the oil of Roses, with which they dressed him accordingly, thus typifying, in a charming allegory, the appreciations which Beauty, and Art, and Poesy, and Valour have ever felt for the Rose. Homer is one of the hardest of the Tea-scented Roses, but I am bound to confess that, although I never could bring myself to believe that the great poet, with all his marvellous powers of description, was blind, his synonym is happiest when near a wall.

To leave the goddess Venus for Isabella Sprunt seems to indicate a want of respect and good taste, and the antithesis has an abrupt and discordant sound; but there is, on reflection, no great incongruity, for both are beautiful. As Shakespeare sang of his beloved Ann Hathaway, "She hath a way," so might Miss Sprunt's accepted lover say of his *fiancée*, "She is-a-belle." Not one of those irresistible Queens of Hearts, who overpower us like Venus, or Catherine Mermet, or Comtesse de Nadaillac, or the Fair Devonian, but pretty and *piquante*, in her *première jeunesse*, that is, in her budhood, in her well-shaped, abundant, pale-yellow buds.

Jean Ducher and Jean Pernet are, as we should expect, Roses of quality. I say in accordance with expectation, because whenever "our lively neighbour, the Gaul," acquires a new Rose, and bestows upon it his own name, or the name of his kinsfolk, or of a French friend, there is, unless parental prejudices have blinded his eyes, a special merit in the flower. Take, for example, Auguste Rigotard, Charles Verdier, Claude

* I see in this year's schedule of prizes, to be given at the Great Yorkshire Gala in June, that yellow Roses may be shown with the white.

Levet, Dupuy Jamain, Etienne Levet, François Lacharme, Hippolyte Jamain, Jean Ducher, Jean Liabaud, Jean Pernet, Jules Margottin, Mesdames Eugénie Verdier, Hippolyte Jamain, Lacharme, Margottin, Thérèse Levet, Victor Verdier, Marie Beaumann, Pierre Notting, and C. Crapelet. I commend this laudable ambition to be associated with that which is beautiful, rejoicing, nevertheless, that Mr. George Paul, of Cheshunt, either did not feel, or resisted, its influence when he immortalised his friend and brother, and gave the name of Reynolds Hole to a Rose which, at the last exhibition of "the National" at Manchester, was the *spécialité* of the show, and might have assumed the proud title which some of us may remember as belonging to one of our old friends, the Gallicas, *Rien ne me surpasse*. Jean Ducher, by some oversight, is not in my collection, but the reliable Rosarians, English and French, are so united in praise that I cannot omit it from my list. Of Jean Pernet I speak from happy experience, as being one of the most beautiful of the Tea Roses, a soft pale yellow in colour, substantial and symmetrical in form. La Boule d'Or (no connection with the golden ball of the pawnbroker) is even yet more attractive, larger, and of a deeper golden-yellow. Never to be forgotten are those glorious blooms, which one of the great champions of Rosedom—Mr. Cant—brought to the National Show last summer in the Palace of Crystal. He says, I see in his last catalogue, of this Rose, that it is "very beautiful when grown under glass," but this must not deter the amateur from planting it among his outdoor Teas, because I have grown it and shown it, in its integrity, from its home in the open. This is more than I can say at present of Letty Coles, the next Rose which comes under our notice, for though I have grown it with the assistance of the glazier, carpenter, potter, pipe and boiler maker, and coal merchant, in a very charming form; a Madame Villermoz, with the centre petals of a rich rose-purple hue, I have not succeeded in edging *à fresco* the charms which it reveals under glass. Perhaps some more congenial season may "bid her come forth, and suffer herself to be admired" in our gardens. At all events, I must speak her praise, if only in affectionate remembrance of "that good grey head which all men knew"—of John Keynes, under whose auspices Letty Coles made her *début* in the world of Roses; and, to many of us, who often think of him with a sorrowful regret that we shall hear his hearty, honest words no more, it may be a solace to read them, to read again that which he wrote in the Chronicle of the gardener concerning this very Rose.

"Some three or four years ago, from information received, I was induced to go and see a Rose whose characteristics were described to me as something out of the common way. The Rose had bloomed three years in succession, always preserving its special features. I went, I saw, I won my prize, at the expenditure of a large sum of money. My acquisition had four "eyes," to make sure of them I destroyed the rest of the plant. The sport, for sport it was, was evidently a Tea Rose of unusual merit. On my homeward journey I wrapped my treasure in a piece of newspaper, and placed it by my side on the seat of the railway carriage, together with another travelling companion, my umbrella. Towards the end of the journey, however, I was called into another compartment to speak to a friend, and with him I rode to the end of the journey, some eight miles, leaving my packages behind me. What was my dismay on returning to the carriage I had quitted *en route* to find neither Rose nor umbrella. Here was a catastrophe! My money sunk, my anticipations blighted, my umbrella vanished, my beautiful Rose annihilated. What could be done? I remembered that I had left two men of very suspicious appearance in the carriage, but I had no idea that in one stage of about eight miles only I could have possibly lost these things. It struck me, however, that these men had my Rose and my umbrella too. The station at which I alighted was contiguous to another on a different line of railway, so I at once hastened to that other, but, alas! I could see no trace of the two men. On proceeding further, however, up in one corner of the station there was the newspaper with the Rose in it safe and sound. The recovery of the Rose emboldened me, and gave me hopes for my umbrella. I was determined, if possible, to regain that also. I waited until the train was ready to start, when, as I expected, my former travelling companions appeared, one of them carrying my umbrella. I speedily regained that also, and my despair was converted into joy. And now let me tell you the name of the Rose—it was Letty Coles. Never was a fine Rose so nearly lost to the lovers of Roses as this flower. I con-

sider it myself wonderful, for had that paper parcel been thrown away the Rose would have perished, and Letty Coles would have been—nowhere. From those four eyes, however, the Rose has been propagated and distributed. It was a sport from Madame Villermoz, and fine flowers will, I trust, be exhibited this year.—*John Keynes, Salisbury, July, 1877.*"

Another incident of a more amusing character I quote from "The Six of Spades" (familiar as that admirable book must be to all well-educated minds): "Gentlemen," he said, when speaking at a large dinner of horticulturists in London, at which I had the honour to preside, "you are all enthusiastic florists, and you will be pleased to have an example of floral zeal. I knew an exhibitor of Carnations and Picotees, who, in stepping out of his cart at a show, stumbled and broke his leg. He persisted, notwithstanding this fracture, in staging his flowers, and after this he remained for three hours in the vicinity of the building in which the exhibition was held, without consulting a doctor until the awards of the judge were known."

I need only say that this extraordinary instance of floral worship evoked the astonished admiration of the company; but when the narrator quietly added, as he slowly resumed his seat, "It was a wooden leg, gentlemen," I shall never forget the perplexed expression of his hearers, the momentary indignation resenting the deception, and then the unanimous outburst of mirth.

Alas! I have a letter before me, written by "The touch of a vanished hand" in which he says, "The incident of the leg was a literal fact; the man's name was Strong, and we showed Pinks together near Winchester." S. REYNOLDS HOLE.

(To be continued.)

THE ROSARIAN'S YEAR BOOK FOR 1879.*

This small quarto, consisting of 80 pages, is a great improvement on that issued last year. It contains original articles written by some of our best known Rose growers. Amongst them are rules for judging, selections of the best Roses, new Roses, and much practical instruction as regards the culture of the Rose, both as a standard and as a dwarf, on its own roots, and on every kind of stock. The following, on Dwarf Roses and their winter management, by the Rev. C. P. Peach, may prove interesting to our readers:—

The winter management and pruning, top dressing, &c., of dwarf Rose trees, necessarily at once raises the question of soil, climate, and character of stock. I confine these remarks almost entirely to dwarfs, because year by year I am more than ever prejudiced (some would say) against standards, but my own observations in my own and friends' gardens, and in those of nurserymen, lead me more decidedly to the conclusion that, except under exceptional circumstances, all standard Roses deteriorate after the third year, and the very method of pruning required to form a symmetrical head, as it is called, militates against the production of first-class blooms. No doubt some of the stronger growers may be made handsome on each side of a walk by being trained down like weepers upon a circular frame of wire, as in that case the weaker wood can be cut out, and only the stronger shoots from the centre tied down, when strong enough to bear it; and, though this is following a system of training contrary to the nature of the Rose, yet I have seen several cases where it has been successful. My experience, however, has been this, that whenever I have looked over a garden with transplanted standards and dwarf standards, growing we will say in beds, or up the sides of kitchen garden walks, or as the back and second row of a Rosarian, I have invariably found the greater proportion unsatisfactory. This is, no doubt, in a great measure accounted for from the treatment which the poor Bear stock has to bear, from the time of its being cut out of a hedgerow by a labourer with a draining spade, then laid in heaps in a shed, then planted in nursery rows; no real attention being given to selecting those that have a fair amount of root, and clean straight stem, and eventually all that push any shoots, whatever are budded, and all that live through this process are sold, and after a second transplanting have further difficulties to meet with; upon these I need not enter. I have, however, another sentence against them in these northern climes, and that is, that in severe weather it is almost impossible to protect them against sudden frosts. In the winter of 1859-60, before I had a taste of what a real Yorkshire frost meant, I lost 98 out of 100 standards I then possessed; and

* "The Rosarian's Year Book for 1879." Edited by the Rev. H. H. Dombrain, London: Bemoose & Sons.

though every Rose, with few exceptions, on the Manetti, were killed down to the ground, yet every one came up again from the base in the spring, and before the year was out were re-established. I determined from that time never to trouble myself about standards again, but a friend of mine sent me a dozen a few years afterwards as a present, not one of which survived another frost of a like kind, which came upon us suddenly, after a very open December, on Christmas Eve, when Ivy leaves which I went out to gather for Christmas decoration, snapped off by their stems like pieces of glass; and Oak trees were cracked in damp clay land by the sudden action of the frost before the sap had fairly descended. I owe a grudge too against this same frost, as it killed a *Maréchal Niel* against a south wall, even though it had a glass coping over it at the end of a fruit wall, and was in a sheltered place, and covered a space of wall about 20 ft. long and 9 ft. high. This is a long digression to begin with but I make it in order to say that my remarks apply almost exclusively to dwarfs on the Manetti, which, after proper planting and treatment are virtually established on their own roots. My experience with Manetti stock began before I came into Yorkshire (some 24 years ago), and while I was in Nottinghamshire on a light red loam, rather sandy, but still deep, and a good soil, especially for evergreens, as Hollies, Rhododendrons, &c. In planting a garden there for a near neighbour, a lady, very fond of flowers, I first tried at the recommendation of a friend, Roses on the Manetti; they were tried in conjunction with tall and dwarf standards, but only two years' experience convinced me that for permanent planting in light soils, and I may add for all ordinary garden soils, the system of growing dwarf Roses on the Manetti, which afterwards get established on their own roots, is more satisfactory. I will add a few words on the seedling Brier as a stock later on. The winter management of dwarf Roses divides itself into, I may say, three heads; first, method of pruning; secondly, of protection; thirdly, of nourishing, &c. With regard to pruning, I am not an advocate for pruning closely too early. All Roses should be gone over after the first bloom is over, and all weak growth removed, then about the middle of November any very rampant shoots may be shortened, the beds raked over after the fall of the leaf, I do not mean to say of all the leaves of the Roses, for many will remain on in spite of wind and rain and frost much later, but after the great bulk of the deciduous trees, whose leaves blot about a garden, have shed their autumnal foliage. This is a good time to see if any are so much worn out as to require replacing; there is no worse policy with the queen of flowers than to keep unsatisfactory old plants; and, as a rule, there is no better time for planting than the middle of November, the earlier the better if the season is favourable. I am not an advocate, especially in light soils, for digging the beds; let them be very lightly and slightly forked over with a steel fork, and no manure put on the beds till the middle of December. This gives the stems and roots of the plant more advantage of light and air. About the middle of December well decayed old hobbed or farm yard manure, especially from the pig styes, where pigs are being fed and fattened, may be put over the beds, and then covered over with longer manure, or even light Barley or Oat straw. Should the Rose garden be unfortunately exposed to wind, one of the most fatal things to success in growing good Roses, then all strong shoots partially shortened should be tied, and the longer manure may be kept in its place by pegging it down with Osiers or Hazels; one good way is to lay the Osiers or Hazels, or even long tile laths on the manure between the plants, and peg with galvanised wire pegs, which can be easily bent out of No. 15 to 18 wire, such as is used for straining to walls to tie in fruit trees. As a rule, however, it is almost useless to try and grow even dwarf Roses on the Manetti, Seedling Brier, or their own roots in places too much exposed to the wind. Where difficulties of this sort have to be contended with, hedges of Hornbeam or clipped Yew may be grown as protection with advantage. I am not venturing to make these remarks for an experienced Rose grower; in fact, from such I have more to learn than to teach; but as a warning to amateurs who have not had long experience. The opposite extreme, of too much shade and too crowded planting, or being subject to the inroad of roots of trees, &c., is in its way as bad; but it is to be hoped by this time very few who love the Rose would subject it to this treatment. Nor again, in these few records of observation and experience, do I venture to give advice to exhibitors, who are competitors at the larger shows, but to those who are content to grow Roses for their own amusement and interest, and to exhibit in the smaller classes, or at local shows, to increase their zeal and to measure their strength. In the more severe contests between nurserymen and noted amateurs, the blooms are mostly cut from maiden plants, whether on the standard or seedling Brier stock or on the Manetti. Still I venture to affirm that if proper care and attention is given to Roses as dwarfs in ordinary garden soil, good and perfect blooms may be picked for many years from the

same plants, which will with difficulty be beaten even by selected blooms from large quarters of maidens. As a rule, no further attention is required for the Roses till the returning spring begins to awaken new life. Then comes the final pruning, but first remove the longer manure about the end of March or beginning of April. The stiffer the soil and the colder the climate, the longer the covering may remain. Try, too, and choose a dry time, and see that the beds are not trodden over more than necessary. In nearly all kinds of dwarfs, whether on the Manetti or seedling Brier, it is advisable to cut away all wood more than two years old. Shorten the shoots on the growth of the older wood left (which will be the side branches) more than the stronger shoots of the previous year's growth. In pruning dwarfs early in a doubtful season, it is wiser not to prune too closely at first; but we should never be afraid of cutting away weak wood, or any that appears damaged by the winter. But my experience teaches me that it is better to prune too late than too early; but in the summer, in the south of England—more especially in the south-west—earlier pruning is admissible, if not even advisable. Should, however, late spring frosts prevail, or, as is often the case, recur again in the beginning of May, after an interval of a warm April, it is a great advantage to be able to re-prune, and find sufficient uninjured wood and buds left. Contrary to what many persons would expect, strong growth of the previous year is more able to resist frost—especially spring frosts—than older wood. For instance, many persons would argue that because a Dog Rose in a hedgerow is indigenous, a native plant, it would be more hardy than an imported Rose; but in three different winters I have noticed Dog Roses (the Hedge Brier) killed, while garden Roses of the hardier sorts have stood the frosts, and only the younger shoots of the Brier have survived—what most persons would have called succulent. I have never yet, strange to say, seen strong shoots of Manetti stock injured by frost. After taking off the longer manure and pruning the plants in the spring (say, from the middle of March to the latter end of April, according to the season, situation, and soil) then, after taking off the prunings, fork the beds slightly, so as to cover over any old, well-decayed manure left on the surface, but do not disturb the roots of the Roses more than can be helped, and, above all things, avoid a spade. I venture, too, to add, avoid as much as possible liquid manures and constant waterings: no doubt there may be some soils where it is almost necessary, but, as a rule, where there is a sufficient depth of soil, and where proper manure has been given in winter, and the roots of plants are not disturbed, the goodness of the manure will be washed into the ground by winter rains and snows, and the roots will go in search of it. Newly-planted Roses may occasionally require water, but though I water *Calceolarias*, and *Verbenas*, and *Lobelias* when first planted, I have never watered Rose beds, and see no necessity for it. It is a different thing with regard to climbing Roses against a wall, which can only get rain from one quarter, but I am convinced in my own mind that watering Rose beds only induces plants to make too much surface root, and water becomes at last a necessary requirement, and hot, dry weather leads to green fly and other ailments. I do not grow Roses largely—never, perhaps, having more than 1,500 plants at a time—but I have hardly suffered at any time, in the driest seasons from greenfly, though occasionally leaves will mildew and have black fringes to follow; but it is oftener from cold and damp, than want of moisture at the roots. Mine is only a light loam on a pure sand, but by plantings and shrubberies I am protected from winds, and, except in some positions, no Roses have the full sun the whole day through. Of course there are soils, especially where the subsoil is gritty and porous, where spring and summer watering may be necessary, but when I read of persons recommending constant watering, and eternal syringing with soap-suds from the laundry and liquid manure from the stables, I am inclined to say that they would over-egg the pudding. At all events, if water has to be given, do it thoroughly, not too often; let it get to the extreme depth of the deepest roots, and add good liquid manure, with a little guano and superphosphate. Constant dribblings are most fatal to the well-being of a dwarf Rose.

Now, as to the seedling Brier, my friend, our president, is all in favour of it. I have no doubt that in strong clays and wet, cold land, where the finer roots of the Manetti perish from cold and damp, the seedling Brier, if budded the third year from its first growth, will be a most valuable stock. If, after transplanting, the plants are put sufficiently deep in the ground, the difficulties arising from root-suckers may be avoided.

I do not believe that Manetti stocks are too strong for the weaker Tea Roses, but that Tea Roses on strong lands have not sufficient strength of wood to give root action to the Manetti; and their inclination is to throw up bud-shoots from the base, just as seedling Briers are inclined to throw up suckers. I have not, certainly, tried many of the seedling Brier, because my land is not suited to it, though it is undoubtedly better than the hedgerow standard. But in most garden soils (for the generality of soils are neither heavy clay, unc-

tuons loam, nor blow-away sand) the office of a stock is to supply roots and extra roots, till the scion is established, and well established on its own.

The seedling Brier does not naturally push so early as the Manetti, and, as Teas are inclined to be forward, budding on this stock helps to backward them: and in the case of H.P.s, exhibitors will always find that their seedling Briers will give them blooms for their later exhibits when their Manetti stocks are failing them. But in the winter management and pruning of Roses on the seedling Brier stock, I am inclined to think that, as the growth is generally shorter, the pruning ought to be later and more severe, and the mulching material kept on later. The roots of the seedling Brier are far thicker, but less numerous than those of the Manetti, and require stronger and more tenacious soil; and I believe it is a mistake to let these seedling Briers get too strong or too old before budding; and when transplanted, they should have the scion buried as deeply as that on the Manetti—at least 3 in. to 4 in. in light soils, and 2 in. to 3 in. in heavy. It seems to me, in these days, with greater knowledge and observation, to be afraid of Rosarians having their Roses injured either by Manetti shoots or Dog Rose suckers, is no longer a theme to be harped upon; but I still maintain that the Brier is more inclined to throw up suckers, even on the seedling, than a properly dis-budded Manetti stock is to throw up shoots from the base. A practised eye will readily see and discover either, and one who cannot see the difference between the shoot of a Rose—whether H. P., Tea, or Bourbon, &c.—and a Manetti or Brier, has not much observation.

In spite, then, of the verdict of many of our leading Rosarians—notably our president—I am inclined to think that it is only on strong and heavy soils, or wet, unctuous land, that the seedling Brier, as a stock, has any advantage over the Manetti, and that if Roses on the seedling Brier, like Tennyson's brook, "go on for ever," it is when they have established themselves on their own roots, or where their growth is strong enough to afford sap to the Brier stock, as well as their own roots, without the constant attempt to throw up suckers. My own impression still is, that the majority of garden soils—especially when under long cultivation, and with the constant addition of leaf mould and decayed manure, naturally accumulating in a garden soil to form humus—are not to be characterised as heavy and wet soils; and I am equally convinced in gravelly, stony, or calcareous soils, the seedling Brier has little chance against the Manetti. I do not think a sufficient trial has been given to the Celine, and I see no reason why other stocks may not yet be found with clear bark, fine roots, and healthy growth, which may supersede either.

I conclude these notes by saying, that as the natural inclination of a Rose is to throw up young growth from the base, and so recuperate its strength, and as these stronger shoots give the finer blooms, so in the general management of the Rose, both in pruning and culture, every encouragement should be given to those stronger shoots, and all the older wood removed from time to time—especially at the first winter pruning, and with due care, the same Rose plants will continue for years to give blooms which will not disgrace the best exhibition stands.

AMERICAN NOTES.

Excellent Protection against Rusting.—For garden implements of all kinds, having metal surfaces exposed, for knives and forks, and other household apparatus, indeed for all metals likely to be injured by oxidation or "rusting," we know of no simpler, more effective application than that furnished to the "American Agriculturist" by the late Professor Olmsted, author of "Olmsted's Natural Philosophy," &c. He used it on air-pumps, telescopes, and various other apparatus.—Take any quantity of good lard, and to every half-pound or so, add of common resin ("rosin") an amount about equal to half the size of an egg or less—a little more or less is of no consequence. Melt them slowly together, stirring as they cool. Apply this with a cloth or otherwise, just enough to give a thin coating to the metal surface to be protected. It can be wiped off nearly clean from surfaces where it will be undesirable, as in the case of knives and forks, &c. The resin prevents rancidity, and the mixture excludes the ready access of air and moisture. A fresh application may be needed when the coating is washed off by the friction of beating stumps or otherwise.

The Scarlet Monkey-flower (*Mimulus cardinalis*).—In the Atlantic States we have two native species of *Mimulus*, but their pale purplish flowers are not showy. In Michigan and westward there is a yellow-flowered one, and still further west the number of species increases, until on the Pacific coast they become so numerous as to number about twenty-five. Probably the best-known *Mimulus* is *M. moschatens*, the Musk plant, so often abbreviated to "Musk" that many suppose that the drug with all-powerful odour, some call it per-

fume, is obtained from this plant, instead of being unpleasantly animal. The scarlet Monkey-flower, a native of Oregon and California, has been in cultivation for nearly half a century, but, like many other good things, has been pushed aside by newer comers. We saw it in its wild state many years ago, but never happened to cultivate it until last year. The plant was unintentionally left out last fall, and, as the succeeding winter was unusually mild, it came up last spring with great vigour, and has all summer given a continuous bloom, which has not ceased up to the time we write (Oct. 25). It cannot be relied upon as quite hardy, and it is safer to make new plants from cuttings to keep over the winter in the greenhouse. In its native localities the plant is 2 ft. to 4 ft. high, but in cultivation is rarely over 1 ft., and, as it branches freely, is about as broad as tall. The stigma of this flower (the terminal portion of the pistil which receives the pollen) is very sensitive. Instead of a blunt end or knob, as in most flowers, the stigma consists of two egg-shaped plates; these spread apart when the flower is in "full blow," but whenever pollen falls upon the inner surface of these plates they suddenly close; they are so irritable that the same movement takes place when they are touched by a small splinter or any other hard substance.

Straw as Fuel.—The European Mennonites, whose religion prohibits bearing arms, have within a few years come to this country in large numbers, and have formed already prosperous colonies in Kansas and other Western States. In their new homes they follow their former pursuit—farming, and many of them brought with them the implements they formerly used, affairs so quaint and cumbersome, that they appear more like a collection of antiquities than articles for real use. Besides their farm implements, they brought over their household effects, conspicuous among which are a large clock to hang upon the wall, and a huge, curiously ornamented chest to hold the household treasures; these are to be seen in almost every Mennonite home. Though they could not well bring their enormous stoves to their new homes, they have brought their domestic customs with them, and the house in Wisconsin and Kansas is heated, and their meals are cooked in the same manner that they were in the old home in Russia and Prussia. "The Americans burn money, we burn straw," says the Mennonite settler; how they manage to keep warm in winter, and to cook the year round with no other fuel but loose straw, is a mystery to the average American. The Mennonite immigrant, when choosing a locality, is quite unconcerned at the total absence of timber, and will settle many miles from wood or coal, with indifference as to the fuel question, in localities where an American would never think of making a home. He sees fuel for the first year in the miles of grass about him, the second and succeeding years he will have the straw from his crops, and straw stacks are his favourite substitute for the wood-pile and the coal-bin. We first saw straw in use for fuel at the house of a Russian Mennonite bishop in the colony in McPherson Co., Kansas. Dinner for four of us was to be prepared. A vigorous young Mennonite girl vanished with a bushel basket, and returned with it full of loose straw, then placing her kettles, &c., on the top of the cooking range, opened the fire-door, and thrust in two large handfuls of straw, touched the match, closed the door, and the kettle commenced singing almost immediately. The fire was 'dead out' before the dinner was half consumed.

The Graceful Sunflower (*Helianthus orgyalis*).—Those whose knowledge of Sunflowers is confined to the common annual species (the Sunflower) can hardly conceive of a graceful one. Some plants appear to be associated with certain surroundings, and to belong to shiftless, "ne'er do well" people. The dwelling of such is often surrounded by a dilapidated fence, within which Sunflowers and Love-lies-bleeding suggest that even in a house where old hats and rags supply the place of window panes there is some one who has a love for flowers, however coarse they may be. But all Sunflowers are not coarse, and while we admit that there are many unattractive ones, we claim that there are a few really desirable species. Among the most interesting and showy of the many Sunflowers is *Helianthus orgyalis*. *Helianthus* is easily translated into Sunflower, but when we came to find an appropriate equivalent for *orgyalis* we were puzzled. The word means the height of a man, but Man-high Sunflower, or even Six-foot Sunflower, would hardly do. In considering what name would be best for a plant likely to become more or less popular, we were glad to find the difficulty removed. In "Hardy Flowers," a name—the Graceful Sunflower—which is not at all inappropriate, has been given it. We had known this species for several years, but had not especially noticed its beauty until we saw, the past autumn, at the Cambridge Botanic Garden, a fine clump of it, 10 ft. or 12 ft. high, where it was contrasted with a large number of other species of Sunflower, and easily outshone them all. For clumps upon a lawn this is a most effective plant, and, from its height, it may be used for the centre of ornamental groups of bold plants.—"American Agriculturist."

THE FLOWER GARDEN.

THE GREEN HELLEBORE.

(HELLEBORUS VIRIDIS).

THE Hellebore represented by the annexed illustration may be taken as the type of that group of Hellebores which are characterised by their deciduous leaves, produced on erect stalks, being circular in outline, and invariably split up into several more or less narrow divisions, and bearing blossoms varying from green to purple on forked stems. Though they cannot claim to be considered as showy garden plants, yet their handsome verdant foliage and the property which they possess of delighting to revel uncared for and undisturbed in shady places admirably adapt them for planting by the sides of woodland walks, or in company with similar subjects in the wild garden—in short, any place where the soil is not too poor, or the position too much exposed. *H. viridis* is a widely-distributed plant in Western Europe, besides being one of our native wild flowers. Though somewhat rare it is found growing in company with the common Columbine and the rare *Actæa spicata* in shady woods in the limestone districts of the north of England. The other kinds comprised in the group include *H. dumetorum* and *laxus* with green-flowers, *H. inter-*

The Green Hellebore in the Wild Garden.

medius, *graveolens*, and *purpurascens* with purplish blossoms, *H. Boconii* with much divided leaves, and *H. cyclophyllus* not at present in cultivation. W.

SPRING-FLOWERING BULBS.

THERE is a freshness and vigour in the growth of all bulbous-rooted plants which pre-eminently distinguish them from the generality of flowering plants. Not only are they exquisitely beautiful in themselves, varied in manner of growth with flowers of the most tender and delicate hues, but many of them emit an agreeable odour. When one sees the Snowdrop and Daffodil making their way through the earth, one knows that the dreary winter is over, and that each succeeding day will bring us something of a cheering nature; and no kind of flowering plant can give a greater amount of pleasure for time expended than such spring-flowering bulbs as the Hyacinth, Narcissus, Tulip, &c. Their culture is so simple, either as pot plants or in the open air, and the amount of time occupied in their growth is so small, that it lies in the power of nearly everyone to gratify their love for these beautiful and fragrant flowers. The handsomest of all spring-flowering bulbs, the Hyacinth, is within the reach of all, as mixed varieties of it may be purchased at a very cheap rate. Those who may not object to expense will of course choose named kinds, at a higher rate; but where the florist's ideal is not sought for, the cheaper

varieties will prove quite as satisfactory. Flowering bulbs associate well with all kinds of plants; for room decoration nothing excels them, as they harmonise beautifully with Ferns and other fine-foliated plants; and a few Hyacinths and Narcissi in the conservatory or winter garden impart a spring-like appearance thereto, such as is scarcely to be obtained by the use of any other flowering plants. In the winter garden there should always be pockets left in the Mossy turf, in which the pots may be plunged so as quite to hide them; in such positions bulbs have a most natural appearance, and remind one most vividly of those woodland scenes where Bluebells and Daffodils grow. In a large winter garden in Germany bulbs of all kinds were extensively employed in this manner. Recesses and nooks were left here and there amongst the evergreen trees and shrubs, and these were filled with flowering plants. The walks were bordered with *Selaginella*, and provision having been made for that purpose, bulbous and other flowering plants were so placed that they appeared to be springing up from the turf and amongst the shrubs in a most natural manner. This arrangement suited flowering plants generally very well; but the bulbs alone conveyed the impression that they might have been planted and grown into bloom there. In the arrangement of bouquets the bells of the Hyacinth are invaluable, the shades of blue being very effective. Tulips are not so highly valued as in former times, and by many are stigmatised as gaudy; but the scarlet *Van Thol* is very acceptable early in the year, being bright and distinct, and I certainly must confess to a large share of admiration for those grand varieties, the yellow *Tournesol* and *Rex Rubrorum*. They need the companionship of light, feathery foliage, and never appear to so much advantage as when associated with Maidenhair and other Ferns. They should, indeed, never be so placed that the eye rests upon them in their entirety, as the foliage is not in proportion to the size of the flowers, which renders them somewhat glaring and obtrusive. In Covent Garden Market they are often seen planted with small Ferns and Mosses, and this arrangement is probably the most tasteful that can be adopted. In the open air they have a more natural and pleasing appearance when growing near shrubs; they do not look well massed in beds in open situations—indeed, to my mind, this is not the place for any kind of bulb, their organisation plainly indicating that they need the fostering care of a more robust vegetation. I am not now writing from the florists' point of view, as I am aware that where a choice collection of Tulips is maintained, the grower so manages that his beds are in some way sheltered. I am merely alluding to the planting of the more common kinds with a view to their successful growth, without any special care being needed at blooming time; and this desideratum is best realised by choosing sites naturally congenial to them. As an instance, let us take the Daffodil. Where does it really appear most at home, and flower in the best manner? Not growing out of the bare earth in exposed situations, but springing from the fresh, bright turf, and where the heavy rains and furious winds are broken from them. I know a wood where the Daffodil and Primrose grow in the wildest profusion. Luxuriant masses of foliage spring up through the Grass and Mossy turf, and are covered with thousands of blooms. At flowering time it is indeed a scene of picturesque floral beauty, and is a point of pilgrimage for flower lovers, who carry off cartloads of them. Such scenes as this make one wish that our choicer kinds of Narcissi could be so placed that they might enjoy the conditions natural to them, and open up visions of what might be, but of what, alas! one can scarcely hope to see realised. It is however, very certain that more might be accomplished in this way than has been generally attempted not on a large scale perhaps; but there are few places where some portion of the garden could not be dedicated to this purpose. It is not so much the extent as the arrangement which charms, and in this matter we must, as far as possible, follow Nature's teachings. The modest little Snowdrop and the wild Hyacinth are always found peeping out from the midst of Grassy verdure; there would be something incongruous in their appearance if seen growing in the bare earth. Their home is where they are in constant association with other forms of vegetable life, and their near relatives will, I imagine, be found to thrive best when similarly situated. J. CORNHILL.

Byfleet.

PAMPAS GRASS IN AVENUES.

I HAVE often seen and admired the fine rows of Pampas Grass in the Messrs. Suttons' seed grounds, and have wondered that this truly noble plant has not ere now been largely used to decorate the approaches and drives to some of our large mansions. I should, however, undoubtedly object to the use of the Pampas Grass alone for this purpose, just as I object to the use of any one kind of tree for the formation of an avenue, except where it is desired to secure an arched umbrageous cover, and then nothing will excel a double row of the Elm, Lime, or Horse Chestnut. But lines of trees thus formed are, however pleasing when fully grown, the reverse of artistic and, indeed, planted with a rod and line, may be performed by any ordinary labourer. The Pampas Grass can only be introduced with effect where it is intended to obtain some fine display of planting skill and the production of a bold and broad outline. To obtain this a straight line of road should be avoided as, however, striking a straight avenue of trees may be, as is the case in the Long Walk at Windsor, for instance, it would be stiff, formal, and monotonous if found where a finely-planted border was intended rather than an avenue. Given a broad, well-kept carriage way, there should be on either side a clear margin of at least 10 ft. of Grass, at which line might be planted on either side rows of Pampas Grass. Not less than 30 ft. distant from these again on either side might come a row of fine Conifers, not limited to one kind, but composed of Wellingtonias, Decidars, Picea nobilis, P. Nordmanniana, and similar strong-growing kinds. They should be planted equally behind the Pampas Grass, and, midway between the clumps of Grass, but thrown back to form a separate line, should be planted good specimens of Cupressus Lawsoniana. Finally, on either side behind all, a row of Horse Chestnut or Elm, beneath which should run footways for pedestrians. This combination would be something worth looking at.

A. D.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Hardiness of *Stobæa purpurea*.—It may interest Mr. Hemley to know that *Stobæa purpurea* has proved perfectly hardy here for four years. It increases considerably by running underground shoots which push up in the spring. I have only the pale purple variety, and never saw a plant with flowers of so deep a colour as those represented by the plate in THE GARDEN a few weeks ago. It is to be regretted that some of our enterprising collectors do not introduce the other known species of *Stobæa* and *Berkheya*. They would, in all probability, be perfectly hardy, and are so curious that many would be glad to grow them. *S. purpurea* has never yet ripened seed here.—H. HARPER CREWE, Drayton-Beauchamp Rectory, Tring.

The Recent Lily Discussion.—Now and then some horticultural writer hits upon a subject of such universal interest that he is at once attacked and defended from a dozen directions, and, if he stands by his guns, will inevitably have his hands full. A few months of rather lively cut and parry usually brings a vast fund of dormant information to light and clears the atmosphere wonderfully. Our English friends are quite apt to do this sort of thing, and we notice that "Dunedin," Mr. T. Baines, and others have recently been discussing the treatment of Lilies in the columns of THE GARDEN. "Dunedin" believes in moving Lilies as soon as the flowers have faded, and he objects to encouraging the growth of stem roots. We differ from this portion of his treatment, although we agree as regards the decay of the old bulbs and the formation of new ones internally. We think that, with us, if fine Japan Lilies are desired, some top dressing and good mulching are necessary. We would move Lilies early in November, the stem being then withered. As an example of this treatment, we last season had *L. aratum* with forty-one perfect blossoms and *L. speciosum* with sixty, both being grown in the open ground.—"Californian Horticulturist."

Hollyhocks from Seed.—For decorative purposes, seedling Hollyhocks from a good collection are almost equal to named kinds, and there is, as a rule, more vigour about seedling plants than about established ones, and they are less liable to fall a prey to that terrible fungoid disease that has done so much injury to Hollyhocks in some districts. If the seeds be sown immediately in a warm house or a hotbed, and the young plants potted off and well attended to afterwards, most of them will flower this year. Strictly speaking, Hollyhocks are biennials under ordinary cultivation in the open air; but by sowing early in the year, and growing them on liberally with heat and plenty of moisture till the end of March, and hardening them off and planting them out in April, they will be converted into annuals. Some of them will probably be later in flowering, and it is possible that one or two may miss flowering; but nearly the whole will flower

well, and continue blooming till quite late in the season, most likely till cut off by frost. In order to have fine spikes, the soil should be deep and rich, and should have been well loosened up and manured some time previous to planting. Unless this has been well done, make large holes where each is to be planted, and put in each hole half a bushel of rotten turf and manure in equal parts and plant in it. This will be a good plan to adopt when planting among shrubs, or in any position where it is not convenient to trench the ground.—E. H.

PLANT CULTURE FOR MARKET.

MIGNONETTE.—Growers for market cultivate Mignonette to perfection, and at every season of the year there is a demand for it both in pots and in a cut state. In spring plants in pots are sent plentifully to market. These are obtained from seed sown in 5-in. or 6-in. pots in autumn; when large enough to handle, the young plants are thinned out, leaving eight or nine of the strongest in each pot. These are then kept in brick pits close to the glass, are allowed abundance of air, and are protected during severe weather by mats or straw. In the month of March I have seen in one place 1750 dozen potfuls of Mignonette all coming into flower at one time, and an equal quantity of spring-sown plants growing on to succeed them. Well-grown Mignonette fetches early in spring from 7s. to 10s. per dozen pots. Mignonette as grown for market is of a very different description to that usually grown in private gardens; the plants are dwarf, requiring little or no staking; the leaves are large and of a black-green colour, and the columnar spikes of blossoms are well-formed, erect, and of large size. The bank of Mignonette shown by Mr. Reeves, of Acton, at the great exhibition of Covent Garden produce held at South Kensington on May 2, 1877, will probably be long remembered by those who saw it. Some sow their Mignonette intended to supply cut bloom in larger pots than those described, and small growers assert that early in spring they get on some occasions almost as much money for a basket of Mignonette sprays as they do for a load of common market plants. The soil used for Mignonette is of a light rich character; the pots are not filled at the time of sowing, but a margin is left for earthing up with rotted manure when the plants are well up above the pot. As regards staking, when the plants require any, two or three small sticks are placed round the edge of the pots, and a piece of bast is run carelessly round them. Damp is the greatest enemy to Mignonette in winter and spring, and this can only be guarded against by watering on fine days, leaving off the lights until the foliage has become dry, and by at all times giving all the air possible when the weather is favourable.

THE HYDRANGEA.—Few flowering plants which are brought to market are held in higher estimation than Hydrangeas, and nearly all London florists grow them largely. Their huge heads of rosy-coloured blossoms last for a considerable time, even when placed in dark, dusty rooms, provided the roots of the plants receive plenty of water. Hydrangeas are struck from cuttings usually obtained from old plants growing in the open ground, with which most places are furnished. They are inserted in autumn, winter, and spring, and, during the time they are leafless, they are packed closely together under stages or other out-of-the-way places until they again start into growth, when they must have air, light, and water if healthy, green foliage and large heads of bloom be desired. One of the best growers of the Hydrangea is Mr. Plimley, of Acton. His plants are flowered in from twelve to fifteen months, each plant bearing from one to three magnificent heads of bloom. The largest plants, which have

several shoots, are those struck from cuttings in the autumn, and which have been stopped. Those that we see in the market with a single stem surmounted by one immense head of bloom are the produce of cuttings struck during the winter and spring. The soil used for *Hydrangeas* is good loam, to which are added some well-rotted manure and sand. Those plants which are required to produce blue flowers are either grown in soil mixed with steel filings or they are watered with water in which steel filings have been steeped. The white-flowered *Hydrangea* Thomas Hogg, figured the other day in *THE GARDEN*, will, when better known, doubtless become a fine market plant.

CINERARIAS.—These are grown by thousands for market—sturdy, dwarf plants in 5-in. pots. They are raised from seed sown in spring, and the young plants are potted on in good rich loam until they occupy 6-in. pots. In autumn they are placed in the houses, and when they come into bloom the best are selected and moved to low, span-roofed pits for seeding purposes; the rest are taken to market. Those intended for seed producers are placed in sections according to their colours, and every possible precaution is taken to prevent cross-fertilisation. Abundance of air is admitted to the plants whilst they are seeding, and their roots are kept regularly supplied with water. As fast as the seeds ripen, they are gathered, and should any fall to the ground (which is covered with ashes) they quickly germinate and go a long way towards furnishing a supply of plants for the next years' blooming. Self or well-defined colours, such as blue, purple, and rose, or white kinds edged with these colours, are most sought after, and there is also a strain with mauve flowers which is much in demand; the plants should be dwarf in habit, and the flowers should have large and smooth petals. One grower in the north of London has six or eight lean-to houses, in which are erected stair-like stages within 2 ft. or 3 ft. of the glass. These are filled with *Cinerarias* in full bloom from soon after Christmas until after Easter.

HELIOTROPES.—Both for supplying cut bloom and in the form of flowering plants, the *Heliotrope* is grown largely for market. Cuttings of it from stock plants are put in at nearly all seasons of the year. The plants are grown in loam and leaf-mould, and the shoots are kept constantly stopped in order to keep them dwarf and bushy. In June and July the bulk of the pot plants come into market, but they may be had nearly every month in the year. Dark-flowered kinds are those mostly grown, and such as possess a very dwarf, compact habit, with every shoot bearing a good truss of sweet-scented blossoms. Mr. Hayes, of Edmonton, has a whole house devoted to *Heliotropes* for furnishing cut bloom. The plants, which are very old, were formerly in pots; but, when, after a time, it became necessary to give them more root-room, they were so large that the operation became a difficult one; the pots which they occupied were, therefore, broken up and the balls of roots were firmly surrounded with good soil—thus practically planting them out. In this position these plants have been growing for about twenty-five years, and have formed a dense bank from 3 ft. to 10 ft. high, and from 9 ft. to 10 ft. through, and 50 ft. in length. From these plants abundance of sweet-scented blossoms can be cut at all seasons of the year, and during the winter months are especially valuable, all the attention which the plants require being a good watering occasionally during hot weather and removing decayed leaves. The blooms are cut several times a week all the year round and sent to market.

CYTISUS RACEMOSUS.—This makes a capital market plant, but it is rather difficult to propagate except from seed, and

plants obtained in that way are by no means equal to those raised from cuttings. *Cytisuses* are largely grown by fruit growers, who place them under their Vines whilst the latter are at rest, a position for which *Cytisuses* are well adapted, inasmuch as their season of flowering commences before the Vines have made so much growth as to injure them by their shade, and, by filling all the Vineries with them, as the Vines are started in succession, they bloom in regular order. These *Cytisuses* are struck from cuttings inserted in 6-in. pots in the autumn, from forty to fifty being placed in each pot, and placed in a close but unheated house. They make very little growth until the following spring; then, when they commence to grow, they are potted off singly into 4-in. pots, and placed in a warm house until the weather will permit them to be placed out-of-doors; during summer they are shifted into 6-in. pots, and by next spring they make handsome, bushy plants from 12 in. to 15 in. high, and nearly as much through, furnished with long spikes of bright golden blossoms, and dark green, healthy foliage down to the very rims of the pots.

RHODANTHES.—These handsome everlastings are extensively cultivated for market; one grower, indeed, disposes of from 10,000 to 15,000 potfuls of them yearly. The seed, which is imported direct from Belgium, is sown in successive batches in shallow wooden boxes. These are placed in gentle heat until the young plants make their appearance, when they are immediately removed to a lighter and cooler atmosphere, and, as they advance in growth, air is admitted freely to them on every favourable opportunity. When large enough to handle they are pricked off into 5-in. or 6-in. pots, putting from five to seven plants in each. They are then placed in light, airy positions on the floors of the houses, where they remain until they come into flower, when they are at once sent to market and replaced by others in less advanced stages of growth. Sowing usually commences early in February, and continues until the end of April or beginning of May, and from this latter period onward through the summer a succession of bushy, well-flowered plants is maintained. The varieties grown are *R. Manglesi*, and *R. maculata* and *alba*.

STOKESIA CYANEA.—This furnishes the chief supply of blue flowers for bouquet making during the autumn. They first make their appearance early in September, and are constantly to be seen in the florists' shops until late in December. The blue, Aster-like flowers are large and showy, each measuring about 3½ in. in diameter, and apparently semi-double. In the late-blooming property of this plant consists its chief value, for blue flowers are at this season of the year comparatively scarce. The plants are increased by division in the spring; and the slips, after being taken off, are inserted in a warm border or frame a few inches apart, in sharp, sandy soil. As soon as they are well rooted they are transplanted into good soil, and in August are lifted and potted, and when cold weather sets in are afforded the protection of a frame. I have never yet seen this plant offered for sale in pots; probably because its habit of growth is not sufficiently dwarf and stocky.

THE FORGET-ME-NOT.—In a cut state, flowers of this find a ready sale. They are associated with the choicest of white flowers in bouquets, and few blue flowers are prettier or more effective. Sometimes a few sprays surround a Tea Rose in a button-hole bouquet, and handfuls of *Forget-me-nots* are often sold in the streets at a very cheap rate. Plants of this universal favourite in pots also meet with a ready sale; they are usually taken from the ground when

in bloom, and potted the night before they are brought to market. There are many different kinds of Forget-me-not, but the common type is the one generally found in the market. All of them are easily raised from seed or cuttings, but sowing seed is the only practical mode of acquiring a stock of most of them. If sown in August, the plants will flower the next summer; and, if sown in spring, they will flower late in the autumn or winter. The seed may be sown thinly in the open air or in pans or pots, and, being remarkably small, it can hardly be covered too lightly. As soon as the young plants are large enough to handle, they are pricked off in a border out-of-doors or potted singly in 2½-in. pots. If placed in a cold frame for a time, they make rapid progress, and soon form useful little plants. Shift as they require it; and almost any of the Forget-me-nots grow into excellent window or room plants in 4-in. or 6-in. pots. The best place in which to grow the Forget-me-nots until they reach their flowering stage, is a partially-shaded, sheltered situation out-of-doors. They grow well in a mixture of rotten leaf-mould, manure, and sand. Good drainage is necessary, as most of these Forget-me-nots are semi-alpine plants, and cannot endure stagnant water at the roots, though they must not be allowed to get dry. Plants potted from the open ground in October or November, and, placed in a temperature of 50°, will flower at Christmas, and a succession may easily be had in bloom indoors till March, at which season it bursts into full beauty in the open air. Such fine Forget-me-nots as *Myosotis Impératrice Elizabeth*, *M. azorica coelestina*, *M. semperflorens*, *M. sylvatica*, *M. alpestris nana* *corulea* and its white variety, are all good kinds; but, for pot culture, *M. dissitiflora* is perhaps the best of all. The colour, when the blossoms are fully expanded, is a most exquisite blue, and the plant is good in habit. It grows to a height of about 6 in., and spreads out freely, soon furnishing a 4-in. or 6-in. pot. *M. azorica coelestina*, an improved variety of a well-known rich dark blue Forget-me-not, is also a plant of great beauty. *M. semperflorens* is a hardy variety that continues flowering with little trouble from spring to autumn. The white and blue dwarf Forget-me-nots (*M. alpestris nana*) only grow about 4 in. in height, and are little gems for pot culture.

LILIES.—These are principally sold in pots, their flowers being too large for anything, except for church or similar decorations, and, as a rule, flowers are not much in demand for such purposes when the majority of Lilies are in bloom. The earliest kinds are *L. candidum*, *L. eximium* and *L. longiflorum*, all of which are in bloom in June and July, and these are followed by *L. auratum*, and the white and rose varieties of *L. speciosum*. Lilies are sometimes grown in the open ground, and lifted and potted just before they come into flower; but, for early flowering, the bulbs are potted in autumn in 6-in. or 8-in. pots, filled three parts full of soil, and plunged in cold pits or placed on the stages of cool houses, where abundance of air and light can be afforded them. The soil used is rich, fibrous loam, rotted cow manure, and leaf-mould, with which a few lumps of peat are mixed if the loam be not so full of fibre as could be desired. Little or no water is given until the shoots make their appearance, after which the soil is kept well moistened. When it is getting full of roots, and these can be seen issuing from the stems of the plants, the pots are filled up with loam and manure. No more heat is given beyond just enough to keep the plants healthy and free from damp until the bloom-buds show themselves, when the plants are subjected to a little heat and kept syringed overhead to bring out

the bloom. *L. undulatum* is grown in quantity. It comes into flower early, but is not so much in demand as other kinds on account of the colour of its flowers. Potfuls of it may, however, be seen in abundance during May and June. Of other kinds there are generally two or three stems in a pot, and sometimes eight or nine in large pots. Lilies for market are much dwarfer than those usually seen in private gardens. This is effected by keeping them close to the glass, admitting plenty of air and keeping them well supplied with water whilst growing.

I have now named the bulk of indoor flowering plants grown for market; but there are many more cultivated to a less extent. Among these may be mentioned:

KALOSANTHES COCCINEA, a showy plant, and one which meets with a ready sale. It cannot, however, be grown so cheaply as many others, on account of its taking a comparatively long time to come into flower. Cuttings of it from old, cut-back plants as early in summer as they can be got, struck in gentle heat, and afterwards potted, either singly in 4-in. pots or four or five together in a 5-in. or 6-in. one. They are exposed to plenty of air, light, and sunshine in order that their wood may become stiff and firm, and next spring they flower. Plants of it potted singly, of course, only bear one head of bloom, and are, therefore, not sent to market; but sometimes these cuttings have two shoots and, in that case, two heads of bloom, and these are sent to market, but the plants with single shoots are cut back to within 6-in. or so of the pot, when they emit four or five shoots, which flower well the next season.

ABUTILONS are likewise grown for supplying cut flowers, and the white one, *A. Boule de Nieve*, is in great request as a pot plant. Most of them, however, grow too lanky for market work, and they are consequently not much grown in this way. A dwarf variegated kind named *A. Darwini tessellatum*, however, has been taken in hand by some growers for market, who find that good, bushy plants of it can be produced in a very short time by stopping the points of the shoots, and, as it flowers more freely than any other kind during winter, it will, no doubt, ere long become a good market plant. C. W. S.

Tuberose.—The strong sweet fragrance of the flowers of these is not surpassed even by that of the *Gardenia*; indeed, it is much more agreeable, as Tuberose have not that sickly odour about them which the *Gardenia* gives off when one comes too near it. Besides, the flowers are quite as beautiful, last longer, and can be used for similar purposes; and last but not least, the plants are easily grown, and are not troubled with insects. The imported roots are the best, and should be potted as soon as possible, at least for early work. A noteworthy authority on the subject recommends the plants to be plunged in strong bottom heat as soon as potted, and afterwards grown on in cooler quarters; but they do quite as well if started gently and pushed on leisurely. One lot was potted last year in February, rather late in the month, and started in an intermediate house, but the pots were not plunged. The plants started into growth sooner than was expected, and, to prevent the leaves and stems from becoming soft and lanky, they were moved into another house, where they got plenty of light and air, and a place for themselves; and throughout the summer and part of the autumn no artificial heat given, but the house was kept warmer than a greenhouse. They made robust growth, but very tall stems, and did not flower till August, and they continued to produce flowers for about three months. Later in the autumn a little heat was given, to assist the development of the flowers. As it was just the season we need such flowers, most single flowers were out every day for the house, and a number of the plants were placed in the conservatory to give fragrance to the house. The Tuberose is best grown in single plants to a pot, and 6-in. pots are a suitable size. A compost consisting of three parts loam, one part peat and sand, and a little well-rotted manure, will suit well. Good drainage, but not too much of it, should be afforded, and during growth plenty of water should be given. S. W.

NEW OR RARE PLANTS.

FRITILLARIA KARELINI.

This beautiful little Fritillary, although new to the present generation, was in cultivation in this country upwards of forty years ago, and was depicted in Sweet's "British Flower Garden," series ii., plate 283. It was originally sent to Mr. Anderson, of the Chelsea Botanic Gardens, in 1836, by Dr. Fischer, of St. Petersburg. The accompanying engraving is half the natural size of the plant, and was reduced from a coloured figure which appeared in the "Botanical Magazine" for January of the current year. In the colour of its flowers it exhibits a little variation, as shown by the different figures

Fritillaria Karelini.

of it published. The variety represented in the "Botanical Magazine," grown by Mr. George Maw, of Broseley, has white flowers suffused with pink and spotted with red. It has a wide range of distribution in Central Asia, extending from the Ural and Altai Mountains, through Turkestan to Afghanistan, Beloochistan, and Persia, and it flowers with us in winter. On account of a slight difference in the process at the base of the petals, it was formerly separated from Fritillaria under the distinctive name of *Rhinopetalum*, literally horse petal, and it was under this name that it was cultivated on its first introduction. The re-introduction of this lovely plant into European gardens is due, I believe, to the late Mr. Fedenschow, one of the many recent Russian explorers of Central Asia.

W. B. HEMSLEY.

HOTBEDS AND THEIR USES.

THE heat generated by the fermentation of leaves, stable manure, and other waste vegetable and animal substances, is, when under proper control, so genial and stimulating and, withal, so cheap, costing little in most country places beyond the labour of collecting and working up, that it forms the most economical mode of forcing all crops that require only a few weeks or months for their production; and, when exhausted, the materials are still available for manure, and when a proper place is assigned for them there need be no litter or

untidiness. January and February are the months during which hotbed making begins in earnest, and if a large heap of fermenting materials be ready for use through the spring the production of many crops besides Cucumbers, Melons, and Potatoes, may be made more certain and simple. In preparing for hotbed making the first thing of course is to collect and cart together the materials, and, so far as regards the leaves, these should all have been brought together before Christmas. All ours were collected just before the frost set in, and we carted them home during the time the first storm lasted; there was a little snow mixed with some of them, but not more than sufficient to make them heat well when thrown into a heap. Leaves alone, when in sufficient bulk, will force all kinds of vegetables, but it is always best to mix a proportion of stable manure with them; about half of each is a good proportion. The leaves neutralise and absorb the fiery gases of the manure, and the latter, on the other hand, communicates some of its heating power to the leaves, so that a hotbed made up of the two is better in every respect than when either is used alone, no matter how previously well prepared, either by mixing or turning. When all the materials are collected together, the manure and leaves should be well shaken up and mixed in the right proportions. If, as sometimes happens, there are dry spots in the heap, these should be watered, as there must be a certain amount of moisture present to insure fermentation. When the heap has lain ten days or a fortnight it should be turned over and well shaken together again, throwing the outsides of the heap into the middle and watering any further dry spots, so that a regular, even state of moisture exists throughout. Early Cucumbers or Melons, if grown in hotbeds, will require the most attention and the greatest nicety in the preparation of the materials and the proper bulk of the beds.

Cucumbers started in February should have the beds at least 3 ft. longer and wider than the frames—i.e., they should project beyond the frame 15 in. on all sides. The bed should be 5½ ft. high at the back, and 4 ft. high at the front; this will give it a good pitch to the sun. It should be put together carefully, and of the same substance and firmness throughout, so that the heat may be regular and steady. If made too solid the heat will be sluggish, and if left too open the heat will, perhaps, be too great. There must be a certain amount of air mixed with the material to insure steady fermentation, and, if that amount be exceeded or curtailed, the result will not be so good, and it is here that a little practical knowledge becomes useful, as something depends upon the condition of the materials as to the amount of pressure that ought to be applied. Very often a bed may be put up, and will answer admirably without any treading at all, the workmen simply beating it down with their forks as they build it up. In other cases this will not make it firm enough, and the workmen have to get on it and tread it moderately firm. In many cases some shelter should be applied to hotbeds. A row of bundles of Pea sticks set up endways on the windward side has a wonderful effect in keeping the heat steady during boisterous weather. Shutters reared up against the bed on the windy side will also answer the same purpose; anything, in short, that will furnish shelter. Hotbeds for forcing Potatoes, Carrots, French Beans, and other vegetables, will not require so much preparation, and need not be so large as those for Cucumbers, and, if placed in front of and close to the Cucumber and Melon beds, leaving plenty of space between the rows of frames to get between them, they will answer the purpose of linings to the latter, and it will be, in fact, altogether an economical arrangement. I have tried this plan often, and found it very advantageous, as the space between the rows of frames could be filled up almost as high as the top in cold weather. I have occasionally, when I had much forcing to do, had as many as three and four rows of frames all ranged closely together in parallel lines, and the heat in such a bulk of material is always regular and steady, and not nearly so much labour is required. The frames in the centre row would be occupied with Cucumbers and Melons, and the outside rows with Potatoes, Beans, Carrots, &c.

As the season advances, a good deal of forcing can be done with only a limited quantity of material. Digging a hole in a sheltered corner 2 ft. deep, and filling it full of hot litter and leaves, returning 6 in.

or 8 in. of the mellowest, driest soil, will make a capital bed for early Radishes, Early Horn Carrots, White Dutch Turnips, or raising young Onions, Leeks, or other plants for transplanting which may be desired early. Take the case of early Long-pod Beans; if planted thickly on such a bed in a sheltered place, when the weather becomes more settled they can be moved to a more open situation, and nothing transplants better. Any plant that transplants easily—and almost all will do so, if pains be taken with them—may gain a week in point of time by being started on one of these open-air hotbeds without any glass at all. Mats or netting, or even evergreen branches, or a little straw may be used to cover and protect the beds in cold weather. Cabbages, Lettuces, Cauliflowers, and Brussels Sprouts may be sown early in February on such a bed in small quantities, in order to have a few plants to put out early, or to fill up vacancies caused by the severe winter. In some places there will be a scarcity of green vegetables, and an effort should be made to push forward crops to fill up blanks as early as possible.

Later in the season hotbeds of a temporary character are exceedingly valuable for purposes of propagation, such as the rooting of cuttings or raising seeds. Lobelias, Alternantheras, Iresines, Coleuses, and similar plants may be raised on slight hotbeds in April, dibbled into a thin stratum of light sandy soil on the top of the fermenting materials. Having a good many thousands of plants to provide annually, I have tried many different plans, in order to discover the best and cheapest way of raising them, and which will at the same time give the best results, and I have finally adopted this for spring propagation. It necessitates a good stock being kept, but where many plants are required this should be done always, as although, by severe forcing and pushing, a large number of young plants may be obtained from a limited number of stock plants, yet the produce from plants over forced is never so strong or vigorous as those treated more naturally, and beds planted with weakly plants are a long time in filling up, and never grow up together regularly. An ordinary two-light frame placed on a bed of fermenting materials 3 ft. deep at back and 2 ft. deep at front, say in the middle of April, will hold easily 2,000 Lobelias or other small cuttings. The warmth from such a bed will be just sufficient to root the cuttings and then decline. Healthy cuttings of most plants in such a genial bed will strike in a week, and at that season, if more stock be required, the tops may soon be taken off and dibbled into another bed of similar size, and, as soon as the cuttings are fairly rooted, abundance of air can be given, until finally the lights can be removed altogether. Although I have mentioned the middle of April, yet of course everything depends upon the work to be done and the conveniences for doing it; yet I may say that the best and most lasting beds of Lobelias which we had last year were from cuttings inserted in a very slight hotbed the last week in April. To be able to grow these plants in frames in spring without a single pot relieves the houses, and also the hands, a very great deal, and there is no loss as regards efficiency; on the contrary, in that respect there is an improvement.

E. HOBDAY.

Garden Labels.—The best with which I am acquainted are those manufactured by Mr. Smith, of Stratford-on-Avon, who has recently made great improvements in labels—notably in those for Roses—by having them neatly soldered to the wire support. By this method there is not the least danger of the label getting displaced by the wind. The names are in the form of raised letters, and the label is capable of withstanding any atmospheric action to which it may be subjected, for a great many years.—A. HOSSACK.

Nettles.—Notwithstanding the surprise expressed by the Rev. Mr. Harpur Crewe (p. 4) at M. Levallois's statement regarding the co-relation between the Nettle and the abodes of man, it is a belief with which I have long been familiar, although whether it is a vulgar error or not I am unable to say. The following fact, however, lends some support to the popular idea. Some four or five years ago I came upon an isolated patch of Nettles, when grouse-shooting on a Scotch moor some six miles distant from the nearest human habitation. Here, thought I, is a proof of the fallacy of the received opinion, but on inquiry I found that a shepherd's hut had once stood on the spot, all signs of which had long since disappeared.—W. E. HAWKES.

PLATE CIXVI.

THE YELLOW TORENIA.

(TORENIA BAILLONI).

MANY of our readers who attend the meetings of the Royal Horticultural Society will remember this pretty *Torenia*, which has been exhibited several times by Messrs. Veitch. We have only seen small plants of it, but in habit, foliage, and flowers, except in the colour of the latter, it is essentially *T. asiatica*, of which it is probably a variety, though a very distinct one. In the colouration of the flowers, it reminds us of one of the varieties of *Thunbergia alata*, the lobes of the corolla being of a rich golden-yellow, whilst the tube and throat are of a deep reddish-purple. Like *T. asiatica* and *Fournieri*, it is easily grown, the conditions requisite for the successful cultivation of either suiting this also. Although it will grow in a cool greenhouse, and probably (like *T. Fournieri*) even flower freely in warm, sheltered, sunny spots in our southern counties, it is most at home in a warm house, where, if it meets with anything like generous treatment, it will flower the greater part of the year. Like *T. asiatica* it makes a good basket plant, and in this respect possesses a decided advantage over *T. Fournieri*, which is of more bushy upright growth. *T. Bailloni* seems to do best in a light, well-drained compost consisting of one-half fibrous peat and the other half loam and leaf mould; though not strictly an annual it is best to treat it as such, and a stock of it is easily and quickly raised from seeds, to obtain which, however, artificial fertilisation must frequently be resorted to. To M. Godefroy-Lebeuf, of Argenteuil, near Paris, belongs the honour of introducing this lovely plant to European gardens. It is a native of Cochinchina.

PLANTS AFFECTED BY FROST AND EAST WIND IN THE RIVIERA.

I SUPPLEMENT my notice (p. 59) of the effects of frost during the winter in the Riviera by a list of plants that have suffered the most from exposure. The list was furnished to me by Messrs. Piv & Gullino, nurserymen, of San Remo, and may be relied on as authentic. I give the list alphabetically for the sake of easy reference, irrespective of class or country:—

<i>Acacia corymbosa</i>	<i>Hebeclinium lanthnum</i>
<i>falcat</i>	<i>atro-rubens</i>
<i>Achania Malaviscus</i>	<i>Hoya carnea</i>
<i>Achyranthes picta</i>	<i>Ichroma tabulosum</i>
<i>Aralia papyrifera</i>	<i>Warscewiczii</i>
<i>Begonia dodealea</i>	<i>Iresine Lindenii</i>
<i>Cereus truncatus</i>	<i>Jacaranda mimosæfolia</i>
<i>Cestrum aurantiacum</i>	<i>Justicia rosea</i>
<i>Gilanthus magnificus</i>	<i>Libonia floribunda</i>
<i>Cobaea scandens</i>	<i>Lippia montevidensis</i>
<i>Cuphea emiens</i>	<i>Lophospermum scandens</i>
<i>Cyrtanthera magnifica</i>	<i>Musa paradisiaca</i>
<i>Dahlia imperialis</i>	<i>Pereskia aculeata</i>
<i>Datura arborea</i>	<i>Salvia involucrella</i>
<i>Echium giganteum</i>	<i>Sparmannia africana</i>
<i>caudicans</i>	<i>Sphaeralcea umbellata</i>
<i>Geranium hederæfolium</i>	<i>Tradescantia discolor</i>
<i>Goldfussia Dicksoni</i>	<i>Wigandia caracasana</i>

Hovingham Lodge, York.

PETER INCHBALD.

Eupatorium odoratissimum.—This is a very useful plant for winter blooming. It is invaluable for the cool conservatory, and is especially suitable where means are limited. We have a number of large bushes of it standing in a house where the frost has only just been kept out, quite white with large panicles of flowers; and they have been in this condition for the last six weeks, and will continue so for a long time yet, and after the first bloom is over, if the ends of the shoots are cut off, a new crop of flowers will be produced. The plants to which I am referring were old ones cut back last June, planted out in an open sunny border, lifted and potted in September, placed on the north side of a fence to get established a little, and housed before sharp frost was expected. Cuttings struck in spring and planted out will make good-sized bushes in one season, but do not, of course, make such dense, well furnished specimens as older plants that have been well pruned in and planted out about June.—E. H.

PROPAGATING.

PERNETTIA MUCRONATA.—This beautiful American flowering and fruiting shrub may be increased by means of cuttings, prepared as shown in the accompanying woodcut, and inserted in April and May. The soil, which should consist of equal parts yellow loam and peat, and a fair sprinkling of silver sand should be well mixed together and sifted somewhat finely. Select a spot on a sunny border, place thereon handglasses or a small frame, and fill them with the soil just mentioned to the depth of 4 in. or 5 in., pressing it down rather firmly. Then put a little sand on the top, give a slight sprinkling of water, and insert the cuttings, fixing them in firmly. Then give a good watering to settle them in their places, and cover them up, keeping them close for the first three weeks till they begin to callus, when the glass top may be removed occasionally for an hour or two each morning if not frosty. They will be ready, if all has gone well, for potting off about the end of August. H. H.

Cutting of *Pernettya mucronata*.

SPRING PROPAGATION FROM SEED.

WHILE many kinds of bedding plants are propagated by means of cuttings in spring, many also are raised from seed, and the time has now arrived when such must have attention. Where there are only small quantities of plants wanted from seed, a pinch of such as *Lobelia*, *Pyrethrum*, &c., sown in a small box or 8-in. pot, will generally be sufficient, but where large numbers are wanted the best way of raising them is to sow the seeds on hotbeds. This is the plan which we mostly adopt, and it answers capitally. Some of the frames for our hotbeds are 8 ft. by 6 ft., while others are only half that size. The hotbeds, which consist of about equal parts of long manure and leaves, are built up firmly to 3 ft. high at the back and 2 ft. in front. On this the frame is placed, and then soil suitable to the requirements of the seed to be sown is spread all over the inside of the frame to a depth of 6 in. This is made firm and smooth on the surface, and then the seeds are sown, afterwards shaking a little soil over them through a fine sieve. One of the largest sized frames sown in this manner with *Lobelia*, *Pyrethrum*, *Stocks*, *Phlox Drummondii*, *Tagetes*, *Verbena venosa*, or similar bedding plants, contain many hundreds of seedlings, and when the seed is good and not sown too thickly the majority may be kept in the frame till bedding out time has arrived. Air is admitted by degrees as the plants grow and the weather becomes mild, and, in April, according to the weather, the lights may be taken off altogether. Those who have only one frame may sow many seeds in it, making a little patch of each. The seeds germinate much more freely treated in this way than in pots, where there is always danger of their becoming dry, and thereby being severely checked. The plants, too, grow much better, when young, in frames than in pots, and the labour saved in not having to shift them is great, not to speak of the space left vacant in other houses, owing to not having to accommodate such plants. We find a mixture of fine loam, old Mushroom manure, or leaf-mould, well decayed, with a little river sand, to be a good mixture in which to sow all kinds of small seeds, as the latter not only germinate freely in it, but the young plants grow well in it afterwards. In propagating by means of seeds, as many do, in pots, it is necessary that the pots should, in the first place, be well drained, and it is not good to use them smaller than 6 in. in diameter. When less than this the soil in them becomes so soon dry that the young seedlings may receive a check at any hour. Pans about 4 in. deep, and 1 ft. or more in width, are also used for seed sowing, and very useful they are for the purpose. Like pots, they must be well drained, and over the

drainage should be placed a layer of Moss, or some rough material, before filling in the soil. Rough material may be put at the bottom, but it is necessary that fine soil should be on the top in which the seed is sown. To prevent the soil from becoming quickly dry it should be pressed very firmly, and, in order to insure quick germination, the pots may be plunged in a slight bottom heat. Failing this, let them be set in a warm house, with the mouth of the pot covered over with a piece of glass. In sowing seeds in pots as the spring advances, it is a good plan to put a sheet of paper over the glass until the young plants are through the soil. Primulas are as much benefited by this as anything which we have tried. In raising plants from seed in small pots, it very often happens that they are allowed to grow into a close mass before they are thinned out or transplanted. This ruins many by drawing them up with long stems, and checks them severely when planted singly by themselves. To avoid this, and to secure sturdy young plants from the first, at least one-half of the young plants should be carefully drawn out as soon as they are large enough to be handled and planted at a suitable distance apart in pots, boxes, or frames. Fifty plants of this kind will be worth 200 close-grown ones at planting out time. All seeds from which flower garden plants are expected should be sown about the beginning of February. This also applies to *Stocks* and *Asters*, as these are very often sown too late to give them a fair chance of blooming fully before being cut off by frost in autumn. Early vegetables, as well as flower seeds may all be advantageously propagated in the same way. For *Cauliflowers*, *Celery*, *Leeks*, *Radishes*, *Carrots*, &c., nothing surpasses the hotbed and frame. When seedlings which have to be planted in the open ground are raised in pots, plant them on a hotbed as soon as they are large enough to handle, as they will grow more freely there than anywhere else; besides, when in a frame they are always near the glass; consequently, they can be grown dwarf, and as air can be freely admitted at any time or in any quantity, they may be planted out at any time desired. CAMBRIAN.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Brugmansias.—Where large greenhouses or conservatories exist, these stately, free-flowering subjects are most effective, few plants being more imposing than they are when well furnished with large trumpet-shaped flowers. In no way have they a better appearance than when grown as standards on stems 4 ft. or 5 ft. in height. Where there are plants of these, if not already of this shape, they can easily be trained to it by cutting the side branches away and reducing the head to the form required; if placed in a newly-started Vinery or Peach house, where they will get a moderate amount of warmth, they will break freely, after which they can be shaken out, repotted, and grown on preparatory to being turned out-of-doors for a time in the summer.

Clianthuses.—*C. Dampieri* is seldom seen, yet it is one of the most distinct and gorgeous greenhouse plants in existence, and no doubt would be more generally cultivated, were it not that it refuses to grow under the treatment with which the majority of other subjects succeed. Plants, raised from seed last summer, now in single pots, should have a good light position, with a temperature of 40° or 45° by night, to encourage both top and root growth, so that they may be in good condition early in spring for having one shift given them, a system by which alone I have found them to succeed well. *C. puniceus* and *C. magnificus*, which some growers prefer, unlike the first named, can be kept on for a number of years. Examples that bloomed last summer should now be cut back more or less according to the size they have attained, and that which it is deemed requisite to grow them to; if at the same time they are syringed freely with a solution of Gishurst, it will destroy any fugitive red spiders, or their eggs, that may happen to be upon them. It may, perhaps, not be generally known, that *C. magnificus* is one of the best and most distinct plants for cultivating in a window, if the simple precaution be taken of syringing it freely with clean water every week or ten days to keep it free from spider.

Mitrasia coccinea.—This handsome old-fashioned plant has much to recommend it, although never clothed so profusely with flowers as some of the more ordinarily grown subjects, yet the length of time that it produces its glowing mitre-shaped blooms, compen-

sates for want of profusion at any one time. It is equally adapted for either large or small houses. Plants that have flowered through the autumn, should now be cut back and kept a little close, so as to induce them to break previous to repotting; the young shoots, when a few inches long, will be suitable for propagation.

Swainsonas.—Where these are grown to clothe a pillar in a greenhouse, for which purpose they are well adapted, they should now have their branches shortened back at different heights to cause their breaking in a way that will furnish them with healthy young flowering shoots from the base upwards. When grown as trained pot specimens they will require cutting in a like manner.

Coronilla glauca.—Young plants of this struck from cuttings last year should, in common with other young stock of a similar character, be kept a few degrees warmer than an ordinary greenhouse, stopping the leading shoots to get them to break in a way that will secure a bushy habit. Where a few of such things as the above are grown they will give little more trouble than the more usually met with subjects, and they at once elevate the greenhouse above the level of simply being a receptacle for a few families of the commonest plants.

Hovea Celsi.—This most beautiful of Pea-blossomed subjects, with its unsurpassed purplish-blue flowers, is one of the very best plants for training on an end wall in a corner, or up a pillar of a greenhouse, where it can be left to assume its naturally erect habit without stopping or heading down. Young, healthy trade plants that have not been so long confined in the pots as to stunt the roots, if procured now, and kept for a few weeks in the greenhouse, will be in a condition for moving onwards. I may here remark that young, hardwooded plants, the propagation of which is ordinarily left to those who grow for sale, where required, should be got in without delay, as doing this before growth commences, will enable their being potted sufficiently early to permit of a full season's growth being made, by which means the breakage and injury to young, tender shoots, and also loss of time, are avoided.

Old Fuchsias.—Young plants of these are much more effective than old ones, unless the latter are very differently managed from the way they are mostly seen, for, in cutting back the old stems, the knife is frequently not used freely enough, whereby the young growth that is formed is with difficulty made to hide the old, bare wood. Another cause why old Fuchsias do not break in a manner to furnish them sufficiently, is the bad usage they often receive by thrusting them under stages, or in any out-of-the-way place, during the winter; such treatment, to prevent their keeping on growing, necessitates the total withholding of water, by which means all but a few of the thickest roots perish, the result being that when top growth commences there is not enough root power to support it. Plants that have been treated in this way, and which, through the absence of any young ones struck last summer, must needs be fallen back on, I should advise to be cut down much lower than they usually are, say to within 12 in. or less of the collar, placing them in a genial, growing temperature, but previous to that see that the soil is fairly moistened.

Fuchsias from Last Year's Struck Cuttings.—Where the course is followed of annually striking cuttings about August and keeping them growing on slowly through the winter, though they may not bloom quite so early as the old plants, yet they will be much fairer to look upon when they do flower; but there is one point in their cultivation not to be lost sight of, that is, they must always have more root room given them before they get pot-bound, as this has a direct tendency to induce a hard condition of the wood, which will have a greater disposition to bloom than to attain the requisite size before flowering commences; consequently, they should now be examined, and, if necessary, at once moved into larger pots, using good loam made tolerably rich and not too much sand in it, potting them so as to make the whole mass pretty firm, which will have the effect of producing shorter-jointed wood than that which results from the soil being left comparatively loose and open in the pots. Keep them close to the glass where they will be fully exposed to all available light, in a temperature of from 45° to 50° in the night and proportionately higher by day, according to the state of the weather, stopping the shoots as occasion requires. One stroke to the leading growth will be sufficient, as a well-managed Fuchsia, grown in the usual pyramidal style, does not need more than this.

Berry-bearing Solanums.—Where the pseudo-capsicum variety of these plants is grown from seed of even a good strain, a few will be found very much superior in their general habit and the freedom with which they produce their fruit, and if these are selected alone to propagate from, the stock will be more satisfactory. If plants have not already been struck, no time should now be lost in

getting them in, otherwise they have not time to attain a useful size so as to enable their carrying a full crop of berries; they will root in a few weeks in a moderate heat. Where they are to be grown from seeds this should now be sown and every means taken to get them on without delay. Plants of last year, or older, that ripened their berries earliest in autumn and have now got shabby, should at once be cut in freely and placed where they will receive the temperature of an ordinary greenhouse, as they are no better for being stimulated by heat. If they are well managed through the summer, either by shaking them out, repotting, and growing on in the pots plunged, out-of-doors, or, still better, planted out, provided this is done early enough to get them on into bloom, they will set a crop of fruit that will get fully ripe and coloured soon in the autumn. Standard examples grown on stems from 1 ft. to 2 ft. in height are very effective amongst other things. The favour which this Solanum has found has, with many growers, thrown the old *S. capsicastrum* into the shade, yet the latter is a more elegant plant and quite as deserving of cultivation as the erect-habited kind. It will succeed treated similarly in every way.

Callas.—Plants of these that were forced into flower to come in at Christmas, should, where so large as to require it, now be divided, placing the crowns one in a pot, as in no way do they look so well, or are so useful as grown singly. By dividing them thus early, and putting them where they can at once commence growth, the strongest ought to be in a condition to bloom correspondingly soon next autumn.—T. BAINES.

Flower Garden.

Auriculas.—The frost has not yet given way sufficiently to allow of any development on the part of the plants. If a good rest be beneficial to them it has certainly been obtained this year. The outer leaves continue to decay, and it has not been easy to get at the plants to remove. As soon, however, as the frost gives way, the whole should be overhauled, and the surface soil removed, to be replaced with the rich compost previously recommended. A Lancashire grower, writing a week or two ago, is puzzled to know why I recommend protecting the plants from frost so early in the year. The only reason I can give is the exceptionally severe winter. Until this year ours have never been covered until after they were top-dressed in February, when I found the leaves thickly crusted with frosty particles, and ascertained that this could be prevented by placing mats over the glass it was done. The grower in question found that the leaves of his plants were dry when the ventilators were open night and day, but he does not approve of allowing the keen, frosty wind to blow upon the plants. Still watch for insect pests, as they do more mischief this and next month than at any other season.

Carnations and Picotees.—Read up what was stated last week concerning these, and see that aphides are destroyed by fumigating. Admit plenty of air whenever the weather is favourable, sometimes even removing the lights entirely. Perpetual-flowering Carnations and yellow ground Picotees, such as Prince of Orange, Oscar, and Ascot Yellow, should now be propagated by slipping off the small side growths, and inserting them in 5-in. pots in light sandy soil. The pots should be placed in a propagating house or hot-bed.

Dahlias.—Refer to last week's remarks concerning preparations for propagating. If there be no other convenience for this than the ordinary garden frames, some fermenting material must be prepared for that purpose without delay. Many have no choice, and can only obtain stable manure. This is certain to heat, and that violently, but it does not last long. I have obtained a steadier heat from worthless Tussock Grass cut from a wet meadow and mixing it with the manure. The best material is leaves and manure in equal proportions; the whole ought to be thrown into a heap and turned over twice, viz., six days after the heap was formed, and six days after it was turned. In a few days more the bed may be made between 3 ft. and 4 ft. high. Put in about 6 in. of leaf-mould or Cocoa-nut fibre refuse, and the frame will be ready to receive all sorts of cuttings.

Hollyhocks.—Cuttings or root-grafts may also be propagated on a hotbed such as that described; they must be taken from the plants as soon as they are ready for removal. Exhibitors need not be told to get beds or borders prepared for their reception by trenching, for this has no doubt been done long ago, and the soil will have been tempered by exposure to the winter's frost. If such work has not been done see to it as soon as the frost breaks up.

Pansies.—Those in pots in well sheltered positions and in frames protected by mats are beginning to make some progress, and they would make good progress if we could get a glimpse of sunshine for an hour or two each day, but near London this has not been the case.

If the plants be not yet in their flowering pots see that that is so at once. Those that have been potted must be kept fairly moist at the roots.

Primula cortusoides amena.—The sight of the tender young leaves of this beautiful Primrose, with their accompanying flower trusses in course of development, is most satisfactory to the cultivator. If the plants are in frames see that they do not suffer from want of water, and it is desirable not to allow frost to reach them. If the plants be in the greenhouse see that red spider does not attack the leaves.

Tulips.—When the frost breaks up these will most likely develop rapidly. At present most of them have their heads hid underground. Our rainfall last year was but 29 in.; during some seasons it is not over 21 in. In districts where this amount is doubled, or nearly so, some sort of covering is necessary to throw off such an excess of wet. If this has not been done many bulbs will suffer owing to their not starting rapidly enough. Under such circumstances the value of beds raised 9 in. or so above the surface, also deeply trenched and well drained, will be apparent. Those who have old frame lights to spare will find that they answer better than anything else for throwing off wet.—J. DOUGLAS.

Public Parks and Open Spaces.

Borders which contain herbaceous plants must at this season be carefully looked over, otherwise many which are making underground growth, being tender, are liable to attacks from slugs and other insects. A light dressing of salt, soot, gas ashes, or even common furnace ashes, will be found very beneficial in preventing injury. As a rule herbaceous borders are out of place round shrubberies and plantations, the shrubs in which, if judiciously planted, should be allowed to form the outline. Nothing can be more in conformity with a natural landscape than the easy sweep of many of our evergreen shrubs when allowed to form themselves to the turf, resting upon it, as it were. A herbaceous border may with propriety be placed by the side of roadways where a belt of trees and shrubs has been planted to shut out buildings or other objectionable features; the border should be ample, not less than 10 ft. to 15 ft. in width, and composed of rich materials, as, where trees and shrubs are growing near, the soil is rapidly impoverished. The frost and outting winds will have injured many shrubs more or less; it will, however, be better to wait until the end of the month before any attempt is made to prune away injured portions. Those who contemplate planting trees on street margins should do so before the end of this month. Lawns will require special attention during this month; they should be well rolled on every favourable opportunity, in order that the soil may be kept tightly to the roots, every frost having a tendency to raise the surface. Should Moss exist in the Grass, which as a rule denotes bad drainage, it is well to thoroughly rake over the surface, uprooting the Moss, and then sweeping it off with brooms nearly worn out. A mixture of fine lawn Grass seeds should then be sown, and a fair sprinkling of rich soil, sifted fine, thrown over the surface. Seed should be sown at the rate of one to three bushels per acre, according to the state of the plot treated; it must then be brush-harrowed, and firmly rolled down. Much benefit will be the result if this work be well done. In all populous towns this is an annual operation, inasmuch as the state of the atmosphere is very destructive to Grass. As soon as the Grass shows signs of growth, the mowing machine or scythe should be brought into use; this if done as early as possible and at least once a week, will improve the Grass. A mixture of soot, salt, and lime spread over the surface at this season, will do much to deepen the colour of the Grass and destroy many injurious insects. In towns where it is desired to have an early display of certain varieties of annuals, it is necessary to sow some seeds in pots, and place them in cold frames plunged in coal ashes or similar material; in this way the smoky, damp atmosphere and also the ravages of birds may be successfully combated, as when the seedlings are strong enough to withstand these baneful influences, they are transplanted into the open ground; seeds of the more hardy varieties may also be sown out-of-doors towards the end of the month. Should any plants of perennials remain in the nursery beds, they should be planted out on the first favourable opportunity; thus Acanthus, Fennels, Geums, Sweetwilliams, &c., may be transplanted very successfully. Walks and roads upon which weeds have been troublesome during the preceding summer, should be lightly broken up with a pick, and the surface which will be found to consist principally of soil and decayed weeds, should be raked off. A thin coat of fine gravel spread over the surface will, when rolled, give them a clean and fresh appearance; if, before the gravel is put on, a sprinkling of salt, or a good watering with carbolic acid and water, one of the former to ten of the latter be given, it will very much assist in pre-

venting the growth of weeds during the year. Care must be taken, however, that neither salt nor solution is applied near Box, turf, or other growing edgings. Tar-paved walks are free from these objections, and are well worth a trial. The month of February will afford an excellent opportunity for clearing out any accumulations which exist in lakes. If the water can be easily run off, the mud will soon be in a condition fit to be wheeled out in barrows. A little lime thrown over the surface will prevent any disagreeable exhalations; should there be any signs of leakage in banks or bottom, clay puddle, concrete, or other suitable material, should be used as a preventive.—CHARLES DENNIS, *Southwark Park.*

TREES, SHRUBS, & WOODLANDS.

PINUS LARICIO.

I AM not sure that Mr. Baines (p. 106) is right in concluding that prejudice is the only reason why *Pinus Laricio* (the Corsican Pine) has not been planted more extensively in this island. I have had a short experience of the tree, having commenced planting in 1868, when I set to work to learn the history of all the trees enumerated in nursery gardeners' catalogues. The splendid specimen of *Pinus Laricio* at Kew had attracted my notice, and as I read that the tree produces valuable timber, that it is proof against the attacks of rabbits, that it is quite hardy in all situations, of very rapid growth, and handsome robust habit, I determined to include it in my planting. I have planted several hundreds in various situations in the last ten years, and am glad for the benefit of others to give my experience. The statements about hardness and rapidity of growth are quite correct. *P. Laricio* grows faster than any other Conifer I have tried, including *Abies Douglasii*, and *Wellingtonia gigantea*; its average annual increase in height has been more than 2½ ft. The statement about its being proof against the attacks of rabbits must be received with some limitation; rabbits do not like its bark or leaves so well as those of most other Conifers, and will only attack it when hard pressed. It is curious to see how much they prefer the closely allied species *P. austriaca*. In my experience I have found only three plants quite proof against rabbits; viz., the *Rhododendron*, the Yew, and the Box. But there are objections to *P. Laricio* which I must now mention. First, it is difficult to establish. Those bought from nursery gardens, if of a sufficient size for planting out, generally die after transplanting. I bought several lots from different nurseries, of which hardly one survives. I then bought a two-year-old lot in a seed-bed containing several thousand, moved them to my own nursery, and though a large proportion died I saved enough for a good stock. By transplanting them every year I found I could do well with them, but not otherwise. If left unmoved for two years, they make a large top-bearing shoot, and will not move well. Their root is small, weak, and shallow in proportion to their upward growth, and this is the cause of another, the most serious objection of all. Of those I have planted in various spots, half have been blown down when they reached a height of from 15 ft. to 20 ft.; it is a tree, therefore, which will not do in any place exposed to high winds. If planted in a mixed plantation it outgrows its neighbours, and, having half smothered them, completes their destruction by falling upon them. I am told, however, that this rapidity of growth ceases after a few years, and that at the age of twenty or thirty *P. Laricio* is often passed by Scotch Fir of the same age. I have also heard that it was planted to some extent when first introduced, about the middle of last century, and found to be a failure. I should like to obtain more information on these points. Have any of your readers seen a plantation of *P. Laricio* thirty or forty years old? and, if they have, how does it compare with Scotch Pine in the same neighbourhood.

Edge Hall, Malpas.

C. W. Dob.

—In many situations *Pinus Laricio* beats the Scotch Fir. The latter is also one of the most useful of trees, far preferable to Larch, which is now so subject to disease as hardly to be worth planting. The *Pinus Laricio*, as a rule, also escapes the ravages of rabbits; this renders it still more valuable in exposed localities. I have recently seen some beautiful plantations of this *Pinus* planted from seven to ten years ago. It grows very fast, and is one of the hardiest, as well as one of the most useful of all the Firs.—D. T. Fish.

Facts about the Japanese Persimmon.—The Japanese Persimmon is a dark-stemmed tree with large glossy leaves. It seems to somewhat resemble, in its method of growth, an Angiers Quince tree, but the leaves are larger, and the tree is handsomer. It buds and grafts readily. The fruit is produced on the new wood of spring growth, blossoms appearing in April, the fruit not being fit to

gather until after the leaves fall. The fruit is not usually good until it has lain in the dark for some months, and has become soft. The trees are hard to transplant, unless great care is taken. It appears probable that the Persimmon prefers a rather moist location. It promises to be an immense bearer. One orchard of 1,200 trees, planted for market, lies near San Jose.—C. H. SHINN in "Country Gentleman."

WINTER-BLOOMING HARDY SHRUBS.

Chimonanthus grandiflorus.—This most fragrant and free blooming of all winter-flowering hardy shrubs is now about at its best in a rather sheltered corner of my walled-in kitchen garden, and is most useful for cutting from now that there is such a scarcity of any kind of flowers, and its blooms last many days in perfection in water after they have been taken from the tree. This large-flowered variety of the better known and much more generally grown ordinary *Chimonanthus* (or, as some still call it, *Calycanthus præcox*) is in every respect superior to it, and much to be preferred to it, as, in addition to the individual blooms being very much larger in size, they are also much brighter, being deep straw coloured, whereas those of the ordinary variety are only dull white, of a somewhat dingy hue. It is also a very much more abundant bloomer, an almost equally large bush at the opposite corner of my garden of the common variety having only an odd bloom here and there scattered over it, whereas the large-flowered kind is literally covered with bloom from top to bottom. The perfume much resembles that of a Jonquil.

Hamamelis Zuccariniana.—In addition to the curious and pretty *Hamamelis arborea* mentioned (p. 101) by Mr. Ewbank (and which is also now in bloom with me) there is another variety of this curious family, *H. Zuccariniana*, which is, I think, even more profuse-blooming than the first-named variety, though somewhat later in opening its blossoms, which are also slightly smaller in size and of only one colour, pure golden yellow, being without the internal claret-coloured cup possessed by the flowers of *H. arborea*. In about a week's time from this my plant of *H. Zuccariniana* will be covered with its tiny, golden, starry blossoms. I may add that it is to be obtained from the same prolific source from which Mr. Ewbank obtained his plant.

W. E. GUMBLETON.

RATE OF GROWTH AND QUALITY OF TIMBER.

This question is now getting, as discussions of a similar nature often do, obscured through importation into it of a good deal of irrelevant matter. "C." says "I surely do not mean to assert that the trees, whether exotic or otherwise, which are grown for timber in this country, are governed by different laws from those to which they are subject elsewhere." If in this "C." means to say, and his words admit of no other interpretation, that the nature of the wood of a tree, in other words, its quality, is not influenced by the soil and climate—country if you will—in which it is grown, he makes an assertion that will surprise most people practically conversant with timber. Most emphatically do I say that the quality of wood, and to a very great extent, is influenced by soil and climate. Further, in mentioning the constituent parts of which timber, like other vegetable matter, is composed, "C." falls into another error which points to his deductions being drawn from theory alone. He speaks of the fibro-vascular tissues as being strong and enduring, of which any one acquainted with the subject, even remotely, is aware. But does "C." mean to make out that the strength and endurance of all vegetable substances are alike in proportion to the quantity of this fibre present? It is just such mistaken conclusions as this upon which nine-tenths of the fallacious theories rest that are thrust upon the world, and which are expected to be taken unchallenged. I have, through a tolerably lengthened acquaintance with the growth and uses of a considerable number of plants from timber trees down to things of much smaller growth, been pleased to find the hypothesis of the physiologist, in accordance with the results of actual experience, but I have very often found them far from being so, and in nothing so much as in the assumed and real qualities of many kinds of timber. The extreme cases mentioned by "C." of the difference existing in the strength of the wood of different trees of the same species—produced on the one hand under free, healthy conditions of growth, and on the other resulting from a stunted, unhealthy state—have, as any impartial observer can see, nothing to do with the question.

T. BAINES.

Pernettya mucronata in Devonshire.—When I took charge of the gardens here, twenty-one years ago, we had only one plant of this beautiful shrub, which has annually had its branches heavily laden with berries. It is now 6 ft. high, and occupies a terminal

position in front of a large group of shrubs. From a small branch, thickly set with berries, I saved the seed, and raised in pans in a garden frame a large number of seedlings, many of which are now good-sized plants. These, even when small plants in nursery beds, fruited freely. We use them for foreground plants in clumps or groups of shrubs, and with good effect. These *Pernettyas* have a tendency to make shoots yearly upwards of 2 ft. long; these should be shortened back so as to induce a thick, dwarf growth, on which the berries are most freely produced. The plants require protection from hares and rabbits, which are very fond of them. Galvanised wire netting placed round them answers that purpose until the plants are sufficiently large to stand uninjured. They grow very freely here in light loam, and throw up quantities of suckers from which plants may be reared. These *Pernettyas* are very useful for furnishing cut flowers in spring and in winter; the berries are suitable for ornamenting vases, that is, if protected from birds with a piece of netting. Varieties which grow very freely and strongly have never produced a berry here, although in the same ground and under exactly the same treatment; much, therefore, depends upon having the true variety of *P. mucronata*. It is perfectly hardy, having withstood the winters of 1860 and 1866, and the late hard weather quite uninjured.—J. GARLAND, *Killerton, Exeter*.

HARDINESS OF THE HYDRANGEA.

I WAS just going to criticise "a Retired Gardener's" remarks under this title (p. 42), but on reading them through I find they come to the same conclusion which I have long reached; viz., that the *Hydrangea* is not hardy except in the southern counties. It will certainly live out-of-doors, but it will neither thrive nor flower to any useful purpose. Such at least is my experience with it in East Anglia; I have even tried protecting it, but to no good purpose. Your correspondent is quite right about Devonshire being the place for *Hydrangeas*, huge bushes of it rising to the size and importance of shrubs, some flowering blue, others pink, have a magnificent effect in beds, borders, or in front of shrubberies. But the place for *Hydrangeas* in most other parts of the kingdom, is the cool conservatory or window garden. Plants in 8 in. pots with half-a-dozen large blooms, are highly ornamental; but, perhaps, small single-stemmed plants are even more beautiful. A good way of preparing these, is to insert cuttings of the strongest roots either in the autumn or early spring. They root very soon in a gentle heat, when they should be shifted into a 6 in. pot, using equal parts of loam and well rotted manure. Place them close to the light so as to keep strong and sturdy, as well as dwarf. Plants so treated and never allowed to flag, will throw enormous trusses of bloom almost covering the leaves, and look remarkably well. To insure blue flowers, obtain soil, either peat or loam, from a district which changes the flower to that colour. The use of steel filings or the iron sparks from a blacksmith's anvil mixed freely in the soil, will sometimes change the flower to a blue colour and sometimes not.

D. T. FISH.

The Gladwyn v. Holly Berries.—The *Holly* being rather an uncertain fruiting plant, I would recommend all those who require berries for purposes of decoration at certain times of the year to plant the *Gladwyn* (*Iris fætidissima*). This, once established, will take care of itself, and never fail to produce beautiful pods filled with coral-like berries that are always acceptable. Although, like many other plants, it does best in a good situation, yet it will make itself at home anywhere in shrubberies where it can get light and air. The seeds do not vegetate the first season; therefore it is best to sow them where they will not be disturbed and the plants will come up in abundance the next spring. In some localities it grows wild, and both plants and seeds are plentiful. When past its best for decorating purposes, I scatter the seeds in the shrubberies, where we get plants by the hundred. Rabbits will eat them in their young state, but not after they have become well established.—W. DIVERS, *Wierton*.

Nursery and Seed Association.—We have received from Mr. Charles Lee, the Treasurer, the second annual report of the Committee of Management of this Association, the objects of which are to protect and promote the business of nurserymen, florists, and seedmen in the United Kingdom and abroad; to collect and disseminate information calculated to protect the members of the Association from fraud; to arrange for the speedy and economical collection of debts due to members; the establishment of unity amongst those interested in the welfare of the nursery and seed trade; the encouragement of the interchange of opinions on questions of importance relating to such trade; the doing of all such things as may be incidental or conducive to the attainment of the above objects, and all such objects as may from time to time be determined by the Association.

THE INDOOR GARDEN.

TOBIN'S SYSTEM OF VENTILATION.

FROM what I have seen of this system as applied to dwelling-houses, I do not see the least difficulty in applying it to hot-houses for winter ventilation; I am afraid it would not be sufficient in summer. The plan surpasses any other yet tried of admitting air without injury to the inmates of the structure, and has proved a complete success in houses and public buildings where it has been adopted. The idea, I am informed, was suggested to the discoverer in the following way, which will give one as good a notion of the principle of the system, as any description that could be furnished. Mr. Tobin was watching a strong stream of water, from a pipe, running straight into a tank at one end, and observed that the current from the pipe did not mix with the water of the tank on entering, but rushed direct towards the other end, against which it struck and then spread out right and left, with decreased force, and gradually flowed back along the sides of the tank to the end where it had entered, but with scarcely any perceptible disturbance of the water; many a one must have noticed the same thing. The tank represents the room to be ventilated; the end where the water enters the floor, and the opposite end the ceiling. If we suppose that the pipe carried half or two-thirds of the way up the tank, instead of terminating at the end where it enters, we have the Tobin system complete. In a hot-house the usual top ventilators would remain closed, and the fresh air would be delivered above the tops of the plants or a little below the roof, and would gradually descend to the floor among the plants. Exactly the same thing takes place when a smoking-pipe is set down on the floor of a hot-house, and the top shutters are closed. The smoke ascends in a straight column to the roof, and then rolls down the side of the house till the latter is filled to the floor. The Tobin system might be applied to hot-houses—particularly span roofed structures—with the greatest ease, and the expense of adopting it would hardly be worth mentioning: simple methods of applying it will suggest themselves to any one.

Speaking of ventilation generally I am of opinion that the evils attributed to our present methods of ventilating are greatly exaggerated. In plant houses where the plants stand close to the side ventilators, it is necessary to exercise care in opening them in cold weather, but that is seldom or never necessary, as a little air at the apex of the roof will generally be found sufficient, and ventilation can be given there during the coldest weather without injury to the inmates, as is demonstrated by every-day experience. As to the evils that are said to have been wrought in fruit houses by the present system of giving air at the lowest and highest points of the houses, particularly front air, I must say I never had any experience of them, and I doubt if any other system will be devised that will meet the end in view so well, all things considered. As to front air it may appear heterodoxical to assert that admitting air at the front of the house is safer, even in cold weather, than admitting it at the top; but I believe that is so myself, and I have acted on that belief for many years, and found it to be the best plan. Muscat Vines, when in flower and just at the setting period, are considered about as sensitive subjects as any that one has to deal with, but I should be perfectly willing to let any one regulate the ventilation by the front shutters during the whole of the season without fear of rusty berries, bad setting, or any other mishap. One practice in all our fruit houses is to open the top ventilators an inch or so, and afterwards regulate the temperature by the front shutters; that is when ventilation becomes necessary, for I do not believe in creating the necessity by giving too much fire-heat. Still, in such cold, dull weather as we are experiencing just now we fire up sufficiently to enable us to admit a little air.

J. S. W.

Hardy Primroses under Glass.—For several winters I have had coloured varieties of garden Primroses in bloom more or less the whole winter through. Fearing a sharp winter, I lifted a number of plants and replanted them under glass in a temperature of from 40° to 45° and they have well repaid the trouble by a fine display of bloom, while those that are out-of-doors still look as if spring was yet in the remote future.—J. G., *Linton*.

BOTTOM HEAT.

MR. SIMPSON does not take the usual course of directing his objections to what I have written on this subject to the paper in which the article appeared, where, in its entirety, it could speak for itself. If Mr. Simpson had a single practical proof to advance in support of his views, he would not be put to the straits of quoting the Chiswick records, which, as he knows well, relate to our own country, where the conditions of earth and air temperature are so different from those of the countries from which come the plants which we grow under glass in heat. When I first began plant growing I read everything I could lay my hands on bearing upon the subject of temperature in the countries from which the various plants that I cultivated came, but after shaping my practice in conformity with the theoretical conclusions held by those who wrote on these matters, I found that I could grow them very much better by treating them in accordance with what I had proved to be better suited to their requirements, the details of which I gave fully in the communication from which Mr. Simpson quotes, and, moreover, the plants, not few in number, nor confined to a few families grown under the exact conditions which I there described, were, for a considerable number of years, seen by the majority of people connected with gardening pursuits. There they were to give evidence far more unmistakable than Mr. Simpson's borrowed theories, to which, during the two years this discussion, in one shape or other, has extended, he has persistently clung, without an atom of proof to sustain them more substantial than the untenable doctrine that because there are some plants from warm latitudes that succeed better with bottom heat than without it, all, or even the majority, do so, totally oblivious of the fact that the habits and requirements of the plants from any given country are as different often as their external appearances. I may remind Mr. Simpson that reiterated assertion, however long persisted in, will never upset an accomplished fact. When I was Mr. Simpson's age I suppose I had had about as much experience in plant growing as he has had, and I was as staunch a believer in the use of bottom heat as he is, but I did not shut my eyes to facts that came before me, some resulting from accident others from experiments attentively observed. All I have said on this, as on any other subject upon which I ever write, I have previously proved in a way that does not admit of mistake, and in the case of bottom heat not once, twice, or thrice, but over a series of years, with a large number of species of plants. A considerable number of the best plant growers in the kingdom know, from what they saw when they used to call upon me, that for many years during the latter portion of the time I was engaged in plant growing none were ever subjected to bottom heat in any way whatever. Can Mr. Simpson controvert this? If he can, he will do more to make out his case than all the theories he can rake up from the writings, or conjectures, of other people. In what I have written on the subject, I have done nothing more than simply state the results of my own practice, which was already as well known in all its details to many as it was to myself. There were the facts of the case, and whoever felt disposed to test them might do so. Had Mr. Simpson done this, and failed after a fair and impartial trial, the objections which he has raised would have some show of reason attached to them. Whatever objection Mr. Simpson might raise against the theory connected with the subject I have advanced, he cannot ignore the indisputable facts afforded by the plants I so long cultivated, under conditions exactly in accordance with what I have written.

T. BAINES.

PLANT AND FRUIT CULTURE COMBINED.

It is an old saying that plants and fruit cannot be grown well together, but no assertion could be more incorrect, and the wider it is made known that the very opposite is the case the better. In support of this, perhaps I had better state my own experience in the matter first. Our Vineries, Pineries, and Peach houses here are continually full of plants of some kind or other; nevertheless, they all succeed admirably, and the fruit crops are all that need be desired. A succession of plants and flowers for a very large conservatory is constantly being obtained from the fruit houses all the year round, and not only are flowers grown in them, but French Beans in pots, Strawberries, &c., and altogether we consider this mode of utilising houses by far the most profitable. The very last thing we would think of doing would be keeping our fruit houses free from plants. Ferns do better under the shade of Vines than elsewhere, and so do all kinds of plants that are newly-potted, especially in early summer. When shelves are fixed at the back of lean-to houses, about 2 ft. from the glass, they are extremely useful for putting all kinds of flowering plants on after they are lifted from the body of the house. In span-roofed houses a shelf under the central ridge just over the pathway

serves the same purpose. Then there is an angle along the front where the sides join the roof that forms a capital place for a shelf; in fact, all who are inclined to grow plants in fruit houses will soon find out plenty of convenient places in which to put them, and where this is done there is not the slightest danger of their health being injured or anything at all befalling either plants, flowers, or fruits. Allow me to ask those who think this wrong why plants and fruit should not succeed together? and if instances can be pointed out in which either the one or the other failed when grown under skilful management? In this way, judging from what I have seen and from what I have read in *THE GARDEN*, I should say that most of the market gardeners about London and elsewhere make a regular practice of growing fruit and flowers in the same houses, and it is well known that these cultivators grow their productions to a state of as great perfection as need be desired.

CAMBRIAN.

CYPRIPEDIUM INSIGNE MAULEI.

This is not one of the newest, but it is still one of the best of the *Cypripediums*, as well as one of the dearest priced. I have reasons for thinking that *C. insigne* is sometimes grown for it, but the one cannot be mistaken for the other by any one acquainted with both; *Maulei* has much the prettier flower; it is better marked; but its distinguishing characteristic is the much larger patch of pure white on the upper petal. It is a very effective plant when well flowered, and the flowers are also good for cutting for bouquets, or at least vases of flowers. Either on the plant or in a state they last a very long time, about three months on the plant. Those who do not grow Orchids as a speciality, but only such as can be grown well and easily amongst an ordinary collection of stove or intermediate house plants, should find a place for this *Cypripedium*. Like most of the species, it does not fail to grow vigorously and flower freely, unless absolutely ill-used. Old plants of it divided into pieces with roots to each will soon furnish a good stock of plants. Some growers recommend pure fibry peat as a compost for *Cypripediums*, others Spaghnum chiefly, but I remember Mr. Parker, of Tooting, telling me that they liked a more substantial diet if they were to flower well, and since then I have potted our plants, different strong-growing kinds, in good fibry loam, peat, sand, and obarcoal, and in this compost they root and grow with great vigour, and flourish much better than they did in peat alone. They must, however, have plenty of drainage, and not be placed in a deep potful of soil which becomes inert beneath the plants, as the roots do not enter it but keep rooting near the surface.

J. S. W.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Plants for a Small Greenhouse.—There is a wonderful variety of plants that do well in a cold greenhouse. A temperature of from 35° to 40° is excellent for winter purposes, except that in such a temperature it is not possible to have in midwinter other than the hardiest and earliest plants in bloom. Roman Hyacinths, Christmas Roses, Primroses, Camellias, *Primula denticulata*, &c., will yield the very earliest bloom in such a temperature, and to these will follow Chinese Primulas, *Cyclamens*, *Cinerarias*, and herbaceous Calceolarias, all of which will live well in a cool house through the winter, provided frost be excluded. Genistas, Coronillas, *Deutzias*, *Dielytras*, and Early Azaleas follow in succession, and furnish an abundance of bloom. For the summer season the best plants are show and zonal Pelargoniums, *Fuchsias*, Balsams, *Begonias*, and similar plants, all very gay and decorative and easily managed. These will keep the house gay until autumn, when *Chrysanthemums*, *Solanums*, &c., might terminate the year. To these an abundance of plants can be added, but the dimensions of a small house are so limited that it would be useless to suggest, more especially for summer decoration, where a Vine in foliage will exclude light and render the cultivation of plants difficult. A quantity of hardy early spring flowers, such as bloom naturally in the open ground in March and April if lifted into pots and placed in such a house early in winter, will commence to produce bloom much earlier, and prove most valuable for decoration before other and tenderer plants have commenced to flower. A few Roses in pots brought into the house early will bloom a month before those out-of-doors. These can be returned to the open air as soon as the bloom is over. A few tree Carnations in pots will yield winter bloom, and furnish some fine "button-holes." Common Auriculas in pots are pretty on a front stage, and do admirably with Chinese Primulas and *Cyclamens*. The obtaining of flower all the year round is difficult to accomplish without strong artificial heat, but the plants named above, if properly treated—a

matter, be it understood, of the first moment for their welfare—will give a very long season, although the artificial heat be wanting.—A. D.

—Among Mr. Groom's useful list of conservatory plants (p. 96), I am rather surprised to find the two *Hedychiums*, coronarium and *Gardnerianum*, and *Monstera deliciosa*. Had not *Camellias*, *Azaleas*, &c., been named in the same connection, one would have thought these were meant for the summer furnishing of the conservatory. Of course a good deal depends on the temperature. But as not a few this winter could not keep their conservatories above 40°, such plants, and even the hardier *Ficus elastica*, would have looked very seedy, had they been subjected to such a low temperature; few plants pay better for a genial warm temperature than the two *Hedychiums* here named and the *Monstera deliciosa*, which deserves a warm house and a tank to itself, alike for the unique character and beauty of its leaves, and the high quality of its luscious fruit. D. T. FISH.

THE KITCHEN GARDEN.

CROPPING KITCHEN GARDENS.

THE commencement of a new year is a good time to begin noting down anything that is worth remembering in the daily events that are constantly occurring in all gardens. Habits of order and method are fostered by it, and much useful information is gathered together that will have an influence for good in after life. The natural conditions of no two gardens are exactly alike; hence the necessity for constant thought being brought to bear, especially upon the cropping of the kitchen garden. A well-supplied kitchen will often cover mistakes in other directions, but, as a rule, the man who can supply the kitchen well at all seasons possesses the qualities that will insure success in other departments, if he only gives due play to his energies. The great aim of the kitchen gardener should be not only to have everything of the best, as regards quality, but to have all the successional crops meet each other. A superabundance of the most superior produce at one time will not compensate for a scarcity at another. In keeping up a regular supply of vegetables there are two matters especially important; the first is to sow or plant the right kinds at the proper seasons for succession, and the second is to sow or plant just the right quantities. For instance, in the case of Cauliflowers, Lettuce, or any other crop that is apt to bolt prematurely, or, at any rate, is much influenced by the seasons, sowing little and often should be the rule, at the same time taking advantage of the various aspects of the garden to suit the different crops to the varying seasons. There is no doubt that the majority of kitchen gardens are too much shaded and sheltered by fruit trees. The best vegetables are invariably produced in the large open spaces where the air can freely circulate amongst them. A warm sunny spot under a south wall is a very desirable place for early crops, but the wants in this way are small in comparison with the requirements of the whole year. In a maggot-infested garden there should be no main crop of Carrots, but, instead, a regular succession of sowing monthly from the forced crops under glass in January till the last sowing of Early Nantes to stand the winter in the border in the first week in August, and which can be sheltered in very severe weather with a sprinkling of dry, loose litter. Good sweet young Carrots can be had all the year round in this way, without taking up more land or costing more than if the main-crop sowing had been relied on for a good part of the year's supply; and even where a clean crop free from maggots can be grown, the old roots lose flavour before the young forced crop comes in, and the plan of sowing small successional crops will be found more satisfactory. In a less degree the same remarks apply to Onions. Where the maggots are troublesome the autumn-sown crops generally escape their attacks, and this fact should lead us, if we have any doubt of our soil, to sow at least a good half of the year's supply at that season. A rough plan of the kitchen garden is a great advantage in working out the season's work; it should be drawn to scale, and the crops now occupying the ground marked on it. The more a subject is thought over the easier and simpler it becomes; and if a thing is often present in the mind fresh lights are constantly breaking in upon us, and I suppose no one is so perfect in anything as to escape the necessity for wishing or trying to improve.

E. H.

Early Peas.—In most places Peas sown in autumn, unless covered with glass, will this season be a failure, but he who takes time by the forelock will be prepared for this, and there is more than one way of filling up such a vacancy. The simplest and, perhaps, on the whole, the best, is to sow again about the middle of February as many Peas in 5-in. pots as will make good the loss. The pots may

at first stand under a stage, or in any position where a little warmth can be afforded them; but, as soon as the green tops push through the soil, they should be taken to a cold pit or frame, and have plenty of ventilation till the weather is suitable for planting them out, which will generally be about the middle of March. There are warm south borders in every garden available for the earliest crops, and if they can be planted near the foot of a south wall they will sustain no check. The planting should be done when the soil is in a good mellow condition. The sticks should be placed to the rows at the same time, and a few Yew or evergreen branches of some kind should be placed on the windward side to afford shelter. There are other ways of forwarding early Peas under cover all more or less useful, such as cutting pieces of sod about 1 ft. long and 6 in. wide, scooping out the soil along the centre, sowing the Peas, and covering with light, rich soil; then they should be placed in a frame where there is a little warmth, and, after undergoing the hardening process, planted out turf and all, without disturbing the Peas in the drills in the border; a ridge of warm, mellow soil should be drawn to each side of the rows. Early Peas should be planted rather thick, as it is not often they yield more than one or two good gatherings, and the second crop comes in so quickly after them, that they are not required for continuous bearing, even if they were adapted for it, which they are not. If the roots are broken or disturbed the crop will not be so good, as Peas do not transplant well if the roots are broken. I have sometimes transplanted them, when quite small, from boxes where they had been sown thickly, taking them up in little patches, and transferring them at once to the drills, but I have always found the less the roots were disturbed the better the crop turned out. For the earliest crop there is nothing much better among white Peas than Ring-leader. William the First is a most desirable kind to sow early in the open ground.—E. H.

GARDEN DESTROYERS.

THE LACKEY MOTH.

(*CLISIOCAMPA NEUSTRIA*).

This well-known and common moth, though very similar in its destructive habits to the small ermine moth described in a recent number of *THE GARDEN*, belongs to a very different family (*Bombycida*, the family of which the silkworm moth is

Clisiocampa (Bombyx) neustria.

to lay their eggs on a small bough or twig of a tree. This they do in a very curious and beautiful manner, placing them one after another close together in a spiral line round the twig. The spirals are formed close together, so that the eggs in the second turn touch those in the first; in this way some 200 or 300 eggs are laid, forming a band round the shoot, composed of from fifteen to twenty turns of the spiral row of eggs. The interstices are filled up and the band covered with a kind of dark brown varnish, which becomes so hard when dry, that it is almost impossible to remove the eggs without the assistance of a knife or other instrument. The eggs are thus entirely protected from the attacks of birds and other natural enemies, and from the effects of bad weather. The caterpillars are not hatched until the following spring, in April or May, when the leaves are beginning to appear on the trees; they at once begin to form a nest or web of silken threads generally in some fork among the smaller branches. In this nest they live during the day, and in bad weather, and from which if disturbed they immediately let themselves fall by a thread to the ground. At night they leave the nest, and feed upon the neighbouring leaves, spinning a thread as they go, by which they return to their shelter at daybreak. As there are often 150 to 200 caterpillars thus congregated together, it can easily be imagined what an amount of mischief they commit. As they increase

Caterpillar of *Clisiocampa (Bombyx) neustria*, cocoon, and commencement of a band of eggs.

a member). The males of most of the species of this family are endowed with a peculiar faculty of discovering the females, even though they may be entirely hidden from their sight. This fact is often taken advantage of by collectors of moths, who, having obtained a female, carry it in a box covered with gauze to any place where the males are likely to be found, and if there are any about they are sure to congregate round the box. It is not known by what sense the males are thus directed to the females, but probably it is by sound or smell, as is the case with all insects of this order. The Lackey is only injurious to vegetation when in the caterpillar state, but in this state it at times does an immense amount of mischief. It is a very promiscuous feeder, the leaves of few trees coming amiss to them; they will even eat the leaves of Fir trees, Oaks, Elms, Beeches, Poplars, and fruit trees, are, perhaps, their favourite food, as the caterpillars form a kind of net or web in which they may be found during the day. The easiest way of destroying them is by crushing the nests against the boughs with a stick or pulling them out of the trees and destroying them. The rings of the eggs may easily be found if carefully searched for, and should not be merely detached from the trees and thrown away, but should be destroyed by crushing them against some hard substance. The cocoons should always be destroyed when met with. Several kinds of ichneumonids are parasitic on the caterpillars, and are a great assistance in keeping this insect in check. The moths make their appearance early in July, and, after pairing, the females at once commence

in size they change their skins several times; when they have attained their full size, which they generally have by the middle of June, they no longer continue to live together, but disperse, and each searches for a suitable position in which to undergo the change to the chrysalis state. They generally select two leaves which happen to be close together, or some sheltered spot on a wall, paling, or tree-stem, and there spin their cocoons, within which they become chrysalides; in this state they remain until July, when the perfect insects emerge from the cocoons. The moths though common are comparatively seldom seen, as they only fly at night, remaining during the day hidden among leaves, in hedges, Grass, &c. The males are generally somewhat smaller than the females; they measure from 1 in. to 1½ in. across their fully expanded wings. The antennæ of the males are much more deeply toothed than those of the females, and their bodies are more slender. The colour and markings are similar in both sexes. The general colour of this insect is a pale yellow, or tawny, or reddish yellow. On each of the four wings are two whitish transverse, somewhat curved lines, which are not quite parallel, being rather further apart at the upper margin of the wing than they are at the lower margin, the spaces between which are of a darker shade than the remainder of the wing; the fringes of the wings are white interrupted by spaces of the general colour of the wings.

The caterpillars, when fully grown, are about $1\frac{1}{2}$ in. in length; they consist of twelve joints, exclusive of the head, the first three, the sixth, seventh, eighth, ninth, and last joints, each bear a pair of legs. The head is a bluish-grey with two black spots; the body is slightly covered with hairs, down the middle of the back is a white line, on each side of which are two reddish, fawn-coloured stripes, separated from one another by a black stripe; below the second fawn-coloured stripe, on either side, is a wider, bluish band, and, below that, another fawn-coloured stripe. The chrysalis is dark brown, enclosed in a thin silken, oval cocoon, sprinkled with a fine white or yellowish powder.

S. G. S.

NOTES FROM KEW.

Stove Plants.—Even at this dull season of the year each successive visit to the stoves at Kew continues to afford fresh subjects of interest, amongst which some may fairly lay claim to novelty, whilst in others we often recognise some old favourite, such as *Columnnea Schiedeania*, long ago introduced to gardens, and found growing as an Epiphyte on trees near Misanla and other districts in Mexico. It forms a very ornamental object when planted so that it may attach itself to the trunk of a Tree Fern or any similar support; in such a position it attains from 6 ft. to 10 ft. in height. The leaves are lance-shaped with prominent reddish veins on the under surface; it produces a profusion of blossoms, which are similar in size and form to those of the well-known *Rhodochiton volubile*, the calyx being of a deep flesh colour, the long two-lipped corolla deep orange copiously spotted with red. Than the *Mysore Hexacentris* (*H. mysorensis*) few climbers are more attractive at this season, and it is particularly adapted for training to a rafter or on an umbrella-shaped trellis, as the long pendulous racemes of deep yellow blossoms are then seen to the best advantage. It is an evergreen of rapid growth and very free flowering. The variety here is named *lutea*, and as in the type the margins of the petals are of a deep red colour. The lemon-scented *Gardenia* (*G. citriflora*) is a remarkably neat and desirable shrub, growing about 2 ft. high, with small, dark green leaves, and literally covered with clusters of pure white blossoms of the size of a shilling; they emit a delicious odour, reminding one of that of Orange blossoms. A plant of such real merit is surely entitled to a place in every collection. The South African form of *Crinum ornatum* is flowering freely in the Palm-house, and makes a noble specimen. It has bold ample foliage and stout flower stems that rise 3 ft. high, and are terminated by umbels of lovely large blossoms 3 in. across, and of a delicate bluish tint. One of the finest *Bromeliads* is the drooping *Bilbergia* (*B. nutans*), a native of Tropical America, and both novel and striking. Its leaves are from 1 ft. to $1\frac{1}{2}$ ft. long, narrow and channelled. The flower stems are about $1\frac{1}{2}$ ft. long, gracefully arching in the upper part, and bearing several rosy-pink bracts from 2 in. to 3 in. long, and pointed. The flowers are $\frac{1}{2}$ in. long, narrow, of a pea-green colour, edged with deep purple. *Rhipsalis rhombica*, a native of Brazil, is a curious member of the Cactus family, with flattened branches coarsely notched at the edges, from the sinus of each of which springs a pellicled, star-like blossom of a pale yellow colour. These being produced in such large numbers in continuous succession render it well worthy of culture in the dry part of a stove. *E. crispata*, from the same country, is very similar to it, but by no means so free flowering. A few very handsome kinds of *Aloe* are now enlivening the Cactus house, the most conspicuous being *A. supralavica*, which is several feet in height, with massive glaucous leaves spreading horizontally, and dense spikes, 15 in. long, of deep orange-coloured blossoms. *A. platylepis* is of similar dimensions, but with ascending leaves and flowers of a lighter hue. The variety *lutea* bears handsome yellow flowers. *A. depranophylla* is very distinct, on account of its decumbent foliage and short, thick raceme of deep red blossoms. All these are natives of the Cape region.

Orchids.—Perhaps the handsomest of all the Dendrobies is *Dendrobium Wardianum*, here represented by finely-flowered examples. It is a very variable kind, for, even in a small number, a few well-marked forms may be detected differing from each other in the size of the flowers and clearness in the colour of the markings. Some, what resembling it in colour is the fleshy-jointed *Dendrobium* (*D. crassinode*), a very remarkable kind, on account of the knotted appearance of the stems, which sometimes attain 2 ft. in length. Like the last, it is an abundant bloomer, though the flowers are of smaller size. *D. heterocarpum*, though not so showy as either of the foregoing, is, however, equally desirable, on account of the delightful perfume exhaled by the blossoms, which are large, and of a pale primrose colour, with the lip covered with purple, velvety, dense hairs. The flowers of *D. aureum*, as here named, appear to differ from it merely

in being a shade darker in colour. These, on account of their naturally pendulous habit, are admirably suited for basket culture. The quadrangular-stemmed *Dendrobium* (*D. tetragonum*) is a very singular kind from Moreton Bay. Its stems are four-angled, and are about 1 ft. long, drooping in habit, and terminated by a pair of oval leaves, from which springs a cluster of spider-like blossoms, with narrow attenuated segments of a brown and white colour, and a small, recurved lip, white and barred with chocolate. Another cool house *Dendrobium* is *D. japonicum*, which has slender stems and flowers about 1 in. across, of a delicate bluish tint, with a blotch of purple at the base of the small, pointed lip. *Masdevallia melanopus* is a neat little species, much in the way of *M. polysticta*. It flowers in the same profusion, and, though the blossoms are smaller and of a duller hue, they are very fragrant. It, moreover, continues many weeks in perfect condition. The old *Ansellia africana*, which inhabits the western coast of Africa, and is usually found growing on the Oil Palm (*Elaeis guineensis*), is extremely handsome with its bold foliage and immense terminal panicles of blossoms, yellowish-green in colour, beautifully banded with rich brown. A small specimen of an unnamed variety of it is decidedly superior to the type, having larger flowers and the markings much brighter.

W.

NOTES OF THE WEEK.

Dendrobium lasioglossum.—This is an Orchid rarely seen but, nevertheless, it is one of the prettiest of its class. It is slender in habit, and its blossoms, which are as white as ivory, and about the same size as those of the Primrose-coloured *Dendrobium luteolum*, are produced on slender, graceful stems two or three together. We lately saw both these kinds just allied to in good condition in Mr. Smith's garden at Wimbledon.

Ficus radicans.—This makes an excellent plant for baskets, or, when grown in pots, it is very useful and effective for draping the path walls of plant-houses. It grows rapidly, and will withstand a great amount of rough usage, and is therefore well adapted for room decoration. It is a plant not very commonly met with, but it is largely grown by a few nurserymen near London, who carry out indoor decoration on an extensive scale.

Cordyline indivisa.—This old-fashioned fine foliaged plant may often be seen in the shape of small plants, but it is seldom met with in a state of development such as that in which we saw it the other day in Mr. Williams' nursery at Holloway. The plant to which we allude is from 4 ft. to 5 ft. high, and is furnished with broad, glossy, gracefully arching leaves. It is in the most robust health, and as a pot specimen is, perhaps, unequalled in the country. Large quantities of seedlings may also be found in the same nursery.

Begonia hydrocotylifolia.—This old-fashioned plant, which still ranks amongst the best of its class for winter flowering, we lately saw thriving and flowering freely on a rock-covered wall in Sir Henry Peek's garden at Wimbledon; plants of it placed in large pockets between the stones had thrown out large masses of stiff, glossy leaves, and, at the time of our visit were profusely furnished with blossoms. Associated, as is the case here, with *Ferns*, *Lycopods*, *Ficus*, and similar rock plants, these *Begonias* have a very pleasing effect, and afford a good supply of blossoms for using in a cut state.

Prunus sinensis fl.-pl.—Amongst forced decorative plants one of the prettiest at present is this double white *Prunus*, and it is a plant that requires but little heat to bring it into flower. Every shoot of last season's growth is now laden with most beautiful pearly white, double flowers, and they remain in good condition for a considerable time in a cool conservatory temperature. I find this, *Deutzia gracilis* and *Spiraea japonica* to be most useful for mixing with brightly-coloured *Azaleas* and Dutch bulbs now coming freely into bloom.—J. GROOM, *Linton*.

Flowers, Fruits, and Vegetables in Covent Garden.—Notwithstanding the severity of the weather, this market appears to be well supplied with all kinds of flowers, fruits and vegetables in season. Bouquet flowers consist of *Camellias*, paper-white *Narcissus*, white *Lilacs*, *Rosebuds*, pink and white *Pelargoniums*, *Lily of the Valley*, and *Hyacinth* pipes. The waxy white blossoms of *Lælia alba*, *L. anceps*, and *Coloquiza cristata* are also now being used largely in a cut state. Fruits, which are plentiful, consist of *Gros Colman*, *Lady Downes*, and *Muscat Grapes*, all somewhat lower in price than usual; *Pine-apples*, of fair size and quality, fetch from 8s. to 12s. each; *American Lady Apples* may be obtained at 2s. per box of about three dozen fruit; good *Newtown Pippins* are scarce, but fairly good in quality, and selected *Nonpareils* may be bought at from 1s. 6d. to

2s. per dozen; Tangierine Oranges and Pomeloes are very plentiful, and Pears of the Belle Angevine and Catilla types are very good and of immense size; a few examples of Easter Beurré of good quality may also be had. Asparagus is at present anything but good, but Seakale is excellent and moderate in price; Mushrooms (buttons) sell for 2s. per box, containing about 2 lb.; Cucumbers are fairly plentiful, but appear to have suffered from an insufficiency of heat; new Kidney Potatoes of good quality may be obtained at 1s. per lb., and inferior ones at 6s.; a few Tomatoes are offered for sale, but they are small and badly coloured; forced Rhubarb is abundant, and there is a good supply of firm white Broccoli.

The Green Park.—The plan of spoiling this Park by running short-cut walks through nearly all its remaining green spaces is being persistently carried out. Much "progress" has been made in this direction this winter in spite of the bad weather.

Primula Blushing Beauty.—This is one of the best of the double Chinese Primulas now in flower in the London nurseries. The plant is a free grower, and an abundant bloomer, its flowers being of the palest white, changing to blush, very double, and with fimbriated edges, and larger in size than those of any other double Primula. It was raised and sent out a few years ago by Messrs. Henderson, of the Wellington Nursery.

Pryal's Golden Cypress.—The editor of the "Californian Horticulturist" states that during a visit to the nurseries of A. D. Pryal, on the Temescal Creek, some four miles from Oakland, California, he saw the original tree of Pryal's Golden Cypress, which he describes as "a seedling of marked character from the well-known C. pyramidalis. The deep yellow blotches ran into the branches, and even show on the cones. The compact growth and evenly-distributed variegation make this a promising novelty."

Cologynes and Amaryllises.—These, associated, form an effective feature just now in the Pine-apple Nurseries. The former are grown in quantity in small pots, and are subjected to cool treatment, a system under which the plants assume a deep green, healthy appearance, and the pseudo-bulbs, which are large and plump, extend themselves in such a manner as to almost completely hide the pots. The Amaryllises consist of many showy named and seedling kinds, among the best of which is the crimson and white A. Hendersoni. The singular Epidendrum tridactylon is also flowering freely in one of the quaint-looking shells of the Brazil Nat. Its flowers, which are white, possess a perfume very similar to that of a Primrose.

Primulas at Forest Hill.—There is at present a fine display of Chinese Primulas in Messrs. Carter & Co.'s nursery at Forest Hill. It consists of some hundreds of well-grown plants, many of which we saw in flower in November last, and which still retain their beauty. The flowers throughout are faultless in form. Their colours consist of pure white, crimson, mauve, violet, and brick red, and many of them are producing two rows of finely fimbriated flowers. We also noticed one kind with blue flowers of large size and good form, thus showing that ere long permanent blue-flowered forms of Chinese Primulas may be expected to occur as frequently as crimson or rose.

Camellias and Orchids.—These are well cultivated in the same house in the garden of Sir H. Peck at Wimbledon. The Camellias occupy a back border of a narrow lean-to house, and are tied and pruned in, so as to form a sloping bank of glossy leaves and blossoms from the floor to the roof. The Orchids, which consist of *Cyclopoglossum*, *Oncidiums*, *Cypripediums*, *Lycastes*, &c., are grown in pots arranged on a narrow, gravel-covered stage along the front of the house next the glass, whilst from the roof are suspended noble plants of the snowy white-flowered *Cologyna cristata* growing in large, raft-like teak-wood baskets. Of *Oncidoglossum Alexandræ* and *O. Pescatori* and *Lycaste Skinneri* there is a good display, and in another house is a collection of *Dendrobiums*, which will shortly be in flower.

Lachenalia pendula.—This is grown to perfection in baskets in the gardens at Wimbledon House, where numbers of it are just coming into bloom. The baskets, which are made of wire, are round, lined with Moss, and filled with good soil. The bulbs are planted at equal distances apart in the Moss all over the baskets, and when in flower they form large balls of brilliant blossoms and deep green leaves. The bulbs are taken out yearly; the baskets are refilled with fresh soil and planted again. Abundance of water is necessary after the plants commence to grow, and this can best be supplied by immersing the basket wholly in a tank. Grown in the manner just described *Lachenalia* thrives amazingly, and are seen to better advantage than when grown in any other way, whilst for hanging either in windows, porches, or conservatories, they are both useful and attractive.

THE FRUIT GARDEN.

PRUNING AND STARTING LATE VINES.

The experience of the past year will probably arouse many Vine growers to the importance of starting Vines for producing a supply of late Grapes somewhat earlier than we have been accustomed to do, and of pruning and dressing them—where dressing is still considered necessary—in time to admit of their being started from the beginning to the middle of February. In the cultivation of late Grapes there are many points which should receive primary forethought, not the least of which is, how the best return can be produced at the least cost in fuel, which is a very heavy item in the garden expenditure of the present day. Before taking this part of the subject into consideration there are other details upon which I would like to say a word. After the Grapes are cut and carefully stored away in dry fruit rooms, the Vines should be pruned without delay; and in pruning I think a wise discretion might be exercised in many cases, not in cutting upon any particular principle or upon any mathematical calculation, but upon a system the result of experience acquired by studying the conduct of the different varieties of Grapes grown under different conditions and circumstances. There is no doubt that soil, climate, and other circumstances have a very potent effect, either one way or the other, in the production of Grapes; so also has the amount of light to which the wood of the Vine is exposed. If this important factor in Grape culture be minimised by encouraging more spurs, and consequently more leaf growth, than can be fully exposed to the direct action of sun and light, the results will—must, in fact—be less satisfactory than they otherwise would be. In pruning our late Vines this year, I have been struck with the varying conditions of growth, its character and solidity, in several varieties of Vines of more or less robust habit, where influence of sun and light had most play amongst the wood and foliage and where the spurs had not been too thickly set on the Vines. I also noticed, in strong-growing varieties like Trebbiano, where a latent eye pushed away a weakly growth which was encouraged, how solid and thoroughly ripened it was to the core, as compared with strong shoots on the same Vine from spurs on either side of it. Practically, then, pruning is an operation to be learned by experience of non-superficial character; for not only do Vines vary in habit in different soils, but the houses in which they grow also alter their condition a good deal. Vines which are grown in low, badly-ventilated houses should not be planted nearer to each other than 3 ft., and the spurs, where they are grown on the spur system, should be 18 in. apart; they should also be started into growth a month earlier than Vines which are more favourably situated in light, airy, lofty houses. Of course exceptions would occur in the case of Vines such as Lady Downes, which scalds so badly in hot weather. This variety may be grown at 2½ ft. apart, and the spurs might be allowed to grow closer, in order that the foliage might shield the berries from sudden blinks of strong sunshine. Another matter worthy of consideration in the case of vigorous-growing Vines is that they should not be too much "curbed" by stopping where there is anything like a fair opportunity of giving them headway, nor should they have over-stimulating food supplied to them while they show a disposition to grossness. Plenty of clear water at the roots will be sufficient for them, and with a long season of growth they will settle into a free-bearing state, which cannot be expected from the practice of late starting and a system of cultivation which induces soft pithy shoots. Vines are often retarded in spring, on the plea of economy; but I fear the fact is lost sight of that it takes more fuel to finish off crops in a dull, unless autumn than it would to give them an early start in the spring, to say nothing of the superiority of solar heat over the artificial warmth that can be obtained from hot-water pipes.

W. H.

SOIL FOR PINE APPLES.

THE instances Mr. Simpson mentions (p. 102) in which Pines are grown in a mixture of loam and peat, and in peat alone tell their own tale. Does Mr. Simpson mean to say that good pure loam suitable in texture is not the right soil for Pines? If not, what is the use of his trying to upset a fact by instancing a couple of exceptions? As to the shape of house for Pines, my reason for giving preference to a hip-roofed structure, as a matter of course facing south, is that it gives an opportunity of raising the back of the pit in which the plants are placed, so as to bring them all more equally near the glass than in a span-roofed house, under which conditions it is a question if they do not get as much light as in a span-roofed building, unless the latter is very narrow, and in a hip-roofed house, with a path at the back, and the centre pit as usual not coming beyond the ridge,

the plants are more, evenly elevated near the roof, and there is one indisputable advantage, that the heat is more easily kept up during cold winter weather in a hip-roofed than in a span-roofed house.—T. BAINES.

Mr. Simpson evidently does not accept Mr. Baines' statement as to fresh loam being the most suitable soil for Pines in the sense in which Mr. Baines wished it to be taken. There can be no doubt that if suitable loam can be had it is preferable to peat or ordinary loam and peat mixed. In Pine growing I have had to employ various qualities of loam, from the fine yellow fibrous loam of Staffordshire to the clayey loam of Sussex, and from the latter the results were the most satisfactory. The Sussex loam to which I refer was impregnated with iron, and the only additions made to it in potting Pines were soot and crushed bones, a compost which suited admirably, but to attempt to grow Cucumbers to perfection in this loam was impossible: the plants grew vigorous enough, but the fruit all became deformed. If suitable loam can be procured I entirely agree with Mr. Baines that it is the best soil that one can use for the growth and development of good Pine-apples.—A. HOSACK.

A SUNLESS JANUARY.

THE marked absence of sunshine has added much to the severity of the long frost. A dull time has its advantages. Plants that remain frozen by day as well as night take less hurt, as a rule, than those that undergo the dual processes of freezing and thawing every twenty-four hours. But then the absence of sunshine intensifies the cold; there is nothing to make the frost relax its hold. During bright, frosty weather the heat of the sun relaxes the grip of the frost, and thus checks its power, and penetrates through vegetable tissues or enters deeply into the ground. What power or hold the frost gains at night it partially, at least, loses by day, and hence the aggregate amount of cold is less than in a sunless time. Worse still, though the sun has hidden its face, the wind has arisen and blown from the east with unusual keenness and severity. This may be said to have completed the trials of the plants, and killed many and crippled more of them. With no sun to warm or strengthen them, it is no marvel that they bent down before the east wind and perished amid January dust, which seemed colder than driven snow or sharp particles of ice itself. Scarcely were these peculiar atmospheric conditions more destructive outside than injurious under glass; vegetation either stood still or moved on slowly and weakly. The forcers of early Grapes, Peaches, and Strawberries, have had a sorry time of it. The absence of light has never been more keenly felt in early forcing. A cultivator, in a contemporary, tells us how he moved his bees from house to house in succession to set his Peaches when in flower, but the wonder is how he enticed them to fly in the absence of sunshine and in such semi-darkness which was a mere apology for daylight. Heat alone does not make bees very lively, that is certain. No doubt if the bees can be tempted to hunt for honey in every opening flower, they would render an important service in the Peach house. It is doubtful, however, if flowers under glass are as richly stored with nectar as those in the open air. Bees inside are, as a rule, far more anxious to get out again than diligent in gathering honey. A good many of them seem to prefer battering themselves to pieces against the glass than sifting from flower to flower. So, upon the whole, I prefer a camel's-hair pencil to bees; and this and a dry atmosphere have seldom been more needful than this spring to set Peaches, Strawberries, and Vines. A good many have let the plants almost stand still rather than push them during such dull cold weather. The plants themselves seem also to have preferred resting to growing. Seldom has vegetation been so slow to start or made less progress than during December and January. With judicious management and the return of sunshine, but little time may yet be lost. Vines, especially after the start, may be pushed on at a good rate, not only without harm, but with positive benefit. Such semi-tropical plants are not accustomed to be capricious as regards growth after they start; they rush on from the break to the blossom; and we run but little risk in assisting them in this respect in our artificial arrangement if the sun only favours us with his presence.

D. T. FISHER.

Scottish Horticultural Association (February, 4).—Mr. Caie, Inverary Castle, sent a paper on this occasion which was read to the meeting, the subject being the arrangement of trees, shrubs, and climbers for pleasure grounds, leaving details to be worked out according to individual circumstances. It was recommended that before the ground was laid out or planted, a thorough conception of its capabilities should be arrived at, otherwise the ultimate effect would be marred. After mentioning how and where trees should be grouped, he named the various trees, shrubs, and climbers most suitable for giving beauty to the landscape. Mr. Burns, Kingwall, also sent a paper for the consideration of the Association,

entitled the "Acclimatisation of Plants." An animated discussion followed the reading of this paper, the opinions brought out being that plants could only be acclimatised to a very limited extent. Mr. John Clark received a first-class certificate for a new variegated, ornamental *Betula* suitable for bedding purposes. Mr. Alexander McMillan exhibited trusses of zonal *Pelargonium* and *Chrysanthemum* blooms in excellent condition for this season. Mr. Charles Buchanan exhibited three large flowers of *Clerodendron Balfourianum*, taken from a plant with forty spikes, equal to those produced in the middle of summer. It was intimated that the following were the successful competitors for the kitchen garden plans.—1st, Mr. Charles Warrick; 2nd, Mr. Webster, both in Dalkeith Gardens; equal 3rd, Richard Parker, Hutton Hall, Gainsboro'; W. H. Divers, Messrs. Veitch's nursery; and William Taylor, of 17, Frederick Street, Edinburgh. Mr. McMillan, Broadmeadows, sent a few notes on the Edinburgh weather, stating that he had 35° of frost on the 14th December, and from the 4th to 3rd February he had 620° altogether. The president gave some of his observations at Dalkeith on the same subject the most frost experienced there being on the 14th December, and amounting to 22°.

ANSWERS TO CORRESPONDENTS.

Coleogyne cristata.—How should this beautiful plant be cultivated? —A SUBSCRIBER. [The temperature of the cool end of a Cattleya house suits this plant admirably; but during winter it should be kept quite cool; indeed, when in flower, it may be removed to the drawing-room or parlour without fear of injury. It must, however, be placed in the stove again before the shoots begin to grow, or the dryness of the atmosphere may cause the growths to be stunted, and thus one season's bloom would be lost.]

Poinsettias without Stove Heat.—Will you kindly record a little more in detail your experience with Poinsettias, which are certainly amongst the most valuable of winter-blooming plants. My hopes were raised by an account in *THE GARDEN* (p. 57) of the Poinsettias at Mr. Hanbury's place near Ware. In that account there is no mention of stove heat; "a little heat" to start the plants, after which air is to be admitted freely is all the heat described as necessary. Can it be possible to grow this plant with only warm greenhouse treatment? and then keep it when in flower in a house ranging from 40° to 50°? The account from Ware made me, as I have said, hopeful, but in the following week an account of Poinsettias at Acton makes me fear that more heat is needed than I have at present seen. I have seen (p. 57) of the Poinsettias in this country (Gloucestershire) in an old-fashioned Orangerie with all the windows wide open, and no perceptible heat; but this was in the mild winter of 1877. I know that Poinsettias flower freely at Malta and at Gibraltar in the Winter, which is not there warm. An answer would, I am sure, interest many, like myself, with a large space to decorate and no actual stove heat.—C. A. B. [In order to strike cuttings of Poinsettias and grow them well, a close, warm temperature and a brisk bottom-heat are necessary, but having fairly struck the cuttings, or if you possess established plants, you might grow them successfully as described in *THE GARDEN* at the articles to which you allude. Such as are planted out during summer, when lifted in autumn require to be put in a frame or house where a close moist temperature of from 60° to 65° can be maintained, and they must for a week or so be shaded slightly from the direct rays of the sun. After that a greenhouse, in which the temperature by night does not get below 50°, will suit them, and by day it may, by the aid of sun and fire-heat, of course, be considerably raised. When fully in bloom, conservatory temperature from 45° to 50° by night and from 55° to 60° by day will suit them, and in such a temperature they will last in bloom even longer than in a higher one.—C. W. S.]

Names of Plants.—*Anon.* The bulb is *Amaryllis Belladonna*, drawn up in heat. *E. T.*—*Sedum carneum* variegatum. *J. P.*—*V. theimii viridifolia*. *M. L. D.*—1, *Begonia fuchsoides*; 2, *Succulent* of some kind, undeterminable without flowers; 3, *Libonia floribunda*.

Questions.

The White Poppy.—I hear that this is extensively grown in the south of France. As I am interested in the subject, I would feel much obliged if some of your correspondents could give me all particulars as to locality, &c., or tell me where I could get such information.—*M. Masters.*

Planting near Carriage Drives.—Will some of your correspondents oblige me with some hints for planting a green sward forming one side of a carriage drive, in Surrey, about 200 yards long, running nearly north and south? On the west side of the drive there is already a well-grown belt of forest trees. Branches in some places extend across the drive, but these could be cut back if needful. The soil is sandy loam. I thought of planting some of the choicer sorts of *Rhododendrons* at intervals, and I should be glad of a list of evergreen and deciduous shrubs suitable to fill the intervals. What also would be a good selection of trees with which to plant three clumps in the paddocks adjoining.—*DELA.*

Peach-house Paths.—I am putting up a lean-to Peach house 100 ft. long. What sort of a pathway would your correspondents recommend me to have?—*WELSHMAN.*

Soot Water.—What is the proper proportion of soot and water to use in making the liquid manure much spoken of in *THE GARDEN*?—*M. F., Clifton.*

"This is an art
Which does mend Nature: change it rather: but
This ART ITSELF IS NATURE."—Shakespeare.

NOTES ON CROCUSES.

As some little time will elapse before the publication, in a complete form, of the monograph of the genus *Crocus* which I have in preparation, I wish to record one or two points that have occurred to me in which the nomenclature of several known species will have to be modified and some additions made to the species of the genus.

In examining the *Croci* in the herbarium at the Botanic Gardens, Edinburgh, I found a set of specimens collected by Dr. G. Kirk (now consul at Zanzibar), at Renkier, Dardanelles, in March, 1856, which I have little doubt is an undescribed species. Several names have been successively attached in pencil to the specimens—Boryi, albiflorus, biflorus, and susianus—and afterwards erased, but with none of these will it agree, and the associated characters would separate it from every other known species. I propose to call it

Crocus Kirkii, coming under the division *Schizostigma* of Baker. *Limb* 12 lines to 14 lines in length by $3\frac{1}{2}$ lines to 4 lines wide, white or pale cream colour, yellow towards the throat, the outer divisions occasionally striped and feathered externally with purple, like *C. biflorus*, or faintly suffused with purplish markings.

Throat apparently unbearded, yellow.

Tube from germin to throat 2 in. to $2\frac{1}{2}$ in. long.

Stigma 7 lines high, orange, dividing towards base of anthers and immediately branched into about a dozen capillary terminations, reaching a little above the level of the anthers and resembling the stigma of *C. hymalis*.

Anthers 4 lines to 6 lines in length, on a filament 2 to 3 lines high, reaching nearly to the level of stigma.

Leaves appearing with flowers in March, and subsequently produced 20 in. or 22 in. in length in April; blade very broad and flat, 3 lines wide, with a slightly reflexed margin; central white band, narrow, and well defined; keel glabrous, very narrow, lateral channel wide and open, glaucous, traversed by five or six narrow ribs and furrows.

Corm 8 lines to 9 lines wide by 7 lines to 8 lines high.

Corm tunic of parallel fibres, resembling that of *C. aureus*; main tunic splitting up from base into strong, flat, parallel, unbranched fibres, united in parcels of three or four at apex; basal tunic of short, strong fibres, radiating from a broad, basal plate; cap membranous, produced as a bunch of flat, pointed fibres, $\frac{1}{2}$ in. to $\frac{1}{4}$ in. above summit of corm.

Basal spathe absent.

Proper spathe of two equal membranous valves, 2 in. to 3 in. in height, exceeding sheath-leaves and reaching nearly to throat.

Germin $1\frac{1}{2}$ in. to 2 in. above summit of corm, the supporting scape lengthening to 3 in. or 4 in. in April.

Sheath-leaves three, from 1 in. to 4 in. in length, the longest with a broad, expanded termination, falling short of proper spathes, and enclosing from two to three scapes.

Flowers produced in March and early in April.

Renkier, Dardanelles; gathered by Dr. G. Kirk, March and April, 1856.

Crocus aleppicus (Baker) and *C. Gaillardotii* (Boissier).—I am indebted to Professor Haussknecht, and also to M. Boissier, for specimens of a diminutive *Crocus* gathered by the former on Djebel Nabor, one hour north-west of Aleppo, in January, 1867, and on comparing it with *C. Gaillardotii*, of Boissier, from several localities in the south of Syria, I have no hesitation in concluding that they are one and the same species. The name *aleppicus* must, therefore, yield to the older name *Gaillardotii*. This species appears to be common in the south of Syria, and probably extends northward over the intervening country to Aleppo. It must not be associated with *C. hymalis*, of Palestine, from which it is distinguishable by its compact fibred corm tunic; that of *hymalis* being membranous without distinct fibres. *C. Gaillardotii* is a much smaller plant than *C. hymalis*.

C. vitellinus and *C. syriacus*.—Although somewhat different in aspect, the latter being a smaller plant, they must, I think, be looked

upon respectively as the orange or bronzed forms of one species. I have been favoured by Professor Haussknecht with specimens of the little striped *Crocus* from Aleppo (*C. syriacus*, of Herbert and Baker) and have also in cultivation the Beyrout plant, between which I can detect no difference of any specific value; indeed the Beyrout and Saïda form, which is rather larger than that from Aleppo, occasionally occurs with bronzed flowers, and various collectors who have liberally supplied herbaria with specimens from Northern Palestine have labelled them indiscriminately *syriacus* and *vitellinus*. This is a midwinter flowering species and must not, I think, be associated with the bronzed *Crocus* from near Smyrna.

C. Balanensis, discovered by Balansa on the hippurite limestone plateau above Smyrna, where I have also gathered it. Though growing at a low level, from 500 ft. to 600 ft. in altitude, it is a late vernal species, and flowers at least three months later than *C. vitellinus*, from which it differs by its very broad leaves and by other characters.

C. Orsinii (Parlatore).—I had a long, unsuccessful hunt for this species in October, 1877, having, as I afterwards ascertained, gone too high up on Monte di Fiori, near Ascoli, Italy. I have recently been favoured by Professor Cesati with specimens gathered by Tenore in 1830, and have also seen Orsinii's specimens of a year later from the same locality, gathered on the south-east flank of the mountain, at altitudes of from 2000 ft. to 3200 ft. I find we have here a form almost precisely identical with the garden Saffron, quite undistinguishable from it, except that the stigma is a little shorter; indeed, Tenore labelled his Monte di Fiori specimens "*C. sativus, sauvage*," and, but for Parlatore's subsequent name of Orsinii having been applied to this plant, the vexed question of the wild origin of the garden Saffron need not have remained open.

C. Pallasii, from Dalmatia, and *C. Thomasii*, from South Italy, must, I think, be united as one species. A careful comparison of the specimens at Kew, and in the Florence Herbarium, permit of no other conclusion, which has been hinted at long ago by several writers, including Visiani, Nyman, and Baker. I have in cultivation this plant from the neighbourhood of Patras in the Morea. *C. visianicus*, of Herbert, *C. campestris*, of Pallas, and *C. hybernus*, of Fridwaldsky, are probably also identical with *C. Pallasii*.

C. karduchorum (Kotschy).—"In jugis inter Müküs et Scherwan Karduchia, 6000 ft. 27th Sept., 1859." In specimens thus labelled in the Kew Herbarium the long corm (as distinguished from the exceptionally flat corm of *C. zonatus*, Gay) and dense membranous corm tunic are characters that would, *prima facie*, separate it from Gay's *Crocus zonatus*, the only species near to it; but the flowers of the Kew specimens are insufficient to draw up a description from. As the plant probably exists in other herbaria, I should be much obliged by the loan of any specimens exhibiting the stigma and stamens.

C. cilicicus (Kotschy) appears to be abundant in the Cilician Taurus, and has been, from time to time gathered by various collectors, and described under several names, which it will be convenient to suppress. *C. cancellatus* var. *Kotschyanus* of Herbert, *C. pylarum cilicicum* of J. Gay, and "new species allied to cancellatus," gathered by Balansa in the Cilician Taurus, appear to be identical with *C. cilicicus*, and all of these Baker places under the species *cancellatus*. I cannot take exception to this view, but as the bright blue oblongo-lanceolate limb, which is narrower than in the ordinary forms of cancellatus, seems to be a constant character of the Cilician plant, I think it may be properly and conveniently made a sub-species of cancellatus.

The name *Kotschyanus* having been applied for some years to two very dissimilar species, viz., to the cancellate *Crocus* of the Taurus and to Gay's *C. zonatus*, it will be best to discard it altogether, and retain the name of *cilicicus* for the one and *zonatus* for the other.

One other error respecting two Spanish species I wish to suggest a correction for; viz., the confounding of *C. nudiflorus* with *C. serotinus* in the records of numerous Spanish habitats. As far as my own observations go, *C. nudiflorus* does not extend south of the chain of the Pyrenees and Asturias, and in none of the specimens from the alleged habitats of *C. nudiflorus* in Central Spain, can I recognise anything but *C. serotinus*. I have received from Gijón, in North Spain, bulbs of Herbert's *C. asturicus*, but this cannot be admitted as an ally of *C. nudiflorus*, and appears to be merely a form of *serotinus*, which is a later flowering species of smaller stature, the leaves of which are autumnal, just appearing with, and immediately after the flowers. The stoliferous reproduction of the corm, which is so marked a feature in *C. nudiflorus*, is absent in all the specimens I have examined from the alleged Spanish habitats of *C. nudiflorus*. I do not say that *C. nudiflorus* may not occur here and there south of the Pyrenean chain, but the recorded habitats and the specimens

thus named by many authors and collectors, are unquestionably forms of *C. serotinus* of Salisbury.

C. etruscus (Parlatore).—I had the good fortune, in company with my friend, Mr. S. Sommer, of Florence, to refine this plant in the Tuscan Maremma in the spring of 1876, and we had no hesitation in agreeing that it was a thoroughly distinct and well-marked species. Its affinities, however, are not, as had been supposed, with *C. reticulatus*, but with the group of Italian and Corsican species, including *versicolor*, *Imperati*, *suaveolens*, *corsicus*, and *minimus*. The strongly reticulated corm coat resembling that of *C. reticulatus*, is merely an instance of the singular absence of natural grouping of the character of individual organs, which is such an obvious feature of the genus.

C. minimus (D. C.) = **C. insularis** of Gay; and **C. corsicus**.—As I have already published descriptions of the two very distinct species of *Crocus* occurring in Corsica and Sardinia, which have hitherto been lumped under the name of *minimus*, I will here merely point out that the smaller of the two, *C. minimus*, which is confined to low elevations near the coast line, is distinguished by its small, dark purple flower, yellow or pale orange stigma much exceeding the anthers, and by its corm tunio, consisting of parallel fibres; and the larger, *C. Corsicus* (which is confined to the mountains, and I believe does not occur below a level of 2000 ft.) by its pale purple or lilac flowers, with a distinct buff or cream-coloured coat on the outside of the three outer limbs, its much larger stature, its short orange-scarlet stigma, and its finely reticulated corm coat.

C. peloponnesiacus (Orphanides).—A good deal of obscurity and doubt hangs over this species, and, if really distinct, its affinity lies with *C. hadraticus*. The only point of difference, according to the published description, is that *C. peloponnesiacus* flowers before the leaves appear, and that in *hadraticus* the leaves and flowers are contemporaneous. Cultivators of *Crocuses* know that in many cases this is only a question of degree, and it may be that the original description of the supposed new *Crocus* was drawn up from a specimen of *C. hadraticus* in which the leaves were late in being produced. In a specimen of supposed *C. peloponnesiacus* recently sent me from the neighbourhood of Patras by Professor de Heldreich, of Athens, I can detect no character that would separate it from *C. hadraticus*. *C. hadraticus* is very variable; in many cases the flowers are pure white; in the Albanian plant white with a purple blotch at the base of the limb; and in the Santa Maura form (*C. chrysobolonicus*) the throat, which is of a bright golden-yellow, is externally veined with chocolate.

I would here notice that a plant has been extensively distributed as *C. peloponnesiacus*, which is merely one of the numerous varieties of *C. cancellatus*, at once distinguishable by its corm tunio of strong oblong-reticulate fibres, that of the true *C. hadraticus* consisting of fine silky reticulations like the well-known corm tunio of *C. sativus*, to which *C. hadraticus* is allied.

C. Boryi (Gay) = *C. lavigatus* (Bory et Chaub.), *C. Tourneforti* - *C. marathonisius* (Heldreich), and *C. orphanidesi* (Hooker). In this group, the distinction between *C. Boryi* and *C. Tourneforti* was well understood by the late Dean Herbert, but as these two species often grow in their native habitats closely intermingled, the bulbs have in later years been confounded in a confused way in English collections.

This section includes two well-marked species, *C. Boryi* or *lavigatus*, distinguished by its hard, cartilaginous corm tunio, like a thin Hazel-nut shell, splitting up at the base into a series of vandike terminations, the successive tunies underlying each other and lasting for many years as a series of super-imposed imbrications over the Pear-shaped corm; also by its comparatively short, erect, much-branched stigma, generally yellow, rarely orange, and by the symmetrical feathered markings of the limb resembling those of *Crocus biflorus*.

C. Tourneforti, by its softer fibro-membranous tunio, its long, fragile-branched, orange stigma, the lax divisions of which bend over, and by its self-coloured limb rarely marked, except with a few unbranched lines.

C. marathonisius, of Heldreich, and *C. Orphanidesi*, of Hooker, are closely allied to *Tourneforti* and not to *Boryi*. *Marathonisius* is, I believe, invariably white; *Tourneforti* and *Boryi* also vary with white flowers, and the three white forms placed side by side are not a little perplexing. White *Boryi* and white *Tourneforti* are, however, distinguishable by their corm tunies and stigmas, and white *marathonisius* by its extremely short and fragile stigma generally reduced to three fine thread-like terminations. Professor de Heldreich assures me that this is a constant character, and it is invariable in the specimens at Kew and those both fresh and dried received from Athens; but the aspect of this stigma allies *C. marathonisius* with *C. Tourneforti* and not with *Boryi*.

The white autumnal *Crocus*, common in Corfu, is probably the white form of *C. Tourneforti*; the leaves of *C. Tourneforti* and *marathonisius* are usually both longer and narrower than those of *C. Boryi*.

Whilst writing, I am told of a gay lilac and yellow *Crocus* having been observed near the melting snow high up on Lebanon on the 15th of May. As no late vernal species is known in Syria, what can it be? and will some tourist who visits Lebanon set this question at rest by transmitting some roots to English gardens? It was seen going from Baalbeck to the Cedars over the high pass of Muckmel, on the eastern side of the range near the path leading from Ainata on the east, to the Cedars on the west, close to the snow, and flowering amongst the melting snow.

I have also received from Mr. Barr fresh specimens of an unfamiliar *Crocus*, flowered from roots dug up by Mr. Llewelyn on sandy ground near the lighthouse at Biarritz. It has a lilac, self-coloured limb, bright orange unbearded throat, very long orange stigma branched from near summit of anthers, short, pale, lemon-coloured anthers, very broad leaves with a square keel and a double proper spathe; the corm I have not seen. I believe no *Crocus* is known from that district except *nudiflorus*, which is an early autumnal species, and *vernus*, which occurs in the Pyrenees; with neither of these will it at all agree.

Benthall Hall, Broseley.

GEORGE MAW, F.L.S.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Hardiness of Tuberos-rooted Begonias.—Having a quantity of these in open borders wholly without protection, on examination to-day (Feb. 8) I was gratified to find from present appearances that they have not received the least injury. Ours is a light soil with a dry, gravelly sub-soil, which may account for the safety of the tubers. It could hardly have been hoped that in clayey heavy soils they would have survived the late severe weather.—W. H.

Finderne's Flowers.—In THE GARDEN for January 25 (p. 75) the story is told of Sir Bernard Burke and his visit to the village of Finderne, in Derbyshire, in search of records of the ancient family of Finderne. The last of the Findernes married an ancestor of mine, and I am directly descended from her. I claim, therefore, to be interested both in Finderne, the Findernes, and Finderne's flowers. A few years ago I took some pains to find out to what species these flowers belonged. My friend, the Rev. B. Spilsbury, the present incumbent of Finderne, dug up some of Finderne's flowers from the site of the old Hall, and planted them in his garden, and they produced *Narcissus* poeticus. Whether or not *N. poeticus* grows in any part of Palestine I cannot say, but whether or not this is the plant which my maternal ancestor, Sir Geoffrey Finderne, brought home from the wars I do not presume to decide, but there is no question that the plant now known in the village of Finderne as Finderne's flowers is *Narcissus poeticus*.—H. HARPER CREWE, Drayton-Beauchamp Rectory, Tring.

Plants Injured by the Late Frost.—Now that the thaw is complete I have made a careful survey of the injurious effects which frost has had on plants here (North Hants), and the following is the result:—Common Laurels are slightly browned at the tips of the shoots, the flower buds of *Laurustinus* are killed, but otherwise they are uninjured. In the case of *Arbutus Unedo* the points of the shoots are browned, and some of the finer hybrid varieties of *Rhododendrons* have had their flower buds frozen through. All other evergreen shrubs and Conifers show no signs of the severity of the winter through which they have passed. *Eucalyptus globulus* has been killed; some of the stronger plants may break from the ground line, but that, I think, is doubtful. *Phormium tenax* has suffered severely, and even those that were protected can hardly be expected to recover. *Arundinaria falcata* is killed to the ground, but the roots seem uninjured. Some of the older leaves of *Chamaecyparis Fortunei* are damaged, but otherwise the plants are not hurt. Of *Dracena australis* several plants which have weathered the last few winters are hopelessly injured. *Arundo conspicua* and the common Pampas Grass are also much browned. Stocks, Wallflowers, and Pentstemons are killed wholesale, and even some of the *Antirrhinum* have succumbed. *Echeverias* are all killed, and some of the hardiest Saxifrages have suffered severely; such as *S. napolensis* and *S. rosularis* will hardly recover. I suspect the repeated thawings, so soon followed by keen frosts, are the main cause of these being injured.—W. W.

— You will have long lists of killed and wounded by the late severe and continued frosts. I am happy to be able to record two rather unexpected escapes—a large pan of *Sarcocolla purpurea* (the North American Pitcher-plant), standing on the Wilson raft in a

THE INDOOR GARDEN.

ACHIMENES AS BASKET PLANTS.

To amateurs and others whose means of plant accommodation is but limited, there is a great gain in growing plants that have tuberous roots; inasmuch as almost as soon as the majority of them go out of flower they require no further care, and may be wintered anywhere under stages or on back shelves, provided the soil containing them does not catch drip, or in any way become too wet and cold for their safety. Amongst others that admit of the above named treatment, none are more showy and useful or afford such a variety of colour and form of flowers, as the different kinds of *Achimenes*, the habit of which is such as to render them equally suitable for growing in pots or baskets, although it is, perhaps, in the latter way they show themselves off to the best advantage. In order to prepare them for this purpose, it is a good plan to start them first in pans of leaf-mould or finely-sifted peat, from either of which they lift readily and transplant with large balls, and may then be distributed regularly to furnish the baskets. The latter made with wires about $1\frac{1}{2}$ in. apart answer the purpose well, as between the heads of the plants may be thrust as the filling up proceeds. The quickest way, however, is first to line the basket with Moss, and then put in the soil, when, by making holes around the sides, the plants can be put into them at regular distances apart, and all made complete in a very short time. When this is done they should be hung in a house where they can get plenty of moisture and be syringed for a week or two to give them a start, after which, with a temperature varying between 60° and 70° , they make rapid progress and soon become covered with bloom. It should be borne in mind that *Achimenes* are shade-loving plants, and, therefore, the situation chosen for them should be where the sun does not strike them during the heat of the day, otherwise the leaves become blistered and the growth hard and stunted, which greatly detracts from their usually healthy appearance. The great fault with *Achimenes* in pots generally is that, owing to so many being grown together, they have a weedy look through being drawn up and having such small flowers, most of which are buried amongst the foliage instead of being set off by it. It is on this account that small pots of 6 in. or 8 in. in diameter always look better than pans containing large masses, and, besides this, they are altogether more handy and useful for decorative purposes; such sizes suit windows, greenhouses, and vases well where others would be quite out of character.

The number of tubers or plants which each pot should contain will depend on the sort, some being stronger than others and of a more branching habit; but for the generality of them it may be roughly stated that from five to ten are ample, as, when they have room, they send out many stems, to induce which it is always well to nip out the top of the first shoot formed when about 4 in. high. If it be desired to increase the stock of any new or scarce kind by leaving them to grow a little longer before they are pinched back, the tips removed in that operation may be used for cuttings, and if put in in moist heat, under a glass or in any close place, they will soon strike root and make fine flowering plants by the autumn; but in all cases where propagating is done in this way, it must be done early, or there will not be time for tubers to be formed. This is how many fail in keeping up a good stock; *Achimenes* have much of this work to do after they have done blooming, but instead of being assisted they are often set aside and allowed to take their chance, when the tops must of necessity die away prematurely. Instead of this, the right course to pursue is to place them in any frame or pit where they can have shade and be sprinkled overhead and shut up early till they show signs of ripening off naturally. If treated in this way, the soil when examined will be found to contain a rich harvest of fully-grown tubers that will keep plump and sound, instead of rotting away in the winter. The best way to preserve them is not to disturb them till they are wanted for starting, as they never do so well as when left embedded just where they grew, the conditions there being more suitable than those to which they are subjected when packed away in bags or buried in sand. To

tank on which were 3 in. in thickness of ice, is quite uninjured; a strong plant of *Abelia rnepestis*, in an exposed position on the roof-work, has only the tops of the shoots cut. How the spring flowers have burst into bloom! it is like the descriptions of the northern springs. Snowflakes, Winter Acornites, and hardy *Cyclamens* came up and were out in three days.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

Higheclere Pink.—This is one of the best rich crimson scarlet Pinks we have for borders. It keeps long in bloom, and it is equally good for forcing as for out-door decoration. Some plants of it struck last spring are just now coming into bloom, and promise to produce flowers in abundance.—J. C. F.

Stem-roots a Protection to Lily Bulbs.—I made an interesting discovery a day or two ago, which, I think, proves clearly, at least, one most useful property of the stem-roots of *Lilium auratum*. On examining some bulbs of one of the best varieties of that Lily that were not planted until the beginning of April last year, but which, nevertheless, grew strongly and flowered well, I found that these bulbs were perceptibly larger than when they were planted, and that the mass of stem-roots (dead, of course) was like a thick wig just over the bulb, protecting it most thoroughly from the soaking rains that had fallen a day or two previously; in fact the top of the bulb was as dry and comfortable as if it had been in a frame.—T. SMITH, *Newry.*

Carpeting Bulb Beds.—Allow me to add to the list of suitable plants for this purpose (p. 96) two more, viz., *Hypericum reptans* and *Erythraea diffusa*, both of which grow quite close to the soil, like a *Selaginella*, and make a perfectly green carpet, especially well suited for such bulbs as *Colchicums*, which do not produce any leaves. The former (*H. reptans*) is new to cultivation, its introduction being due to Mr. Elwes. Its flowers, which appear in large numbers late in autumn, are yellow and as large as a shilling. It is a native of Sikkim, and it has withstood this severe winter very well, although only planted out late last summer. The foliage, which is dense, has become brown just now, but the branchlets are fresh, and will, when they begin to grow, soon assume a better appearance. *Erythraea diffusa* has been regarded as a biennial, and rather tender, being a native of California; but it is a perennial, and I find it also to be very hardy; its foliage has remained all winter bright green, and it flowers abundantly in July, each branchlet producing one flower, of a beautiful dark rose colour, and as large as a sixpence. Seeds of both of these plants must be sown early, and the young seedlings should be pricked out 2 in. apart into pans, and planted out in autumn, or, better still, in the spring of the second year.—MAX LEICHTLIN, *Baden-Baden.*

Large-leaved Saxifrages.—If "W. D." (p. 112) wants a large-leaved Saxifrage he had better procure *S. crassifolia*, which has foliage about as large as that of a small-sized Cabbage Lettuce, and of the same shape, too. Many years ago I used this Saxifrage for spring and winter decoration of the flower beds, and found it an effective plant, the large, bright green leaves looking well in mid-winter, while its large spikes of flowers of a beautiful mauve colour were equally telling in spring; its only defect was that it was rather late in flowering. It is a very old plant, and may usually be met with where old plants are patronised. I have been told that there is a more recent one, of the same character and habit, that flowers some what earlier, but I am not acquainted with it. I have been told that *S. oppositifolia* is found wild on the Cumberland Hills, but I never had the good fortune to find it there, although one of the Moss-leaved species (*S. caespitosa*) was plentiful enough. I have always looked upon the best forms of our garden Moss Saxifrages as being mere varieties, not deserving a distinct specific name, but I have for some years grown one under the name of *S. Standishi*, which presents a dense, tufty mass of foliage of the brightest green all the year round, unless when in summer its faded flower stems give it a brown hue in the sun. In its native habitat it delights in moisture, while, I believe, London Pride likes a dry situation, and I have seen it thrive pretty well under trees and shrubs where nothing else would grow. In such places it may be easily mistaken for a native plant, but I expect that when duly inquired into it will be found to be merely the outcast of some garden. A pretty flowering Saxifrage is often found on lawns and in meadow fields called *S. granulata*, the double form of which is one of the greatest ornaments of our gardens, but the single form is also pretty, while *S. oppositifolia* is certainly one of the very prettiest of our British plants, and when in a cultivated form it resembles some of the dwarf Phloxes. *S. crassifolia* is not British, but it is highly deserving of cultivation, and a good-sized tuft of it is at all times an interesting object, especially in the wild garden.—A RETIRED GARDENER.

grow *Achimenes* well, the pots should be thoroughly drained, as all through the summer they require abundant supplies of water, but it is essential for their welfare that it passes freely away, for anything approaching a stagnant state of the soil is sure to throw them out of health. Nothing answers better for *Achimenes* than a mixture consisting of about equal parts of loam and peat, used in a somewhat rough state, and to this should be added a good sprinkling of sharp sand so as to render the whole porous. After May they grow well in any ordinary frame, kept shaded and shut up early, but till then they must have artificial heat to get them along. Except greenfly, *Achimenes* are not subject to insects, and these pests can easily be got rid of by fumigation, which should be done cautiously, as it does not take much to injure the tender foliage. S. D.

EVERGREENS IN POTS FOR WINTER DECORATION.

VERDURE of any kind in winter is always welcome. At Christmas time we decorate our apartments, churches, &c., with branches of evergreens, which impart an air of cheerfulness and warmth. In countries in which the winters are severe all kinds of evergreens are held in high estimation, and are extensively grown in pots and tubs for winter decoration. In this country there are many situations in which evergreen shrubs in pots would be peculiarly acceptable. Into winter gardens, unheated corridors, balconies, &c., they might be often introduced with advantage, and many a bare spot would thus be rendered bright and pleasant to the eye. There is a good choice of subjects for this purpose, many of our finer forms of Conifers being, owing to their neat, compact growth, especially suited for pot culture. Some of them, indeed, appear to succeed rather better in this way than when in the open ground, that is provided they receive that amount of care which is needful to preserve them in health. Although evergreens are tenacious of life, and are sometimes tardy in showing the effects of neglect, yet they are none the less susceptible of injury, and it is noticeable that, unlike many forms of vegetation, if they once experience a serious check they never recover their pristine vigour; they lose that fresh appearance which distinguishes them under favourable conditions.

The best time for potting these plants is early in October when the growth has ceased and the roots yet fairly active. Choose compact, bushy, well-formed specimens and put them in pots which will just contain their roots, using soil of a somewhat heavy character and pressing it well in around the roots; if loosely potted the plants are liable to get displaced before they become well established, in which case they seldom remain long in good condition. When potted they may be placed in some sheltered position until they are removed to their winter quarters; when destined to remain during the winter months in exposed situations, such as on balconies or window ledges, they must never be allowed to stand dry, and in very hard frosts, or when accompanied by drying winds, they should be placed under shelter. Amongst subjects suitable for this purpose, *Thuja aurea* and *Retinospora eriocides* may be mentioned as worthy of special attention; they are neat as regards growth, and bear exposure very well; *Cupressus macrocarpa* and *Lawsoniana*, *Thuja plicatula* and *Lobbi*, *Cryptomeria elegans*, *Aucubas*, both plain and variegated, golden and silver variegated *Hollies*, and *Buxus balearica*, are some of the most trustworthy plants for this purpose. The variegated varieties of *Euconymus* make charming pot plants and contrast effectively with the more sombre-hued kinds. The *Euconymuses* are much more satisfactory when they get the benefit of a little shelter during hard frosts; they do not appear to possess the same powers of resistance as the type, but become brown and disfigured and lose their terminal shoots in severe weather. This disfigurement has been especially noticeable this season; plants in open places have had their beauty quite spoiled, whilst those enjoying the shelter of a wall have escaped comparatively unharmed. The *Laurostimus* makes a pretty pot plant, and will, when placed in a winter garden or corridor, open its pleasing flowers considerably earlier than when in the open air. *Viburnum Awafiki*, *Pittosporum Tobira*, *Osmanthus ilicifolius*, and the broad and small-leaved *Myrtles* should all

be grown. By the middle of March they should be removed from their winter quarters into the open air, placing them where they may for a time get the benefit of a little shelter. Eventually they should be plunged in the open ground and kept well watered in hot weather. Beyond this little attention they will require no other care, and may thus be kept in good condition for years in comparatively small pots. Every year a few plants should be potted to take the place of those which may have outgrown the limits assigned to them, which latter will be found useful for planting out in the open air.

J. CORNHILL.

DECIDUOUS CALANTHES IN SMALL POTS.

WHAT has appeared in THE GARDEN about the fine growth made by these plants at Messrs. Veitch's is quite correct, as I can confirm from having seen them. Grown as at the Chelsea establishment one pseudo-bulb or so in a pot they do not need a large one, and by the use of shallow pans their weight is reduced, but any one conversant with the management of these plants can perceive, at a glance, that the small pans which they occupy is not the cause of their well-doing, but their being hung up close to the glass roof during the time when they make their growth, which enables them to get plenty of light. I have grown these *Calanthes* with even larger pseudo-bulbs than those at Messrs. Veitch's, several together in 10-in. or 11-in. pots; they also were hung up over the paths of the house. When potting, a small pot or pan is no doubt better than a large one, as these, in common with all other plants, are better not overpotted. The largest and altogether the best *Calanthes* of this section which I ever saw were grown some years since by Mr. Hubberstey, now at Bridge Hall, Bury, Lancashire. They were grown in proportionately good-sized pots, and hung up close to the roof. Mr. Hubberstey has recently grown *C. Veitchi* to such perfection that the pseudo-bulbs weighed sixteen ounces each. The advantage of cultivating these plants in a way that admits of their attaining a large size, is that the amount of flower and length of time during which the individual spikes will keep on blooming are commensurate with the strength and size of the bulbs. The very strongest will often push up a flower spike from each side of the base, and one or two from near the top as well. They will grow to a large size in almost any description of soil if not too adhesive, provided they are kept during the whole of the growing season where they will receive a maximum amount of light, with just sufficient shade to prevent the sun from injuring their leaves. In such a position they require to be freely supplied with water during active growth. Whilst flowering they need not be hung up, but may be placed where they can be best seen. They are amongst the easiest of all *Orchids* to grow, and equalled by very few in usefulness, either as decorative plants in bloom, or for furnishing cut flowers. Every individual blossom can be mounted in bouquet making, and the spikes (which should not be cut until the terminal blooms are nearly all expanded) will last in a room for a fortnight. Ever since I have been acquainted with these *Calanthes*, now some twenty-five years, I have urged every one to grow them who has a warm stove, in which they will succeed just as well as in an *Orchid* house, if there be enough heat and moisture at command. These they must have, in order to grow them well: but there is one peculiarity connected with them not generally known, and that is, that even when they have done flowering, and the whole of their leaves and roots are quite dead, as is their nature, the pseudo-bulbs must still be kept in a stove temperature, as it is during this time, that the growth buds for the ensuing year are being developed ready to start into activity. When well cared for they increase so rapidly that a stock is soon got up. I began with the red and yellow-eyed varieties of *C. vestita* when they were still dear. A couple of pseudo-bulbs, no larger than Walnuts, bought at Stevens's for a guinea and a half each, and carried home in my waistcoat pocket, soon made progeny enough to fill when in flower a good portion of a side stage in the stove, and from these I cut freely every day for three months. Their elegant drooping spikes are equal to anything I can think of for March stands, vases, and similar devices. T. BAINES.

ECHINOCACTUS UNGUISPINUS.

THIS is one of the rarest of the genus, and one that is most combative in its nature, having no respect even for the person of its owner. It is a plant that requires great care as regards watering, as it is very apt to rot; it is, therefore, best to keep it dry during the whole of the time from October to April. It flowers freely in June and July, producing good-sized yellowish-white blossoms. Such Echinocacti as this are best on their own roots, for if put on strong stocks they are apt to die off. In the case of the species under notice the central spine only is hooked, and all the spines when young are black. It is a plant which might be mistaken for a Mammillaria, but as all the Mammillarias flower from the axils of the mammae and the Echinocacti from the apex of the tubercule, just above the sets of spines, the distinction can soon be discovered. As will

Echinocactus unguispinus.

be seen by the annexed woodcut, the plant is erect in habit, and the epiderme is dark green. It is, in short, very distinct from all other Echinocacti.

J. CROUCHER.

Sudbury House, Hammersmith.

WINDOW PLANTS AND THE FROST.

THE winter in this neighbourhood has been remarkable rather for its length than for its absolute severity. But already many complaints have reached me of great losses among window plants, and those who have only small unheated or imperfectly heated structures in which to grow and keep their plants, have lost most of their Pelargoniums and other plants of a like tender character. Fuchsias no doubt are safe; they may probably die down to the base, but unless they are in very small pots, and very much exposed and the soil kept too damp, they will break again from the bottom close to the soil, but the old tops should not be cut back yet; wait awhile till the buds are pushing, and then cut down close to where new life is visible, which will probably be at that part of the plant technically called the collar, the point where the soil and the atmosphere meet. Tuberosus Begonias will be found exceedingly useful window plants for summer and autumn blooming; being of rather

a succulent nature, the dry air of a living-room will not have so injurious an effect upon them as it has upon many plants commonly grown in windows. At the approach of winter the tubers can be stowed away in pots, in any cool place, where they do not become quite dust dry. I have seen them wintered safely, by laying the pots on their sides in the open air, covering them over with ashes, and thatching the heap with straw to throw off the wet; in fact, this is a better plan than keeping them in greenhouses, exposed to alternations of dampness and dryness, which in most peoples' hands are almost inseparable from wintering them in a house where fire-heat is applied.

Few people seem to realise the protection there is in common brown paper, or the ordinary paper on which newspapers are printed. In a fairly well constructed dwelling house, if the plants be taken from the windows in the evening, placed in a corner near the fireplace free from draught, with a newspaper thrown over them, they would generally be safe; but only the most patient and thoughtful are capable of following out any such plan to the end. I have known cases in which the greatest pains have been taken to protect the plants for a time, and then perhaps on some particularly sharp night they have been forgotten, the whole previous trouble thus counting for nothing. As soon as it can be clearly seen which plants are really dead and which are not, those that have perished should be thrown out, and the pots washed ready for their next occupants.

The time is now rapidly approaching when seeds may be sown, and offsets and cuttings rooted to take the place of those plants that are lost. Amongst seeds that may be sown now in some of the empty pots, are those of Sweet Peas, which will be available for either the inside or the outside of the window. Sow about twenty Peas in a 5-in. pot. They may stand anywhere till the green tops appear above the soil; then they must occupy a position in a light, sunny window, as without plenty of light they will grow too weakly to flower well. If the pots could be suspended in a light window, as I have sometimes seen them, and the Peas encouraged to flow over the top of the pot as they progress, aiding them a little whenever the tendrils seem inclined to disarrange the proper spreading of the shoots, they will have a very pretty effect by-and-by. They will require plenty of water and a small quantity of some artificial stimulant, such as Gould's compound or Standen's manure. Outside the windows they may be planted in boxes, and either be suffered to hang down or be trained up. Anyone having a flower border may fill their empty pots with various plants from that source. Many hardy plants are well worth potting up in autumn and making a special feature of, without any reference to losses or deaths of other plants from severe weather. Hardy Primroses of the common type in various colours are now in bloom in a cold house; so are Polyantheses, and Alpine Auriculas are, in some instances showing their trusses, and such things at this season are more capable of giving pleasure than half dead and withered specimens of Pelargoniums, &c. They should be potted not later than September, and be set on the north side of a wall or fence, and well supplied with water. In November plunge the pots in coal ashes, and if severe frost sets in before they are required for the windows scatter a little dry litter over them, or a few evergreen branches laid over them will suffice. Bulbs of all kinds may be potted up for windows, and if that operation be carefully done they will experience no check. I have lifted clumps when in bloom and potted them without injury, and they may be returned to the border when their flowering season is over.

Of hardy shrubs, especially evergreen kinds, more use might be made for the decoration of windows, both inside and out, than has hitherto been done. One now and then comes across a window, like an oasis in the desert, where a special feature is made of them, serving to show how bright a window may be made with plants that are virtually frost proof. All the Barberries are adapted for pot culture, the dust easily washes from their hard, glossy foliage, and they continue in good health, if well supplied with water, for a long time. I know many plants that have been in use for several years, plunged outside in summer and brought indoors again in winter. Amongst them are Laurustinus, Aucubas, Euonymuses, &c. In fact, there is no lack of materials where the necessary time and

thought can be given to the subject, and the expense is not great in the case of those who attend to their wants themselves.

E. HOBDAY.

AN AMATEUR'S GREENHOUSE.

It strikes me sometimes that those able writers who give us such excellent directions as to how greenhouses are to be managed, what plants are to be in flower, and how they are to be made to look gay at all seasons, shoot over the heads of a great many people. They have charge of places, where, I will not say unlimited means are at their disposal—for no one has that—but where expense is little thought of, plenty of hands are employed, and the difficulties of a shallow purse and crippled space are “unknown quantities.” They are somewhat like the poor Queen Marie Antoinette, who wondered the people could be in want when such good cheesecakes could be had; or that illustrious Duke of our own country who suggested, at the time of the Irish famine, what a good thing curry powder would be to the destitute—“a pinch of it would be so warming!” They knew not the status of the people whom they really wished to benefit. Now, it is no disparagement to the overseer of a garden with its range of stoves, greenhouses, pits, &c., that he cannot understand the struggles for existence of the owner of, it may be, one greenhouse and a few garden frames. It is more his good fortune that he is in the midst of such an Eldorado of gardening wealth, rather than in the poor little surroundings of the suburban villa or the country parsonage. Now, I happen to have a great love for a garden, but I have also a somewhat slender purse; and, as I have for a decade of years had a good deal of enjoyment out of my greenhouse (for I have only one), it may be that my experience, taken from a lower level, may be of interest to many similarly situated. For their benefit I will detail my experience.

Let me say, then, what my object is; I am fond of having flowers in my sitting room. I have, too, a *placens uxor* who is apt at arranging them, but who would be the reverse of *placens* if she were not regularly supplied with them. My object then is, during the winter, spring, and early summer months, before there is a copious supply of outdoor blossoms, to be able to gather a few flowers to add to the foliage which is always obtainable.

To attain this, I have one greenhouse, or rather two joined together. The upper one is a span roof, 20 ft. in length, 12 ft. wide, and 11 ft. high. The lower one is a lean-to, 13 ft. long. This lower one has in it a couple of Vines (Black Hamburgs), so that it can only be used for certain odd purposes which I will detail, and not for growing plants. To heat it, I have a common fireplace and drain pipes. Of this more presently. The centre walk of the house is formed of battens 3 in. wide, with spaces between, under which I can stow away, out of sight, Lachenalias, Tropæolums, and such like plants, when they have done their duty. The stages are on each side, level, 4 ft. 6 in. wide, composed in the same way of battens, instead of shelves, leaving clear spaces between them for the water to run down. As they are some feet from the ground, there is room underneath where I can stand at times Vallottas, and other plants which are going to rest. Over the centre path I have a shelf, which runs down two-thirds of the house, and on this I place some square boxes with cuttings of Pelargoniums for putting out in the summer. I do not “go in” for bedding out, and these are enough for adding to the herbaceous plants in the borders, while quite at the end there is a small shelf, somewhat lower than the stage, where I can place one or two tall plants. When considering how I should heat this so as to keep out frost (for it would be idle for me to attempt anything more), various plans were suggested to me. Boilers of different kinds were proposed, but I felt that there would be a great expenditure of power with the smallest boiler I could get, much of which would be wasted. A brick flue I was aware was generally objectionable, as I knew how often the smoke escaped and how difficult it was to keep it clear; and so, at the suggestion of a clever jack-of-all-trades (but one who is good at all), I determined to try drain pipes. Those which I procured were what are ordinarily called 6 in. pipes in diameter, and glazed. About 8 ft. from the furnace was built as an ordinary flue, as the drain pipes could not bear the heat of the fire so close to them; these were then laid round the house

close to the wall, turned into the lower house, and thence into the chimney. This did its duty well, so far as keeping out the frost was concerned; but I experienced considerable inconvenience owing to the accumulation of soot in the pipes, and the consequent necessity of taking out the elbows several times during the winter, and, as this disarranged the level of the pipes, it became necessary to make some alteration so the man whom I had employed before suggested that instead of carrying the pipes all round, they should be brought somewhat more into the house, and that three places should be made of brick with a tile on the top, from which all parts of the piping could be reached. This would be made clearer by a small diagram, but in default thereof, I would say that the brick flue of about 8 ft. is built close to the outside wall of the house, the piping then takes a slant towards the inside instead of, as before, running parallel with the outside. The length to the first opening, which is in the centre of the house, is about 7 ft., then a straight piece across to the next opening of about 4 ft., then another slanting piece of about 7 ft. to the third opening, and then another piece of about 8 ft. to the end of the house. I am not quite sure of the exact measurement (being away from home) but it is near enough for all practical purposes. We have had now a pretty severe spell of frost, and I have found that, by banking up the fire between nine and ten o'clock, it keeps in all night, and frost is excluded. I would, therefore, from my own experience of some years, say to all who wish to heat a greenhouse of the size of my own or smaller, that the cheapest and easiest managed is such as I have described. It may be very unscientific, and may cause a smile on the faces of those who have Duplex, saddle, and all other kinds of boilers at their disposal; but, after all, the question is what answers one's means and objects.

The house itself is cheaply built. There are no movable sashes in the roof; the glass is simply laid on the rafters, while there is one small sash about 2 ft. square in the centre for ventilation. By this I mean that there are no sashes in the roof; however desirable they may be, they add very much to the expense, and as economy was my object, the rafters were glazed in the usual way with putty, for I was not rich enough to experimentise with some of the new methods of glazing, which seem to supply a want in horticulture. The sides are glazed in the same way, but there are three small sashes on each side for giving air, while over the door there is another, and also one at the further end. Thus there is abundant facility for giving air; and, as the house stands out in the full blaze of the sun, it becomes very necessary in the summer. I have adopted for shading some of Collinge's shading, nailing it on the inside of the house, and leaving it up all the summer. I find that it is not sufficiently thick to draw the plants at all, and yet sufficiently so to ward off the direct rays of the sun.

Such is my amateur's greenhouse. It was inexpensive in the first instance, and is equally so in keeping it up. In another paper I will detail the manner in which it is utilised; and I can only say that I very much doubt whether many persons with ranges of houses at their disposal have had more enjoyment out of them than I have had out of my humble effort.

DELTA.

PREPARING LILACS FOR FORCING.

Those of your readers who visited the Paris International Exhibition must have envied the success achieved in producing the pot Lilacs for early flowering, and yet their cultivation is of the easiest kind. The best varieties for the purpose are Charles X. and Dr. Lindley worked on the common Lilac, which may be procured abroad from the open ground for a few shillings per dozen. These should be planted out in a sunny border and closely cut back so as to induce fresh growth. In the autumn three or four of the strongest shoots should be again cut back to the first pair of buds and the remainder may be entirely removed, as six or eight flowering branches are sufficient for the first year of blooming. About the middle of the following August, or not later than the 21st, the plants should be lifted and as much as possible of the soil shaken from the roots, and, at the same time, all coarse root-growths should be removed. They should then be potted in good soil

in 6-in. or 7-in. pots and placed in a cool situation and well watered. They will receive no check by this treatment, and by the end of the year they will have made abundance of fresh roots, and probably every branch will terminate with two or more flowering buds, which may be known by their plumpness. If any doubts exist of their being such, it is advisable to cut one vertically through the middle with a sharp knife, when the flowers may be easily distinguished. If there is reason to believe that all, or nearly all, are leaf buds cut the shoots closely in, and plant out again, so as to induce a stronger growth for the following year. If in June or July any grow too vigorously they should be checked, either by partly cutting the roots, or by lifting the plants up bodily with a fork and then replacing them in the hole without pressing the soil too closely round them, so that by the check the shoots, when fully matured should not exceed 12 in. or 18 in. in length. Thus prepared they will be ready for forcing early in the year. After flowering cut them back to the old wood, and place them in a cool frame till April, when they may be planted out, and the same treatment followed as directed in the first instance. As the plants can only be successfully flowered every alternate year they should be cultivated in two batches, so as to have one in bloom each year, and by ordinary attention they may be kept in a flowering state over a long series of years. Periodically the root must have a thorough cutting in, so as to be able to pot in reasonable-sized pots. This is best performed in August after the first cutting in after flowering. If it be desired to have white flowers they may be obtained by forcing with a temperature of 60° to 70° in a perfectly dark room or closet, slightly ventilated so as to prevent moulding. So soon as the heads of flowers are fully developed, and the flowers begin to open, the plants should be gradually exposed to the light previous to planting in the conservatory.

T. B.

BOTTOM HEAT.

THE most noticeable feature of Mr. Baines' reply to my remarks on this subject (p. 127) is the complete abandonment of the plea set up by him that in growing plants without bottom heat he was acting in conformity with Nature. I am myself ready to acknowledge his success as a plant cultivator, and at the same time prepared to prove, from his own statements, that he never grew his plants successfully without furnishing them with a root temperature "in a volume equal to that in which the heads of the plants are placed," though he has now told us that such a practice is "diametrically opposed" to Nature. Let me just state here, however, that the question under discussion does not relate to the mode of applying bottom or root heat. On that head people differ, but simply to the propriety of furnishing it in some form or other. To prove what I say your readers have only to refer to the numerous articles Mr. Baines has written on plant culture, but I will content myself with quoting from what he has written in *THE GARDEN*, more especially because his articles relate to some of the very subjects, which he now tells us he grew without bottom heat. In *THE GARDEN*, last April, he recommends a temperature of 70° or thereabouts as a night temperature for stove plants, and a proportionate rise by day; and last August, writing on the culture of *Ixoras*, which he grew in his stoves along with other plants, he tells us that the temperature of the house from the beginning of May throughout the summer might range from 70° to 76° minimum to 95° maximum, or a few degrees higher, with shutting up, &c.—shortly, we may say from 70° to 100°, which is about the ordinary heat of stoves in summer. Now, the mean of these figures is 85°, and this is the temperature at which Mr. Baines kept the roots of his stove plants, for I do not suppose he or any one else will dispute the fact that the mean temperature of the soil in the pots of plants cultivated under glass is just equal to the mean temperature of the air of the house; no body can be either hotter or colder than that which heats it. Notwithstanding these facts, however plainly deducible from all that Mr. Baines has written, he tells us, in his article on bottom heat, that when the heat of his stove had risen above 80° he lifted the plants out to keep them cooler. The said bed, it is further stated, was heated by pipes or fermenting materials. How, therefore, he kept the temperature of the bed lower than the air by which it was surrounded under these circumstances is a puzzle which he alone can explain. And, says Mr. Baines, referring to the results of the practice above described, "I have on this system cultivated individual plants for twenty years, and have had them as strong and vigorous then as during the earlier portion of their existence." What better testimony could any one

want in support of that practice which Mr. Baines now condemns. In conclusion, I would only state that my own practice in no way differs from that of Mr. Baines', only he describes his practice wrongly. I never plunged our hot-house plants of any kind in a bed heated by pipes or fermenting materials, but have always placed the plants on the bed or the shelves, as the most practicable method of conforming to the conditions under which they exist naturally as regards root temperature. I have plunged little else besides Pines and pot-Vines, and in their case it was done more to provide an equable degree of moisture at the root than anything else, for I was always careful to see that their bottom heat did not exceed the mean of the top-heat, which they would have received all the same had the pots been set on the surface of the bed, and I have stated as much as this before in some of the earlier numbers of *THE GARDEN*. I would just add, also, that it is clear that Mr. Baines, in his lengthy article in a contemporary, attributes evils to bottom-heat that are really caused by plunging the plants in the bed more than anything else. I allude to his complaints about the plants drooping and fading when taken to exhibition or elsewhere. The very same happens to plants growing vigorously that are plunged in a cool bottom out-doors, when they are lifted out of the plunging material, as any one knows who has had much to do with plants. That great gardener, Knight, because he did not use the bark bed to plunge his plants in was cited as one who did not believe in bottom heat, but he "disavowed entertaining any such sentiments," pointing out, as I have done in Mr. Baines' case, that, although he did not plunge his plants, their roots were not subjected to a lower temperature than that to which their tops were exposed. How Mr. Baines has overlooked a fact so palpable in his declamations against bottom heat during the past few years I cannot understand.

Wortley.

J. SIMPSON.

[Here this discussion, we think, should cease.]

WINTER CONSERVATORY PLANTS.

MR. FISH (p. 128) says he is surprised to find *Hedychium* and *Monstera deliciosa* included amongst plants suitable for conservatory decoration in winter, and adds that even the hardier *Ficus elastica* would soon look "seedy" if subjected to ordinary conservatory temperature; but allows me to state that I had no thought of summer decoration when I prepared my list from plants actually growing in decoration under the conditions described, and where the temperature was below the minimum of 45° for weeks together; the *Hedychium*, too, had been used on several occasions for hall-room decoration, necessitating their exposure in very severe weather. Treatment of that kind would have killed such plants if they had been kept in a stove temperature, a circumstance that induced me to bring them under the notice of your readers. I know that they keep growing more in winter in a stove temperature, but I feel pretty sure that they may be kept in perfect health without it. I may mention that we have a fine plant of *Monstera deliciosa* growing and fruiting on the back wall of a Vinery that has had only fire heat enough to keep out frost, yet it looks as healthy as need be. The *Hedychium* with their tall, Canna-like leaves and stems, and the *Monstera* with its large and handsome foliage, are plants distinct in character, and anyone trying them as permanent occupants of the conservatory will have no reason to regret it. Does not Mr. Fish remember the fine plants of *Hedychium* *Gardnerianum* that used to grow and flower so well in the large conservatory at Chiswick in years gone by? It is by growing such plants in high temperatures and then removing them to a lower one that renders them unable to withstand cold. Fruiting plants like the *Monstera* and growing them for the decorative properties of their foliage alone are two very different things; for fruiting it should have a Pine stove temperature. Another subject is suggested by Mr. Fish's communication, viz., the inadequate heating power so often used in conservatories. It is well known that there is nothing more wasteful than boilers and pipes too small for what is required of them. Small boilers are bad enough, but small pipes are worse, for where the water has a long distance to circulate, though hot enough when it leaves the boiler it gets quite cold before it reaches the extreme divisions. Such a winter as the past is useful occasionally, if only to settle the merits of what are called heating apparatuses, as many of them cannot bear so severe a strain as that to which they have lately been subjected.

J. GROOM.

Linton.

Diplacus or Shrubby Mimulus.—I find plants belonging to this section of the *Mimulus* family most useful for many purposes. They last long in bloom and are easily grown; they do well in a heated pit or cold greenhouse, in any place, in short, out of the way of frost. Give them water enough in winter to keep them from getting dust dry; in spring prune them and pot and grow them on,

and during summer they will make good plants either for the conservatory or for house decoration. Cuttings struck in spring and grown on rapidly also make useful plants, and bloom well through the autumn months. One or two good kinds are Golden Pheasant, Gordon's Stella, and a sort known by the name of antarcticus. All these bloom well if planted out in spring in the open borders and taken up for winter decoration.—J. C. F.

PROPAGATING.

ANTIRRHINUMS.—These are best propagated in September; take well-drained 4-in. pots and fill them with rather sandy soil; select the cuttings from young side shoots, and make them as shown in fig. 1; insert them firmly with a small peg

Fig. 1.—Cutting of Antirrhinum.

and give them a good watering with a fine-rosed pot; place them in a cold frame out-of-doors and cover them up, sprinkling them over very slightly every morning, and leaving them open for an hour to dry the leaves if the weather be favourable. In about three weeks they will emit roots, when they may be gradually hardened off, and either potted into store pots or kept

Fig. 2.

Fig. 3.

Cuttings of Antirrhinum.

in the cutting pots on a shelf in a cool greenhouse during the winter; keep them rather dry and pot them off in February. In order to increase scarce and new sorts cuttings may be made in spring, using either single or double eyes, as shown in figs. 2 and 3; fig. 3, split down the centre, may be made into two like fig. 2; they must be placed on a gentle bottom heat in the propagating box, and will be ready to take out in ten days to gradually harden off. H. H.

Sizes of Propagating Pots.—Opinions differ as to the sizes of pots best suited for striking cuttings in; some think 3-in. ones best, others 6-in. ones. My own opinion is that size is of little consequence; some do best potted singly at first, and then the roots do not get broken in potting, as they can be transferred from one pot to another without injury in any way, a point of great importance in the case of brittle-rooted plants. My intention now, however, is to point out to the inexperienced the way in which 8-in. pots may be used to the best advantage; I prefer them, in fact, to either 6-in. or 7-in. pots. In the case of 8-in. pots, instead of putting crooks in them in the usual way, take a small thumb or other pot, according to depth (as they differ in that respect from most potteries), and invert this upside down in the large one; then fill all round it to just above its top with small crooks; on this put some rough material to

keep the drainage open, and then fill up with soil in the usual manner. In this way I have found cuttings to strike as quickly and as well in the centre as round the sides of the pot; the inverted pot forms, as it were, a chamber by means of which the bottom heat is equally distributed all over the pot, and the soil does not remain wet so long in the middle as it otherwise does, causing the cuttings to damp off, especially such as *Verbenas* and those of a similar character. I have found pots crooked in the way just recorded useful for starting such plants as *Alternantheras*, *Coleuses*, &c. I put the pots in evaporating troughs and keep them filled with water; here cuttings of such plants strike in a very short time. Now, when the demand for summer bedding plants is great, one has to make all sorts of shifts where there is no proper propagating house.—J. C. F.

PLANT CULTURE FOR MARKET.

Indoor Flowers.

CALCEOLARIAS, both of the shrubby and herbaceous kinds, are grown for market; but the former are offered in the greatest quantity. An improved variety of *C. aurea* is most sought after. It bears large trusses of bright yellow flowers, and is dwarf and compact in habit. Cuttings of it are struck in cold frames late in autumn; their shoots are pinched back early in the year, and they are potted into 5-in. pots and kept in a half shady cool house or pit close to the glass, when they throw out abundance of flowering shoots. The soil used is loam, leaf-mould, and road sand.

MUSK does not pay for growing to any great extent, except for early work, but florists grow it to fill in between larger plants sent to market. Pieces of the roots are taken up, placed in 5-in. pots, and put in heat soon after the turn of the year, or earlier, when good flowering plants in spring are the result. The Giant Musk sent out by Messrs. Harrison & Sons, of Leicester, makes a good market plant; both its flowers and leaves are large, and its scent is as good as that of the common variety, and it grows equally well in window-sills or rooms.

LILACS are forced for the sake of their blooms in winter. The earliest supply comes chiefly from France, where the plants are grown in the dark, in order to make their flowers become white. The plants to be forced are lifted from the open ground, potted and placed in heat, keeping them well syringed overhead. When the blooms begin to open, mats are placed on the roof of the house or pit and round the plants in order to shut out light, and in this way almost pure white trusses of flowers are produced. After flowering, the plants are again turned out of doors. Forcing in strong heat has also the effect of making the flowers white.

LOBELIAS are grown in large quantities in pots. They are chiefly struck from cuttings put in in the autumn. When rooted, they are potted into 6-in. pots, placed close to the glass, and receive plenty of air and water. Thus treated, they become compact, floriferous plants in May and June.

STOCKS are grown by thousands for planting out in beds during the summer. The seed of the Intermediate variety is sown late in autumn in cold frames, and when up the largest plants are selected for pot culture; the others are allowed to remain till they are fit for sale in spring. Some plant Stocks out-of-doors, and lift them into pots when in bloom.

ASTERS are sown in spring in heat, and planted out in good rich land. When in bloom they are potted early in the morning, whilst the dew is on them, and sold when fresh and bright; before the day is over, however, if a hot one, they look just the reverse, the shift rendering them unable to withstand strong sunshine.

BEGONIAS of the *Weltoniensis* and *Saundersi* types are grown largely for market; also an unnamed seedling kind with pure white blossoms, which are produced in abundance from amidst a mass of dwarf, stocky foliage. The *Saundersi* variety is very floriferous, large trusses of scarlet and pink blossoms hanging in profusion from every shoot. Begonias are well adapted for decorative purposes, as they are easily grown and last in flower for a considerable time.

To the above may be added *Veronicas*, *Epiphyllums*, *Ixias*, *Sparaxis*, *Petunias*, and *Clematis*, all of which are sent in quantity to market, both in the form of plants and cut flowers. The Mock Orange, too, is grown by a few florists planted out in fruit houses, where it yields abundance of blossoms early in spring, which are much prized for bouquets.

THE LAURUSTINUS is grown largely by some growers for forcing into bloom at Christmas. At that season, owing to the dullness of the weather and the forcing, its blossoms come much whiter than those produced at their natural season out-of-doors. Plants for forcing are generally obtained from the Continent or from nurseries in which they are largely grown for supplying the trade. They are potted in October and November, and introduced into a warm temperature under which, with plenty of water at the roots and frequent syringings overhead, they soon open their bloom. After flowering, the plants are either plunged in beds of ashes or soil out-of-doors, or are turned out of their pots into good soil until the following autumn, when they are forced as before. A few growers, however, raise their own plants, and dispose of a quantity of them when in a small state for window decoration, &c. In this case cuttings are taken off in August and September, when the wood is becoming firm, and are inserted thickly in pits or frames, into which have been introduced a few inches in depth of sandy soil, made firm. They are kept close for a few weeks, after which air is freely admitted. By the spring they will have made good roots, and they are then transplanted into prepared beds of rich sandy soil in the open air. Here they remain for about two years, when they are lifted and potted, allowing a little room for the roots to expand. After this the pots are plunged in a sunny position, and shifted on into larger pots as may be required. Some have their stems kept clear of shoots, so as to form standards; others are allowed to grow naturally into sturdy bushes. When they have become well-established plants in 6-in., 8-in., or 9-in. pots, well set with buds, they are moved into the houses in November and December, to open their flowers. By inserting a quantity of cuttings every year, a succession of good plants is thus kept up.

The foregoing list might be considerably lengthened, but the subjects mentioned form the leading market indoor flowering plants grown in and about London.

Outdoor Flowers.

Market gardeners who grow fruit and vegetable crops find it remunerative to grow hardy flowering plants between them and in positions, such as under the shade of trees, where other crops would not succeed satisfactorily, some of these flowering plants do well. The most important under-crop of this kind is that of Moss Roses, to which reference has already been made, but the following are also profitable and much grown:

WALLFLOWERS.—In favourable seasons early planted Wallflowers afford abundance of cut bloom throughout the winter, and in February and March good prices are obtained for it; even in April Wallflowers realise fair

prices; but after that they become very cheap indeed, good large bunches of them being often sold for 1d. and 1½d. each. The advantages of early sowing and planting, so that blooms may be procured in fair abundance through the winter, and in large quantities in early spring, are, therefore, at once apparent. From March to April, and even earlier in mild seasons, Wallflowers are brought to market in waggon loads. The blooms are cut with stalks from 6 in. to 9 in. long, and are tied in bundles, as large as can be grasped with both hands, with small withes or bast. They are usually grown between fruit trees or in other shady places, where they thrive remarkably well. In the neighbourhood of Isleworth, Twickenham, and Feltham, hundreds of rows of them nearly half a mile in length may be seen. The seed is sown broadcast in beds in the open air in February, and when the plants are large enough to handle they are transplanted into rows from 12 in. to 15 in. apart. During summer, if the place which they occupy be very much shaded, they often become a little "drawn," but as the leaves fall off the trees in autumn they begin to branch out and grow rapidly, and by December many of them are in bloom. After all the flowers have been cut, the plants are dug up and thrown away, and are replaced by young seedlings, which are by that time ready for transplanting. Before planting, however, the ground is always liberally manured and deeply dug. Market gardeners never keep Wallflowers more than one year, young plants being always found to produce the most and best bloom. Seeds are saved from plants possessing the best branching habit, and which bear the darkest-coloured blossoms; when in flower the plantations of them are gone over, and plants possessing these qualities are marked by placing a stake by the side of each. These are allowed to remain undisturbed until the seed is ripe, when they are pulled up, roots and all, and housed in a dry place until a convenient season arrives for threshing out the seed. The old-fashioned market garden Wallflower is the kind still sought after; it is found to bloom better and earlier, and the flowers, which are dark and rich in colour, realise more money in the market than those of any other kind. When plentiful, Wallflowers are not taken into the flower market, but are disposed of from the waggons outside the building to hawkers. C. W. S.

The Pampas Grass in avenues would doubtless, as A. D. suggests (p. 118), have a grand effect if properly treated, and it might also be planted by the sides of carriage drives, if of any length where a good bold curve could be secured. Supposing the drive to be about half a mile in length, I would plant it as follows. Commencing at 25 ft. from the drive, I would plant alternately at 30 ft. apart *Deodars* and *Aracaria imbricata*, and midway between each of these, and 10 ft. nearer the drive, a plant of *Pampas Grass*. At 30 ft. from the *Pampas Grass* and exactly behind it, I would use alternately *Wellingtonias* and *Cupressus Lawsoniana*. If space could be allowed for a third row of *Conifers*, I would select *Cedar of Lebanon*, *Picea nobilis*, *P. grandis*, *P. Nordmanniana*, *Abies Douglasi*, and *A. Smithiana*; and at 40 ft. from the *Conifers* I would have a double row of deciduous trees to form a shady walk. They should be 15 ft. apart each way, and might consist of *Limes* and *Chestnuts*. The *Aracaria* and *Deodar* like a deep sandy loam, or peat; therefore if planted in wet heavy ground, it should be well drained, and the trees should be planted on slightly raised mounds in suitable soil. The *Aracaria* soon loses its lower branches if planted in wet heavy land, but when seen as at Bearwood it is a grand object. The style of planting here indicated is more suitable for curved than for straight drives, and the greater the length the grander the effect would be. *Elms* or *Chestnuts* doubtless are the most suitable for straight drives; yet I have often thought that the Oak might be used for avenues, as it is much more durable than either of the former, and is in every respect a grand tree.—W. L., Reading.

PLATE CLXVII.

THE TIGRIDIAS.

(WITH A COLOURED PLATE OF *TIGRIDIA PAVONIA GRANDIFLORA*.)

Drawn by Miss PIERREPOINT.

To the numerous, and, for the most part, showy family of Iridaceous plants belong many garden favourites, but amongst them few can rival the Tigridias, especially the variety represented in our plate; indeed the magnificent colour, added to the singular conformation of the blossoms, can scarcely be surpassed by any plant in cultivation. Yet, singular as it may appear, Tigridias of recent years have held but an inferior position amongst outdoor garden plants; whereas, fifty years ago they formed, with other half hardy bulbous plants, one of the more important features in most gardens. Happily the taste for them is evidently reviving, and we shall have gained our purpose if the present illustrations and accompanying remarks tend in any way to increase their popularity, and place them once again amongst the finest outdoor plants cultivated by the many. According to the latest revision of the Order by Mr. Baker the genus consists of about six species, comprising *T. Pavonia*, with its numerous forms, and the Shell Tiger Flower (*T. conchiflora*), which is classed as a native variety of *T. Pavonia*. The remainder include those formerly known as *Beatonias*, but, as their flowers are very fugitive and somewhat small and dull in colour, they cannot be considered generally speaking of much horticultural interest. These are *T. atrata*, with greenish flowers, pencilled with dark-coloured spots like a Fritillary, *T. curvata* and *violacea* with purplish blossoms. *T. lutea* and *T. Van Houttei*; the former with yellowish flowers $1\frac{1}{2}$ in. across, spotted with purple, is figured in a late number of the "Botanical Magazine"; the latter is the latest addition to the genus. It grows about 1 ft. high, and has purplish flowers $1\frac{1}{2}$ in. across. It was raised from seeds received from Mount Islapalapa, in Mexico, at M. Van Houtte's establishment at Ghent, and was, moreover, the subject of a coloured illustration in the "Flore de Serres" for 1875. Geographically considered, we find all the species natives of Mexico, with the exception of *T. lutea* which inhabits Chili and Peru. Other kinds of Tigridia are enumerated in trade lists, but most of them belong to totally distinct genera. For instance, *T. undulata* is a Ferrara, plants essentially natives of the Cape. *T. celestis* is *Phalocalis plumbea*, a native of Brazil. *T. Herberti* is synonymous with *Cypella Herberti*, also of Brazilian origin; whilst *T. canariensis* is evidently a misnomer, as none are found in the Old World. It is probably a fine form of *T. conchiflora*.

The Tiger Flower (*T. Pavonia*) is a very old inhabitant of gardens, having been first introduced to them nearly a century ago, and, on account of its possessing a sporting tendency, many seminal varieties have sprung from it, the most noteworthy being *T. Wheeleri*, a kind which has larger flowers, and a shade deeper in colour than those of the type. *T. splendens* and *T. speciosa* are also larger, and their colour is brighter; but description fails to convey an idea of the distinctive points of these varieties. The form *grandiflora*, which we figure, is superior to the type on account of its larger and richer-coloured blossoms, its small, fiddle-shaped petals being more copiously spotted, and the deep green of the plaited, sword-like foliage much enhances the effect, as will be seen by the annexed woodcut. It is apparently a native form, and has been grown and flowered with great success by Messrs. Barr & Sugden, from whose grounds the flowers represented in the annexed plate were obtained.

The Shell Tiger Flower (*T. Pavonia* var. *conchiflora*) differs from the type in being of less robust habit and in the blossoms being bright yellow and spotted with scarlet. That this is but a variety of *Pavonia* is evident from the fact that there are recorded instances of bulbs producing blossoms in which yellow predominated in the early part of the season, and later on the same bulbs bore scarlet flowers.

The two kinds will also intercross freely, the result being hybrids partaking more or less of the character of both sorts, such as *T. aurantiaca*, *Pavonia-conchiflora*, *intermedia*, all of Continental origin, and *Watkinsoni*, produced some years ago by Mr. Horsefield, of Manchester, with flowers like those of

conchiflora, and a habit very like that of *T. Pavonia*. The only detracting point connected with these charming flowers is that they display their beauty but for a day only; this is, however, compensated for by each stem bearing a continuous succession of blossoms during the flowering season, so that it is advisable to plant in groups, in order to obtain a continual show of flowers.

As regards culture, about the end of March prepare a bed for them, and if in a partially shaded position so much the better; thoroughly drain it with rubble, &c., placed at a depth of $1\frac{1}{2}$ ft. or 2 ft., and fill in with a compost of rich loam and well-decayed leaf-mould in equal quantities, with a good sprinkling of sand, all being well mixed up together. In the first or second week in April plant the bulbs from 5 in. to 6 in. apart, and 3 in. deep, placing a little sand under and around each. They will require no further care, except, if the weather be dry, giving them slight waterings up to the time when they begin to expand their blossoms. When the foliage becomes decayed in autumn, the bulbs should be carefully lifted and tied in bunches of about twelve, according to their size, and

*Tigridia Pavonia grandiflora.*

hung in a cool, airy place until next planting season. Some cultivators allow the bulbs to remain undisturbed during the winter, and in warm localities and in light soils, perhaps, it is advisable for a year or two; but, as a general rule, the plan recommended is preferable, as it entails but little trouble, and the bulbs are at hand for the purposes of propagation. The latter is effected by means of offsets, which are freely produced, and if carefully removed and treated as above, they will flower the second year. Seeds afford a wholesale means of propagation. They should either be sown as soon as ripe or in the following spring in shallow pans, and placed in a heated frame or greenhouse. As soon as the seedlings are of sufficient size they should be pricked off into other pans, after which they should be treated as matured bulbs, and in the third and fourth season they will produce blossoms.

W.

Storks in Gardens.—At Ferrières, for the last four years a pair of storks, male and female, have been in the kitchen garden, and also another pair in an enclosed nursery where Conifers, Roses, Strawberries, and such like are grown. These birds have been found most

useful, destroying such pests as adders, slugs, worms, mice, moles, snails, spiders, flies, &c. They walk about in the garden from morning till night doing their work, and they spoil nothing, touching nothing whatever, either fruit, vegetable, or flower.

TREES, SHRUBS, & WOODLANDS.

USEFUL CONIFERS.

I QUITE agree with all that Mr. Baines (p. 106) has said in favour of *Pinus Laricio*, and would strongly recommend its being extensively planted in woods and plantations with a view to profit, for, unquestionably, it is one of the most valuable of all the Conifers, and succeeds well where many others would fail. Near the sea coast, for instance, it grows with a vigour equalled by few, but in such situations there should be plenty of other things planted with it to assist in breaking the force of the winds, and, when thinning is done, it should be gradual, as those left get cut about through sudden exposure, and sometimes completely uprooted. It seems a pity that so much ground should be occupied about the country in the growth of so many trees that are quite worthless for their timber, and more particularly so as we are dependent, in a great measure, for all we use on the supplies we get from abroad, but, somehow or other, Spruce appears to have been the favourite with our foresters, but why this should have been so I am at a loss to conceive, as it has no special merit beyond its symmetrical shape in an ornamental point of view, and in other respects it is quite worthless, unless it be for using as fuel. There is another Conifer to which I would call attention, which is *Abies Douglasi*, the wood being close grained, hard, and tough, and so full of resinous matter that the weight of it greatly exceeds that of the Larch. As to growth, planted on the same soil, it seems a race between the two which shall obtain the greatest altitude in the shortest space of time, but, conditions being about the same, there is not much difference in the rate of progress, either in an upward direction or in the girth of the stem. Up to the present their price has been against a more extensive use of them for planting, but, as Mr. Baines points out, this ought not to be so much a consideration, as with this and the *Pinus Laricio* it is an easy matter, when forming fresh plantations, to place these at wide distances to allow space for their full development, and then fill in between with Larch, Scotch Fir, and other commoner things, to act as nurses and draw the others up, and thus prevent the spread of side branches, which, if allowed to have full play, rob the leader and spoil the quality of the timber by causing large knots in the planks. The Douglas is a Fir that likes plenty of shelter, and therefore comes in admirably for filling in blank spots in woods where there is sufficient light and room upwards, and when they can be so favoured, it is surprising the headway they make. In open positions the inclination of *Abies Douglasi* appears to be to spread and make the most growth in a horizontal direction, but, checked by being surrounded by others, it rushes up at the rate of 3 ft. in a season. Where a few choice and distinct-looking Conifers are required for ornament to plant in conspicuous places, the following will be found about the most desirable:—*Picea grandis*, *P. nobilis*, *P. Nordmanniana*, *P. magnifica*, and *P. cephalonica*, the latter of which should be so situated as to be not only sheltered by other trees, but where the sun does not strike it early in the morning, otherwise it is apt to get its soft buds injured by spring frosts on account of the early growth it makes. Among *Pinuses*, besides the one already named, *P. austriaca* is deserving a place in any grounds of sufficient extent to accommodate this class of plants, as is also *P. Lambertiana*, the rich deep green of which is quite pleasant to look upon, and shows up in fine contrast against several of the foregoing that have more of a silvery hue.

S. D.

***Paulownia imperialis*.**—I send you herewith a sprig of flower-buds out the other day from the head of a *Paulownia* about twenty years old, growing here in a sheltered garden a mile from the shores of Mount's Bay, in Cornwall. The tree in question flowered, but feebly, in May, 1878, and once before. The specimen which I send is one of several sprigs, and is one of the smallest. I was surprised to find the buds apparently uninjured by the long and severe win-

ter from which we have just emerged. Does the *Paulownia* usually form its flower-buds at the close of the season, and does it often flower in England?—J. J. ROGERS, Penrose.

"TREES OF THE FUTURE."

I CAN endorse all that Mr. Woodall says (p. 71) respecting the merits of the Cedar of Lebanon, and still more so of the Mount Atlas Cedar, and of the great mistake that is made in planting the Decadur in preference to the Mount Atlas Cedar, especially when introduced as the Decadur is, by hundreds, into places suitable or unsuitable without any apparent reflection or consideration. With equal justice the same may be said in regard to the large amount of Coniferous and Taxaceous trees that have been brought into the country within the last forty years, and concerning which, despite their handsome appearance and the free growth which many have so far made, there is yet a good deal of uncertainty as to how they may behave in this climate. There are few who will attempt to gainsay the desirability for as much variety as possible in the trees employed for decorative planting in parks, or in what are usually designated dressed grounds in the more immediate vicinity of dwellings, be such grounds more or less in extent, but there can be little question that in situations like these the choice is frequently in favour of uncertain novelties rather than of trees that are not only well proved as to their hardiness, but also as to their superiority for effect in the positions to be occupied. This is not simply a mistake in the ordinary acceptance of the term, but one that is fraught with consequences that will take longer to correct than those who fall into it are likely to see fully rectified. But, at all events, there can be little doubt that amongst the introductions that have appeared within the last half century from California, Chili, and later from Japan, some will be found in every way deserving of being classed as trees of the future in such positions as I have named, and probably for grouping in considerable quantities in woods, where masses of dark evergreen foliage, as well as diversity of form, are alike desirable, independent of what may turn out to be their value as timber trees. But in speaking of what are to be the trees of the future, the subject embraces a much wider field than woods and pleasure grounds combined, when we look at the whole surface of the land collectively and notice what is being done, or rather left almost wholly undone, in the shape of planting trees to take the place of those existing. I am aware that from a purely cultural point of view trees in hedgerows, as well as singly, or in groups in cultivated ground, are looked upon with disfavour; but imagine them all removed and I think even those who entertain the most utilitarian ideas on the matter would hesitate before the broad landscape of the entire country was made treeless in all except such as are comprised in woods alone; yet with a few exceptional properties, this is the direction in which matters are gradually approaching, for direct our course where we may through almost any country in the kingdom, we may go scores of miles without seeing a single tree planted (except as I have already stated in the immediate vicinity of dwellings, or in the few places where new plantations of some extent are being made) to take the place of the trees that now dot the landscape, and of which it may with truth be said nineteen twentieths are at present past their best, and surely, if slowly, on the wane. Where there is one extensive landowner who is mindful of this, and who makes corresponding provision for the distant future, there are a score who never give it a thought, or allow thinking to suffice. This may no doubt be attributed to the fact that tree growth is slow, extending over the time allotted to not one but a good many generations. In musing over the subject the thought often occurs, what at some distant time will be the appearance of the country? Will no general movement ever be made until the trees that now deck the landscape are so far gone as to necessitate resort being made to the quick-growing Poplars, so painfully monotonous in some parts of the Continent? Or are the trees of the future, looking at the subject from this point of view, to be found amongst the many comparatively new comers? I think not. Nor is it desirable that they should be, for, like Cobbett's whilom favourite *Acacia*, it is more than likely they would turn out lamentable failures as regards supplying the places of the Oak, Ash, and Elm, which combine excellence in the timber which they produce with general effect not likely to be surpassed or even equalled. Not that it is advisable to exclusively confine the general planting to the above-named; *Sycamore*, *Poplar*, *Chestnut*, *Lime*, and *Beech*, with, for variety, a limited number of others, amongst which ought to be a few evergreen species, should no doubt be added. Much is from time to time said about what are to be the trees of the future. I think, upon a little reflection, it will be seen that such trees as have been in the past should be those of the future, with the addition of the kinds that have been hitherto planted too sparingly.

T. BAINES.

NOTES FROM KEW.

Greenhouse Plants.—Several noteworthy Australian plants are now in flower in the conservatory. Amongst these is the *Fuchsia-like* *Genethyllis*, a Myrtaceous shrub discovered by Drummond many years ago in the Swan River Settlement. It forms a neat, erect, much-branched bush about 2 ft. high, and on the end of almost every branch is a drooping flower-head, consisting of about six blossoms, enclosed by a row of deep red bracts about 1 in. long. The foliage is small, and has a very agreeable aromatic fragrance similar to that of some of the *Diosmas*. Another charming shrub is *Boronia tetrandra*, which inhabits South-east Australia and Tasmania. It has a remarkably neat habit, and grows about 2 ft. in height, with much-divided foliage consisting of about three pairs of very narrow leaflets. It produces its pretty bluish-coloured blossoms in abundance and continues in perfection for a long time. *Stenanthra pinifolia*, a plant belonging to the *Euphrasia* family, is also from the same region and an old introduction. It much resembles a *Pinus* in miniature, having clusters of small, needle-like leaves and narrow, tubular blossoms 1 in. long, deep rose-coloured tipped with green. Of the numerous kinds of *Grevillea* none are more deserving of more extended culture than *G. thelemanniana* (syn. *G. Preii*), as it forms one of the most elegant plants imaginable, having delicate pinnate foliage resembling that of the common Southernwood, and numerous terminal pendent clusters of beautiful rich red and yellow flowers of very peculiar structure. It comes from the neighbourhood of Perth in South-west Australia, where it forms handsome spreading bushes from 3 ft. to 5 ft. in height. It is to be regretted that these fine plants from the Southern Hemisphere are not more generally cultivated than they are, as no class of subjects is more serviceable for enlivening our greenhouses during the dull season of the year. Perhaps they may be thought difficult to manage, but if plenty of light and air be afforded them, with due regard to liberal drainage, careful watering, and a good peaty compost as essentials, the difficulty, if any, may be surmounted. *Arctostaphylos tomentosa* is a handsome Californian Bearberry growing about 3 ft. high, with oval, pointed leaves and terminal, dense clusters of waxy-white blossoms. Though treated as a greenhouse shrub it is quite hardy.

Orchids.—*Angreum eburneum* is a stately epiphyte with large, leathery, sword-like leaves spreading in a fan-like manner, from the axils of which are produced stout, erect spikes, 2 ft. or more in length, bearing two rows of blossoms with a large tip of ivory whiteness, the other divisions, and also the spur, being pale green. The variety *superbum* has flowers larger than those of the type, and in *A. virens* they are suffused with green, and all are very sweet scented. They are natives of the Islands of Madagascar and Bourbon. One of the best and most useful of the yellow-flowered *Dendrobies* is *D. fimbriatum* *oculatum*. Its blossoms are borne in graceful, pendulous, loose racemes and are 1½ in. across, of a rich apricot yellow; the lip, which is roundish, is delicately fringed, and has a deep brown blotch in the centre. This section of *Dendrobies* is accompanied by more foliage at the flowering period than occurs with the generality of other kinds, thus much enhancing the effect produced by them. We are indebted to the late Dr. Wallich for its first introduction to our stoves, he having sent it from Burmah many years ago; it also occurs in Nepal, but the coloraceous type is more prevalent at the last-mentioned place. The old *Phajus grandifolius* is probably too well known to need description; still it deserves a passing word. Its ample foliage is handsome, and sets off to advantage the stately spikes of large flowers which last a long time in perfection. *Brassavola cordata* and *venosa* are neat little epiphytes, much resembling each other; the former has a pure white heart-shaped lip, the latter larger blossoms with the lip white and spotted with purple at the base; both are natives of Brazil. Mention was made in the last notes of the African *Ansellia*, and a fine variety of it; another is now in flower bearing the name of *A. gigantea*, though on what ground it merits the name it is difficult to perceive, as it is smaller in growth than *A. africana*, and the flowers are also not so large, but they are very distinct in colour which is a pale sea-green sparsely spotted with brown, and the lip is a rich canary-yellow. The heart-lipped *Odontoglossum* (*O. cordatum*) though not so showy as some of its congeners is, nevertheless, very handsome, its flowers being 2 in. across, white barred with reddish-brown.

Stove Plants.—Foremost in interest and rarity is *Ptychosperma rupicola*, a handsome Palm now in flower in the Palm house. It is about 10 ft. high, with a noble head of elegant spreading foliage, and from the upper half of the naked stem is produced a much-branched inflorescence 1 ft. across, the whole of a deep blood-red colour, with numerous white star-like blossoms thickly studded on the twigs, rendering it very effective. Another Palm of great beauty is the Mexican *Chamodorea Sartori*, of which there are two or three plants, both large and small, flowering freely in the Aroid house. Unlike

the last, the drooping feathery clusters of small blossoms of a deep orange colour are borne amongst the deep green foliage, thereby much enhancing their beauty. In a small state this is one of the best of Palms for decorative purposes, more especially as it produces flowers annually. W.

NOTES OF THE WEEK.

Out-door Camellias.—Mr. Groom informs us that Camellias growing at Linton Park, Maidstone, in an exposed situation, have passed so far through the winter unprotected without apparently sustaining the least injury. The flower buds remain plump and sound, and promise to open freely. The climate of Kent may be considered a very favourable one, but it is nevertheless evident, that the Camellia might be planted out-of-doors in many places much more extensively than it is. It is even harder than the *Lamstrutins*, and therefore wherever that will succeed so likewise will the Camellia; i.e., provided the soil be such as it requires. Good loam, road sand, well decayed cow manure or leaf mould suit it admirably; a mulching of half-rotted leaves or manure during hot weather will also greatly benefit it.

Xiphion planifolium in flower at Bitton.—There is no doubt that this winter will have been most disastrous in the garden, but I am sure it will also be a winter of surprises. My first great surprise is that I have now in flower the beautiful *Xiphion planifolium* (Bot. Mag., 6352), though it has been in full leaf all through the frost and entirely unprotected. This has always been considered to be one of the tenderest of the family, so that it is said in the Bot. Mag., that "it can only be satisfactorily grown under cover." Yet it is wholly uninjured. I think the entire absence of sun may have had something to do with this, as it is very probable that a bright sun upon the fleshy leaves after or during the frost would have been fatal to them. The plant is better known as *Iris alata*.—HENRY N. ELLACOMBE, Bitton Vicarage, Gloucester.

Begonia glaucoflora for baskets.—This is one of the best of plants for furnishing hanging baskets for the conservatory during autumn, winter, and spring. It flowers freely, and plants of it can be grown into a good size in a very short time; cut sprays of it were shown at South Kensington the other day by Mr. Parr, who grows it extensively in baskets for the decoration of the conservatory at Harrow Weald Park, where it contrasts strikingly with *Polisettias*, and similar plants of an attractive kind.

Wall Shrubs and the Frost.—We noticed on walls in the Pine-apple Nursery the other day, several plants which are not generally thought to be perfectly hardy, much less to withstand the severe test to which they have been subjected this winter. On a low wall in a north-western aspect, *Abelia floribunda* is not in the least injured, nor are plants of *Azara integrifolia* variegata or *Othonna japonica*. *Choisya ternata* on three aspects—north, west, and south—is fresh, green, and vigorous; and *Greyia Sutherlandi*, though out to the ground, is otherwise in good condition, its crowns and roots being fresh and plump.—S.

Dendrobium Wardianum.—There will shortly be a fine display of this showy Orchid in the Pine-apple Nursery. The plants have for a long time past been subjected to cool treatment, having been hung up in a house occupied by *Solanums* and other plants. This has had the effect of thoroughly maturing the pseudo-bulbs, and the plants promise to bloom well in consequence.

Lilac Charles the X.—A good display is made by this Lilac just now in Messrs. Veitch's nursery at Chelsea. It is, without doubt, the best variety which we have for early forcing, and by proper management its flowers may be rendered quite white. The plants in question are bushes about 2 ft. high, and as much through, and the number of blossoms which each plant bears is almost incredible. They are grown in 6-in. and 8-in. pots, sizes in which they can be used with effect for dinner-table or room decoration. Associated with them are some very fine Tulips and the lovely *Staphylea colchica*, which is likely to be grown henceforward very largely by florists for market, for the sake of its blooms in a cut state.

National Auricula, and Carnation and Picotee Societies.—A committee meeting of the southern section of the National Auricula and also of the Carnation and Picotee Societies, was held the other day in the Royal Horticultural Society's conservatory, South Kensington. Mr. G. F. Wilson in the chair. Judges were nominated for both exhibitions, and the financial affairs of the Society were discussed. Although it is expected that most of the old subscribers will continue to support these societies, there are from various causes some certain to fall off annually. The committee trust that a sum of £10 10s. will be raised for each society by an appeal to those interested in these popular flowers, of which they have taken

special charge. Mr. Dodwell, the financial secretary, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W., kindly offers fifty seeds saved from his choicest named Carnations and Picotees, to each new subscriber of £1 ls. to the Carnation Society, or to any old subscriber who will add an additional guinea to his or her subscription.

Imported Pine-apples.—Large quantities of excellent Pine-apples have lately made their appearance in Covent Garden Market from the Azores. They are of good size, well ripened, and remarkably cheap, really good fruits being sold at prices as low as 10s. each.

Pavetta borbonica.—This is an excellent fine-foliaged plant for room decoration. Like the well-known *Ficus elastica*, it is erect in habit, and its leaves, which are deep green and netted with dark veins, with a bright red midrib, are thick and leathery; therefore, they can be easily cleared of dust, which is unavoidable in rooms. We lately saw good plants of it in Messrs. Carter & Co.'s nursery at Forest Hill.

LINDEN'S "ILLUSTRATION HORTICOLE."

A DOUBLE number of this admirably illustrated periodical, consisting of parts 7 and 8 of the 25th volume of the work, has just reached us, nearly six months behind time, as these parts should, in ordinary course, have appeared during the months of July and August of last year. The delay has been caused by the serious illness of the editor M. Edouard André. The remaining parts of the 25th volume are to appear at short intervals, and it is to be hoped that the numbers of the 26th volume will be published regularly on the 15th of each month. The double number just received contains the following coloured plates:—A single plate of *Phoenix rupicola*, a most beautiful Palm; a double plate of exquisitely beautiful varieties of erect-flowering Gloxinias, raised by that king of Gloxinia growers, Mon. J. Valeraud, of Asnières, near Paris, and representing the most remarkable and distinct of the many fine hybrids raised by himself, and shown during last autumn at the Paris International Exhibition. They are named as follows:—1, Lucien Linden; 2, Notaire Moens; 3, Marquis Chennevières; 4, Madame A. Lavallée; 5, Duc de Sutherland; 6, Madame P. Joigneaux; 7, Prince de Galles. A double plate of a fine new *Caladium* raised by M. Bleu, so celebrated for the improvements which he has been so fortunate as to make in this class of handsome-foliaged plants, and named Mon. J. Linden. A single plate of a new and beautiful cool stove shrub with large, pure white, tubular flowers, with yellowish throat, somewhat resembling in shape those of *Allamanda nerifolia*, and named *Coutaria Scherffiana*. This is one of the many valuable plants brought back by M. André from New Grenada in 1876, and since flowered by M. Linden at Ghent. It should be a great acquisition to our collections of stove plants. A single plate of a pretty *Bromeliad*, with small blue flowers, named *Tillandsia dianthoides*, but which also seems to own the following varied appellations:—*Pourretia seranthes*, *Amalia erisnicola*, and *Anoplophytum dianthoides*. It grows as an epiphyte on the branches of trees in Brazilian forests. A single plate of a graceful terrestrial Orchid, *Dendrochilum filiforme*, also known as *D. glaucum*, a native of Manila, whence it was introduced as far back as 1836. Why such plants should now be figured we are at a loss to understand. The number contains also several interesting and well written articles on variegated-leaved Pelargoniums, herbaceous plants at Kew, the flowering of *Vriesia guttata*, Alpine plants as grown at York and Edinburgh, the hybrid Pelargoniums of M. Lemoine, of Nancy, *Dendrobium superbiens* of Herr Reichenbach, on the Perret system of greenhouse heating, and an interesting paper on the shrubs and trees cultivated on the French shores of the Mediterranean Sea.

W. E. G.

"Vilmorin's Album of Forage Grasses."—Messrs. Vilmorin, Andrieux, & Co., Quai de la Mégisserie, Paris, have just issued this noble book, the publication of which is one of the most important of the many services they have rendered to horticulture. The work is designed to show all the forage Grasses printed in colours and shown life-size on large pages. With the aid of this work any one interested in meadow Grasses can at a glance identify the various species. At the end of the book there are a number of pages blank whereon may be placed either drawings or dried specimens of new or newly-employed forage Grasses.

Garden Pegs or Labels.—There is still a want waiting to be supplied in garden markers, and I should be glad if either Mr. Maw (who could do it most easily) or some other maker would supply it. Growers of herbaceous plants require a great many permanent markers. If there were pegs with numbers, say from one to fifty, in

bundles, they could be used without the trouble of writing, the numbers being recorded for identification in the garden catalogue. Mr. Maw's markers might be cast with progressive numbers without interfering with their ordinary use, and would thus be doubly valuable.

—BROCKHURST.

THE TURNIP GALL WEEVIL.

(*CENTORHYNCHUS SULCICOLLIS*).

THE weevil which forms the subject of this article is fortunately not so injurious in its habits as those to which attention has already been called; still the injuries which it commits are very extensive, and in the event of the insect being very abundant some year, cultivators of Cabbages and Turnips might be seriously inconvenienced by their attacks; under any circumstances, however, this beetle must be classed amongst the garden destroyers. The grubs of this insect form the wart-like galls frequently found on the roots of Cabbages and Turnips, which vary in size from that of a large shot to a knob as large as the end of one's finger. In the larger warts several grubs may often be found, whilst the smaller ones contain only one. It is difficult to suggest any means of destroying this insect. If in great numbers it might be worth while to collect the perfect insect by picking them off the plants by hand

as soon as they make their appearance on them, and before they have laid their eggs. Partridges and, I have no doubt, rooks and other birds will kill numbers of the grubs in fields of Turnips, and probably various birds kill many in our gardens. The weevils are frequently found on flowers in hedges and waste places from the end of April to the beginning of September. When alarmed they immediately feign death, and contract their limbs and antennæ, so that they do not in any way resemble a living insect. As soon as the roots of the young Turnips begin to swell, the females, with the assistance of their long beaks, pierce the skins of the roots and deposit an egg in each hole thus formed. The eggs soon hatch, and the grubs commence feeding on the root. The puncturing of which by the parent insect, perhaps accompanied by some irritant fluid, or the action of the grub in feeding, in some way which is not at present understood, causes the tissues of the root to form a gall over the grub, much in the same manner as Oak Apples, and galls are produced. The grubs continue living in the galls until they are fully grown, which probably

Centorhynchus sulcicollis.

does not occupy more than a few weeks. They then eat their way out, and descending into the ground, become chrysalides, having previously formed cocoons round themselves. The time which the changes of this insect occupies is uncertain, as the grubs have been found in the galls as late as the beginning of spring. Probably there is more than one brood, the transformations of the first being (as is often the case) much quicker than the last, the grubs of which do not become chrysalides until the following spring. The beetle is about one-eighth of an inch long, and is broad in proportion to its length; it is black and glossy in colour, very sparingly covered with fine, white, depressed hairs. The head is produced into a long, slender, curved beak or snout, about the middle of which the antennæ are placed; they consist of twelve joints, the four terminal ones forming a club, which is placed at an angle with the basal ones. The thorax is strongly punctured, much narrower in front, the sides somewhat hollowed where they converge with a broad groove down the middle. The wing cases have ten well defined, incised, longitudinal lines down each; legs tolerably long with thickish thighs. The grubs are about two-tenths of an inch long. When full grown they are fat and legless, white or flesh-coloured, with a yellowish head. They are usually in a somewhat curled-up position within the gall.

S. G. S.

THE FRUIT GARDEN.

THE CULTIVATION OF CRANBERRIES.

I OBSERVE IN THE GARDEN FOR NOV. 16 (p. 435) some rather elaborate directions for establishing Cranberry beds, including artificial irrigation. I can assure those who desire to cultivate that very excellent winter fruit that they may reach their end in a far more simple way, at all events in a healthy district, as this portion of the Weald is. I have had, for a good many years, two flourishing beds of the large-fruited Cranberry, which has gone on fruiting abundantly from December till the end of spring, and pushing its trailing shoots in every direction, with no other soil than the natural one, and no more irrigation than what the rainfall yields. One of these beds stands on a dry, sandy hill, while the other, at a short distance off, is more flat and moist, and I should imagine that the success of both would have been about equal had not the latter one been allowed to be too much overrun with Heather, Brambles, and other intruders; now that they are cleared this bed seems to be starting fair with the other one. I fancy the truth to be that where Heather is the weed of the soil the Cranberry will probably not refuse to grow. The Heather (*Calluna*) is always pushing out its growth among my Cranberries, and has to be kept back, while, on the other hand, the long shoots of the Cranberry are extending themselves among the masses of Heather and Heath which fringe one of the beds.

A. J. BERRSFORD-HOPE.

Bedgebury Park, Weald of Kent.

WINTER-DRESSING FRUIT TREES.

WHEREVER fruit trees are much subject to the attacks of aphides, scale, Moss, or Lichen, a suitable winter dressing will be beneficial. For the eradication of Moss, fresh lime is the best and cheapest material to apply; it may be dusted on when the branches are slightly damp, or it may be applied in a liquid form through the syringe or garden engine. In either case a fourth part of soot may be added to it. Soot in any shape is a capital stimulant for fruit trees, and might with advantage be much more extensively used than it is, either as a top-dressing to the roots or as an insecticide. When applied in a liquid form, it should be strained, just previous to being used, through a piece of canvas; otherwise the syringe or engine may be rendered unserviceable. For the destruction of scale and aphides, Gishurst Compound, in the proportion of 8 oz. to the gallon, may safely be used dissolved in soft water. The compound, as I think, the best plan is to thicken the liquid compound with lime and soot, and a couple of good handfuls of sulphur per gallon till it has the consistency of ordinary paint, and then put it on all the branches of the trees with a soft brush, rubbing it well in on the old wood, but passing over the young shoots with a lighter hand, so as not to disturb any of the buds, drawing the brush along in the direction of the buds only without any reverse action. It has been stated that to simply wash the branches of the trees with the liquid compound without any thickening ingredients would have the same cleansing effect. I have tried both ways, and the conclusion at which I have arrived is that the thicker mixture has a more lasting and beneficial effect than the thin one, and as one can be applied nearly as quickly as the other, and there is not much difference in the cost, I should recommend a continuance of the old system.

E. HOUDAY.

SAUCERS FOR STRAWBERRIES.

THE great evil arising from the use of these is having them too large, whereby they hold as much water that the plants standing in them are drowned, and the roots, therefore, instead of being healthy and active are just the reverse, as must, of necessity, be the case when the soil is always in a wet, sodden condition. During certain stages of their growth Strawberries will stand almost any amount of water, but, like most other moisture-loving plants, they only do really well when it passes freely off, and there can be no question that if they could only be kept uniformly wet enough by going over them oftener than time in most places will admit of, they would succeed better without saucers than with them. Whenever I use them, I always have such as are made for pots a size smaller than those in which we grow Strawberries, (6-in.) and then the pots do not quite reach the bottom of the saucer; most of the water in that way which they contain is drawn up by capillary attraction, and is all taken out

and made use of during the twenty-four hours. When this takes place I never consider that plants of this class receive any harm, as the supply which they get is not excessive and is perfectly natural, but when they have more than they can absorb, or make use of, the excess soon makes itself known in the shape of enfeebled health.

It will be found a good plan where saucers are larger than they should be, to nearly fill them with sandy shingle or broken-up horse manure mixed with leaf soil, or anything of that kind that will not get muddy through being so much saturated with water. By managing in this way, plants standing in large saucers are almost, if not quite as well circumstanced as those in others of smaller size, as so long as the earthenware of the pot remains in contact with the moist body of matter beneath, it will absorb water from it and give off part of it to the roots. The best place I ever had for pot Strawberries when being forced was along the wall of a house having a hip roof, and instead of this being finished flush on the inside, as is generally done, the roof was carried to the back, where the plate rested on $4\frac{1}{2}$ in. work, carried three courses high for that purpose. The wall being 14 in. thick, gave us a shelf about 8 in. wide, which was formed by a coat of cement on the bricks, and, by running a fillet of the same along the front, water always stood there, and, to prevent this running down and staining or disfiguring the wall in the house, or being too deep for the welfare of the plants, a few pieces of small gas pipe were let in to conduct it to the outside, so that it never stood beyond a certain level, however much might be given. Were I building pits or houses again, and could have my way, I should always finish them in the same manner, as shelves so formed are the very best positions for Beans, Strawberries, and many other things we have to grow and supply; besides which, there is much space gained and less timber required for wall plates, and there is, therefore, a great advantage in such an arrangement in many ways. Pots placed on a wood shelf suspended in the ordinary fashion are fully exposed to the desiccating influence of the sun, and with a constant play of air around them, there is always much difficulty in maintaining the soil within them in anything like an equable condition of moisture, and if this be not done, red spider is soon rife, and spreads with the greatest rapidity. With a wall forming a shady back ground, and a shallow sheet of water throwing off vapour under the foliage, these insects have no chance, and seldom put in an appearance, as they are mostly found only where plants from any cause are insufficiently fed.

S. D.

PINE HOUSES.

PERMIT me to say, in reply to Mr. Baines (p. 131), that I never stated that good, pure loam was unsuitable for Pines. I said Mr. Baines was wrong in saying fresh loam was "the only soil" suitable for them, and my reason for saying this was that I have seen Pines grown well in many varied composts, and have so grown them myself. As to Mr. Baines' advocacy of a lean-to structure in preference to the span-roofed form, I cannot do better than quote Mr. Baines himself in support of my opinions. IN THE GARDEN for January 1876, he writes as follows regarding plant and fruit houses:—"For plants of any description there is no form of house equal to a span-roofed one, placed, if possible, with the ends standing north and south. In this case the inmates have little disposition to become one-sided or drawn; on the contrary, they maintain their natural character, and possess a robustness of health only attainable when grown under the influence of a maximum amount of light. Further, I may add, in reference to this form of house, that there is nothing equal to it, either as regards the health of the plants to be grown therein, the strength of the structure, or the cost of construction. Under no conditions is it advisable to build lean-to houses, not even against existing garden walls that are no higher than the top of the roof lights, except for Vines, Peaches, or Cucumbers, that, from their nature, need roof-training and every ray of light that passes through the glass." I may add that I do not go quite thus far.

Wortley.

J. SIMPSON.

Forcing Early Strawberries in Pots.—Having now grown *Vicomtesse d'Haricot* *De Thury* Strawberry for the earliest forcing sort for several years, I find it by far the best which I have ever tried. The *Black Prince* will, perhaps, come in a week earlier in March, but it is subject to mildew, and does not set so freely as the *Haricot* *De Thury*, nor is it so finely flavoured. For other two successive early varieties, *President* and *Sir Joseph Paxton* do well with me; and last year the *Grosse Souvée*, which I can recommend as a good early forcing sort. The early forcing Strawberries are grown here in pits, where the shelves are near the glass. The shelves are of iron and are about 1 in. deep, so that when the sun begins to have some strength in March and April they are filled with weak liquid

manure at times. This keeps the roots of the Strawberry in the bottom of the pots well supplied with moisture, and causes the fruit to swell to a better size, than when the plants are grown in the usual way.—WILLIAM TILLEY, *Welbeck*.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Potting.—The particular time for potting the principal portion of the occupants of plant stoves will depend upon the temperature kept up in them. Where the heat maintained through the winter months is consistent with the requirements of such species of plants as need the most warmth, they naturally begin to grow considerably earlier than where less heat is used, and, on this account, the general potting will need to be done sooner than where the temperature is lower and growth commences later. In all cases where plants have been cut back, and time allowed for their breaking into growth, previous to being partially shaken out and re-potted, it is not well to delay their removal until too much shoot development has taken place, as when that occurs the severe check given by the partial shaking away of the soil, and the unavoidable disturbance and destruction of the roots accompanying it has the effect of stopping many of the young growths; consequently, all that were cut in about the commencement of the year will by this time be in a condition for potting, first warming the material so as to make it fit to come in contact with the roots of plants grown in heat. Most hard-wooded stove subjects, from their naturally more rapid growth than that which takes place in the case of the generality of greenhouse plants of a like character, need a good deal more water, to meet which provision must be made by using sufficient sand in the soil to admit of the moisture passing freely off; decomposition of the fibrous matter contained in the potting material used for plants grown in stove heat is quicker than in the case of those in a lower temperature, and this tends to reduce the soil to an adhesive, sour condition, to avoid which it is well to use it in a rough, lumpy state, proportionate to the strength and size of the plants, and also the size of the pot in which each is placed. I have long been convinced that with very few exceptions the loose system of potting carried out in the cultivation of many plants in times past was a mistake, its direct tendency being to produce long, weak shoots much fewer in number than where in potting, the soil is compressed sufficiently to afford a more holding medium for the roots. Through being in this way alike in its effects, I have found it better to dispense with the use of leaf-mould in the case of all but a few of the quickest-growing, soft-wooded subjects, for though when used for plants of a harder, slower-growing character, it stimulates rapid leaf and shoot development, yet proportionately fewer flowers are produced. Most free-growing stove plants, too, especially those that are of a deciduous character, have a greater disposition to bloom when grown in loam alone than in any admixture of loam and peat.

Diacenas, Cyanophyllums, Sphærogynes, Crotons, Pandanaceas, and Piantanus.—Large plants of these that require it may now be taken out of the pots which they are in; a portion of the old soil should then be removed, fresh material added, and the plants returned to the same pots, or larger if needed. In the case of these the soil should also be rammed tolerably firm. When all plants that at present want potting are finished, those not yet started and intended to succeed the earliest, should at once be attended to, cutting back those that may require it, thoroughly moistening the soil of any that have been allowed to get dry, and daily syringing overhead and keeping them sufficiently warm to induce growth.

Plants Grown on Trellises.—It is nearly always desirable in the case of these to fix the trellis at the time of potting, keeping the existing branches well to the base, for if not properly furnished at the bottom early in the season it is difficult afterwards to cover it, and it should always be borne in mind that the trellis is merely a means for supporting plants, the natural habit of which is such that they cannot well be grown as pot specimens without it. The young-growing shoots should not, however, be kept continuously trained down with a view, as is sometimes supposed, of giving a tidy appearance, as in that case, instead of their extending freely, as they will when allowed to assume an erect position, there is a continual disposition to break out at the lower eyes, which crowds the specimen with a quantity of weak, useless shoots.

Temperature, &c.—The temperature may now be raised some 6° or 5° in the daytime. It is frequently urged that it is wrong in practice to start plants into growth until the spring is so far advanced

as to afford more daylight, but with the majority of plants that require a stove temperature if this course be followed the length of time which they can be had in flower is very much reduced, and in a thoroughly light, well-constructed stove, with the plants as they should be at this season, elevated with their heads near the glass, there will be no weak growth.

Achimenes.—It is now time to start a portion of these; if kept, as they winter best in the old soil, in a dry state and sufficiently warm, they should now be shaken out and placed in pans well drained and filled with loose, light soil. When they have made a little growth they may be transferred to the pots in which they are to flower without breakage of the young, newly-formed fibres, which would be done if material of a stronger character were used. It is well to keep some in a dormant condition until later on for blooming towards autumn.

Gloxinias.—More should now be started. In the case of small bulbs raised from leaf cuttings last year they may first be put in little pots and moved into larger ones when they have made some growth. Where raised from seed this should be sown, pressing the surface of the soil moderately firm and quite smooth, with just enough fine, sandy, sifted material to cover the seeds. Set the pots at the warmest end of the house until vegetation takes place, and then they should be kept close to the glass.

Marantas.—Large specimens of these are not so useful for general decorative purposes as smaller ones, and where plants exist that it is desirable to divide, this may be done at once. Marantas are often grown in a higher temperature than they absolutely require, the result of which is that if taken out of the stove, even for a short time, they flag. This is particularly the case when they are used for exhibition, a purpose for which they are totally unfit till the summer has become somewhat advanced, which gives time for their full development without being hurried. They will grow in either peat or loam.

Medinillas.—In a large stove few plants are more effective than these. Plants of them that have been kept somewhat dry at the root and comparatively cool through the winter should now be encouraged to flower; if they have been grown under conditions such as give the necessary solidity to the wood and leaves, they will bloom profusely, not only from the points of last summer's shoots, but likewise from the lower portion of the branches.

Gardenias.—These, where kept sufficiently warm, will now be beginning to flower; those brought on early are sometimes liable to drop their buds, the best preventive of which is to avoid the extremes of an over-dry or too moist condition of the roots, and not to keep them too moist overhead.

Nepenthes.—It is useless attempting to grow these unless they can have a brisk, moist heat. They need very little root room, and there should never be an attempt to reduce the soil from the balls which the roots have already occupied. It is now time to pot any that need it. The material in which they require to be grown ought to be nothing but the fibrous portion from the best Orchid peat mixed with a third or a fourth of chopped Sphagnum, some sand and pot shreds, or charcoal being added. The slightest disturbance of the roots is much more injurious to them than to almost any other plants with which I am acquainted.

Sarracenas.—An intermediate temperature is quite sufficient for these; in fact, they do no good at all if grown in too hot a place. It is essential that the roots be placed in new soil every year, and equally necessary is it that the potting be done at this time before growth commences. Material composed of about equal quantities of good fibrous Peat and chopped Sphagnum, with the addition of a good amount of pot shreds and some sand, will answer for them.

Forcing Pit.

There must be a continuous introduction into the forcing pit of the different subjects required to be brought on into flower for conservatory decoration, cut bloom, &c., regulating the quantity proportionate to the demand; more bulbs, such as *Hyacinths*, *Tulips*, *Narcissi*, *Lily of the Valley*, and *Scillas*, together with *Hoteia japonica*, *Rhododendrons*, *Kalmias*, *Lilacs*, *Andromedas*, double-flowering *Plums*, and *Deutzias*, should be brought in.

Solomon's Seal and *Dicentra spectabilis*.—These are most useful for supplying cut bloom through the spring, or for conservatory decoration; but to flower the *Dicentra* well, it must not be hurried, or placed whilst being brought into bloom where there is not plenty of light, as it draws up weakly.

Spirea palmata.—Beautiful as this plant is when grown out-of-doors, it is even of still more service cultivated in pots, but not submitted to too much heat, or the fine colour of its flowers will be absent

As a conservatory subject, mixed with the numbers of light-coloured blossoms that prevail at this time of the year, there are few plants that produce a more agreeable contrast.

Ferns.

The potting of these should, unless in exceptional cases, always be carried out just before the top growth begins to move; if later, the fronds next produced are almost certain to come more or less deformed. For Ferns a porous condition of the soil is an absolute necessity, but I have found that it is better to mix it with charcoal, potshreds, or broken coal cinders than to add to it very much sand. In the cultivation of Ferns, particularly those of large growth, with the exception of any that have creeping rhizomes, it is better to confine them to pots much smaller proportionately than the generality of other plants, as with the tree kinds especially there is ordinarily a disposition to outgrow the limits at command. This is the more advisable, as the requisite vigour can always be secured by the use of manure water.

Orchids.

Potting and Top-dressing.—It is now time to commence potting such of these as require it. A little observation as to the nature of the roots of the plants, clinging as they do to whatever substance with which they come in contact, at once shows that they should never be moved from the pots, baskets, or blocks which they occupy until there is an absolute necessity for it, as, with the greatest amount of care possible, they cannot be moved without considerable breakage, which correspondingly interferes not only with their blooming during the coming season, but also with the growth which they make; nevertheless, it does not do to let them remain in material that has become effete and too far decomposed, or in pots which they have outgrown; especially should this be avoided in the case of such kinds as *Cattleyas* and *Lælias*. Where the growths have so far extended that the roots, instead of being inside the pots, cling to the outside and have little or nothing to sustain them, the pseudo-bulbs formed under conditions of this sort will almost invariably be found deficient in size, and the leaves to have a sickly appearance. All reasonable care ought to be taken not to break the roots more than is unavoidable in removing them from the old pots, and also in placing the material about them in the new ones. From the nature of the roots of Orchids, it becomes apparent that nothing but the most enduring materials should be used for potting them, such as the best fibrous portion of peat, with clean sphagnum, and pot-shreds or charcoal; the two former in something like equal proportions. This compost will suit the majority of *Cattleyas*, *Lælias*, *Oncidiums*, *Epidendrums*, *Cypripediums*, *Angulosas*, *Brassavolas*, *Chysis*, *Coclogynes*, *Dendrobiums*, *Lycastes*, *Huntleyas*, *Gongoras*, *Odontoglossums*, *Miltonias*, *Trichopilis*, *Stanhopeas*, and others of similar habit. Keep the plants sufficiently, but not too much, elevated in the pots, press the material sufficiently firm, and slightly moisten the surface, which should be left tolerably smooth and even. In all cases at once apply whatever sticks are necessary, to prevent the plants from shaking about when being moved, until the new roots have got sufficient hold to support them. *Aerides*, *Saccolabiums*, *Vandas*, the thick-rooted *Agrostoms*, *Renantheras*, and *Phalenopsis*, are even still more impatient of their roots being disturbed than the foregoing. For these little beyond sphagnum is often used; press it moderately firm, and secure the plants with sticks and ties, as when grown in pots; those that are cultivated on blocks and in baskets fasten in like manner with wire or bast; I do not like more of the former being employed than can be avoided. The same applies to *Dendrobiums* and all similar subjects suspended in baskets. For *Sobralias*, *Phajus*, *Calanthes*, *Zygopetalums*, *Peristerias*, and *Ansellias*, some growers prefer loam, others peat; whichever is used it should be of the best description, and have sufficient crocks or broken charcoal, with a little sand intermixed. After potting, it is well to at once raise the temperature a few degrees, being careful not to give much water until the growth of the plants, accompanied by more warmth, makes its application necessary.—T. BAINES.

Flower Garden.

Outdoor operations in this department will have, for the most part, come to a standstill; but such is not the case indoors as propagation, seed sowing, potting off, &c., may now be proceeded with as fast as circumstances will allow, in order that the labour may be concentrated on outdoor work as soon as the weather becomes favourable. Most kinds of large-growing, fine-foliated plants may now be sown in heat in shallow boxes or pans, which should be filled within 1 in. of their rims with light, sandy soil; cover the seeds very thinly and the boxes or pans with glass till germination takes place, which will be in a few days if placed in a temperature of 60° or 70°. The following are amongst those which we have found most

useful, and all of them will make fine plants by May if sown as indicated:—*Azalea lophantha*, *Cannas*, *Ricinus*, *Solanums*, *Ferdinandias*, *Eucalypti*, *Wigandias*, and, of the smaller-growing kinds, the best are *Chamæpoux dicantha*, *C. Casabonæ*, *Centaureas*, *Amarantus*, *Perillas*, and *Salvia argentea*. With regard to the propagation of bedding plants a plan of the proposed planting should be sketched, and a computation made of the number and kinds of plants required for each bed or border. Without some such method the probabilities are that at planting time there will be an overplus of some kinds and a corresponding lack of others, which by timely forethought may be prevented. As summer bedding plants *Abutilons* have not yet gained that prominence which they are destined to do; of course some of the varieties are not suited to the work, as they grow so rampantly and fail to flower when planted out, but others, such as *Boule de Neige*, *Lemoinei*, *Reine d'Or*, and *Duo de Malakoff* flower in profusion, and either as single specimens to break the formality of even surfaces or as masses for centres of large beds they cannot be excelled, and being as easily propagated, grown, and wintered as the hardiest *Perlargiums*—of which we have had a surfeit—they deserve to take the place of some of these. *Lantanas*, too, should be again brought to the front, and they will doubtless be so by all who had the good fortune to see the magnificent beds of them during the past summer in the Park Monceau and the Luxembourg Gardens at Paris; as seen growing there no *Perlargium* could excel them, either for profusion of flower or brilliancy. If a few stock plants were now introduced into heat they would produce abundance of cuttings in two or three weeks, and these would make good plants for putting out in May.—W. W.

Auriculas.—We have now surface dressed the pots, and find that a large portion of the leaves have suffered from the severe frost, which has reduced the crowns to a hard tuft of short, bristly foliage. Cleanliness is an important element in success; therefore, besides seeing that no aphides are left upon the leaves, the pots should be washed, as they get covered with green mould in the shady place in which the plants have been grown. When the surface soil has been removed a good opportunity to take off all offsets that are ready is afforded; these should be cleaned of superfluous leaves and then be inserted in soil composed of equal parts loam, leaf mould, and sand, using small pots. I have been most successful with offsets at this season than at any other. The pots may be placed in a cold frame near the glass. After the large plants were surface dressed they were placed in the frame again. There are a good many dead leaves round the crowns of the choice *Alpino* varieties planted out-of-doors; these should also be removed and some fine soil placed over the exposed stems.

Garnations and Picotees.—One of the principal growers of these, writing from Yorkshire, says that he had not seen his plants (that were potted in the autumn and placed in frames) for many weeks; the frost had been intense, but the glass was covered with snow, which is a first-rate protection for anything underneath. When the lights were removed the plants were found to be in perfect health. We remove the glass lights from our plants every day when it does not rain. Plants in beds or borders of the hardy varieties, including *Cloves*, require to be looked over and the soil made firm round their stems after every severe frost; even the labels are thrown out of the ground by the frost, and must be put right again during these operations. Any weeds to be met with should be removed. A surface dressing of fine, rotten stable manure is beneficial to plants in beds.

Dahlias.—If there be no convenience for cuttings of these except hot beds greater watchfulness will be necessary, as they are more liable to damp off in these than in heated pits. See that fresh cuttings are put in to replace those that have failed. Remove the rooted plants from amongst the unrooted cuttings, and place them in a compartment where more air can be admitted.

Hollyhocks.—The treatment for these is very much the same as that described above for Dahlias, but the plants are much more readily injured if they receive any check as regards growth. Remove the rooted plants from the frame, and place them in a cooler place near the glass. They must be potted into larger pots when they have made a little growth. If stinted for pot room or irregularly supplied with water, they will start into premature bloom.

Pansies and Pinks in Beds.—Our plants of these were put out rather late, and they certainly do not look well; the Pansies have suffered most severely from the frosts, and the Pinks have not escaped. Our collections comprise the choicest named sorts, and many varieties that have the best blooms are the most tender, and if extraordinary care be not taken with them, they will disappear from the collection. Some of the plants were thrown quite out of the ground by the frost, and at least a third of the labels were upset; the latter have been replaced, and the plants made firm, and blank spaces filled

up with others. The frost seems to have been too much for slugs, of which there is no trace on the beds.

Phloxes, Delphiniums, Pyrethrums, &c.—These seem to be safe where they have been allowed to remain in the beds where they flowered the previous season; had they been taken up and parted, as is sometimes done, in the autumn, some, doubtless, would have been killed. As it is a few of the Phloxes that were exposed without any mulching seem to have been injured if not killed. If the plants are not to be lifted and divided, the surface of the beds should be mulched with rotten manure and good loam in equal proportions, to the depth of 2 in.

Polyanthuses.—I have not yet found it necessary to surface-dress these. The plants were grown in the open ground until September or October, and therefore they do not exhaust the soil in the pots to a great extent from that time until now. I find green fly to be a troublesome pest at all seasons, and it must be destroyed in order to give the plants a chance. It is only the very choicest named varieties that are grown in pots, the others make a fine display in beds or borders. It is best to replant annually, or if this has not been done, the beds must be surface-dressed with rich soil.

Ranunculuses.—Few people now grow these, and fewer still possess complete collections of them, a circumstance to be regretted, as a place might readily be found for them in every garden specially devoted to spring flowers. The tubers should be planted as soon as the ground is in good condition to receive them; and they like a deep, rich, open soil. Plant them in rows 1½ in. apart, and the crowns should be 1 in. below the surface of the ground, with a little sand over and under them.—J. DOUGLAS.

Indoor Fruit Department.

Pines.—These are showing the effects of the protracted frost most plainly; hard firing, dark days, and the impossibility of giving air, are inducing a lanky growth, which, under the circumstances, is quite unavoidable; therefore, use no more fire heat than is absolutely necessary till the frost disappears. An over-moist atmosphere during such weather is also detrimental, because no air can be given to keep the same in motion, and the plants are therefore compelled to absorb it whether they require it or not. It will thus be seen how difficult it is, and what care is required to hit the happy medium in order to keep the plants in sturdy condition. Watering also requires close attention, as many Queens will now be throwing up their flower stems, and these, if once allowed to get thoroughly dry, will either have irregularly-swelled tips, or fine shows produce but poor fruit. Especially examine those in close contact with the pipes, for with such constant and hard firing, they will require water twice for the others once. Succession plants potted early in autumn will be getting pot bound, and should have a shift into fruiting pots as soon as convenient, otherwise the plants will fruit prematurely, more especially if they have been allowed to get dry. Suckers from the smooth Cayenne, and other winter-fruited kinds, should now be potted in 6-in. pots, and plunged in a bottom heat of 85°. As a rule, if the soil be moderately moist at potting time, no water is necessary till root action has commenced, but the soil should never be allowed to get dust dry. The smooth Cayenne produces but few suckers whilst the plant is fruiting, but it throws them out most freely from the old stools—i.e., if the latter be shaken out, the older roots cut off, together with the foliage, and the stems potted in 8-in. pots, and plunged in a bottom heat of 90° or 95°. The same treatment is applicable to any other variety where stock is required.

Vines.—I happen to be one of the very few who do not believe either in the utility or profitableness of pot Vine culture, but this season, I am willing to admit, that the advocates of the system have the best of the argument, for forcing so far has been up-hill work, and much injury is sure to accrue to permanent Vines, by—as it were—forcing against time, and in the face of such fearful odds as continued frost, keen easterly winds, and leaden skies, for I verily believe there has not been six hours' sunshine since the beginning of the new year. The Vines sadly want sunshine, for the shoots are near skin to straw, both in size and colour. Now that we may fairly expect a change, diligence as regards ventilation when the sun shows itself will soon effect a change for the better, but guard against cold draughts. Disbudding should be partially done as soon as the Vines are well broken, that is, the weakest duplicates should be taken off, and as soon as the branches can be distinguished they may be finally disbudded, leaving those with the most prominent shows; stop the shoots at one, two, or three points beyond the bunch, according to the space there is available for the full development of the foliage. Many growers have a disposition to stop the laterals too persistently, and, as we believe, suffer for their pains proportionately, especially when such stopping or pinching is done in the earlier stages of growth, before the roots have got vigorously at work.

This untimely pinching, together with high night temperature, if the weather be ever so severe, soon tells seriously on the Vines, either by the production of long tendril-like branches, which never finish off or look well, or else by shanking just at the time when one thought they were all right. Inside borders, during the time when the fruit is ripe, are apt to get very dry, and several waterings are necessary, ere the entire mass of soil gets soaked throughout, which is, however, necessary to obtain the best results; therefore, if the drainage be ample do not be afraid to overdo it in this respect; and if the water can be used at a temperature of 70° or 80° all the better; at any rate, the chill should be taken off at whatever stage of growth the Vines may be in. Vine eyes may now be put in—single buds with the under part of the wood cut off—and planted firmly in light fibrous loam; the pots should then be plunged in a bottom heat of 80° till roots are formed, after which they should be grown without bottom-heat in a moist temperature of 65°. Any Grapes still hanging on the Vines will require almost daily attention, in order to remove any decaying berries, and the air will have to be kept buoyant by the application of slight fires and ventilation. Cut them with a good piece of wood attached to each bunch, and place them in bottles of water in any dry room from which frost can be excluded. The Vines can then have the needful rest, an imperative requirement as regards success.

Peaches.—Owing to there not being a gleam of sunshine, artificial fertilisation must be practised as the blossoms expand; shaking the trellis will help to disperse the pollen, but better do it effectively by using a camel-hair pencil, going over the blossoms singly; keep the air dry but not arid, and the maximum temperature, without sunshine, should not exceed 60° with a maximum by night of 50°. Trees that have set their fruit may be partially disbudded, sparingly at first, in order that no check may be given. It is better to go over them half-a-dozen times, at intervals of a couple of days, and remove a few buds each time, taking care to leave a good one at the base and point of each fruit-bearing shoot, than to disbud all at once. Do not be in a hurry to tie them down to the trellis; none of them need be so fastened till all are finally thinned. As soon as the fruit is set, the syringe may again be brought into use, but till the weather is warmer and brighter, do not use it too freely. The borders may now require another watering which should be at least of the same temperature as that of the house. At the present stage a sudden chill, either from the application of cold water to the roots or draughty ventilation, would cause the fruit to drop. In succession houses, previous to the expansion of the blossoms, fumigate for two or three nights in succession, in order to insure freedom from fly whilst the trees are flowering. The above practice has now for some years kept our trees perfectly clean at this most critical time, when, if some such precautionary measure had not been taken, the worst consequences might have ensued through the attacks of green or black fly. The pruning of late houses should be no longer deferred, after which every scrap of wood, glass, floor, and walls, should be cleansed, as a preventive against insect pests. If winter dressing and cleansing be not attended to, summer troubles may be expected in the shape of red spider, thrips, mildew, and the like. Better, therefore, save both time, vexation, and the health of the trees, by anticipating such evils. The present winter has put many operations out of joint, and, amongst them, fruit tree planting, which ought not now to be longer delayed, more particularly indoor fruits; take, therefore, the first chance of accomplishing this. When done without wanton mutilation of the roots, Peaches and Nectarines bear this late removal better than most trees.

Strawberries.—Winter effects are observable at every turn, for Strawberries have made less progress during the last month than ever was known before, but surely a change is at hand; till then force very gently. Continue to fertilise the flowers as they open; keep the atmosphere on the side of dryness, but take care the plants do not get dry at the root, or they are certain to go blind, no matter whether they are fertilised or not. So long as the intense cold lasts keep the reserve stock in cold pits, dry and protected from frost, which cracks the pots even if it does no injury to the plants, as some think, an opinion which I am inclined to dispute.

Melons.—These may now be planted out if the plants are strong and the roots are lining the sides of the pots; otherwise nothing will be gained by planting so long as this unseasonable weather continues. A restricted rootspace is necessary to fruitfulness and early maturity. A bed 18 in. to 20 in. wide is ample, including drainage of about the same depth. A bottom heat of 75° is necessary, and if a moist one all the better, as, from the vapour-moisture thus communicated to the soil, less surface watering is necessary. Heavy waterings are soon resented, either by the entire collapse of the plants by damping off, or else by an over luxuriant growth, which never proves fruitful. Earth up the seedlings last sown, and, to prevent a spindly growth, keep them as near the glass as possible.—W.W.

THE KITCHEN GARDEN.

NEW POTATOES FROM OLD TUBERS.

Mr. GILBERT, of Burghley, practices a system of growing new Potatoes which may be of interest to some of your readers. In July, seed Potatoes or "sets" are selected from the out-door crops, and these are exposed to the light on shelves in a cool, airy place where they are not subjected to any excitement conducive to growth. In this way they are kept for at least twelve months, when they are planted loosely in shallow boxes of leaf mould, and are afterwards placed in a dark, heated Mushroom house or other heated structure, where they soon commence to form young tubers without attempting to produce leafy shoots. I saw some young Potatoes thus produced on December 15, 1878, and their quality was excellent. These had been obtained from "sets" saved in July, 1876, and kept from making any leaf growth until September, 1877, when they were planted and otherwise treated as above described. Each old "set" bore from one to three Potatoes fit for the table. One advantage of this system is that it may be practised by amateurs readily, since a warm cellar or a cupboard near the kitchen fire would afford sufficient heat to start the old tubers. The annexed illustration, taken from one of Mr. Gilbert's crop, is an exact copy of an old tuber which has produced four young ones. Not the least interesting phase of this plan of culture is the fact that new growths or tissues are formed without the direct leaf action, which is generally considered essential to such a process. B.

New Potatoes from Old Tubers.

Trebons Onion.—We see in *THE GARDEN* (p. 112) that this Onion is supposed to be of French origin, a statement which induces us to observe that this variety was found some twenty-five years ago in a small place on the Pyrenees called Trebons, near Luchon (Garonne), whence we got some seed for trial, and, as it has been found to be a variety of great merit, it appeared soon after in our catalogues. Although it is a very poor seeder we have, on account of its excellent qualities, been offering it in our lists since that time. If we remember rightly, it was awarded a first-class certificate at Chiswick some time ago.—VIL-MORIN, ANDRIEUX, & Co., Paris.

SEEDS AND SEED-GROWING.

It is scarcely time yet (February) for getting in the general rack of garden seeds, though in dry warm soil many kinds may be sown, at least by the end of the month, with great propriety. Now is the time to calculate and procure the quantities to be sown. Indeed, this should be seen to before the soil is prepared, so that ground intended for the various crops may be properly treated. In giving directions for choosing seeds, the general rule is to say how much of this, that, and the other thing will be required for a quarter of an acre, half an acre, and so on. Such advice only serves to puzzle. The fact is, no two individuals' wants are the same, and hence a selection of seeds which might fit one person very well would be of little use for another. What I propose is, to give as near the amount of space required by a given quantity of seed, and by this means each person will be enabled to calculate to a nicety the seed required for his own individual wants.

Beet—1 oz. will sow a row 50 ft. long.

Broad Beans—1 lb. will sow a row 60 ft. long.

French Beans— $1\frac{1}{2}$ lb. will sow 60 ft.

Carrots—1 oz. will sow 130 ft.

Cress—1 oz. will sow 20 ft. of a row 4 in. broad.

Leeks—1 oz. will sow a bed 5 ft. by 5 ft.

Lettuce— $\frac{1}{2}$ oz. will sow 50 ft.

Mustard—Same as Cress.

Onion—1 oz. will sow 40 ft.

Parsley—1 oz. will sow 50 ft.

Peas—1 lb. will sow 30 ft. of a drill 5 in. broad, of the small, and 36 ft. of the large sorts.

Parsnips—1 oz. will sow 100 ft.

Potatoes—1 peck will plant 100 ft, if the seed is good, and cut to 2 eyes to a set only.

Radish—1 oz. will sow 20 ft.

Spinach—1 oz. will sow 60 ft.

Turnip—1 oz. will sow 100 ft.

Cabbage, Cauliflowers, Savoy, and all the Brassicas should be got in packets, as a very small quantity of seed will raise enough for most gardens cultivated by amateurs; indeed, it is advisable to get the plants from the nursery or from some obliging friend, and so save a great amount of worry.

In some collections of seeds offered by enterprising seedsmen I have sometimes seen 3 oz. of Cabbage included for gardens of $\frac{1}{4}$ of an acre! Why, it is more than enough to raise plants for the whole ground; of Celery and all other vegetables not included above a moderate packet is sufficient. A mere pinch of Celery will raise hundreds of plants.

Concerning annual flower seeds, some of the best got-up seedsmen's catalogues afford a good deal of information, and to these I must refer the amateur in the meantime, until I treat of them in a chapter on flower gardening.

KINDS TO SOW.—It is not enough for the inexperienced to know the proper quantity of seed required to sow a given space, it is of greater importance to know what kinds to sow. The kinds named below have been fully proved by the writer of this, and he can therefore recommend them. Almost every variety recommended has been well proved, and I have carefully avoided anything savouring of novelty which has not been found equal or superior to older varieties. The inexperienced should not be led astray by the glowing accounts of new introductions, as a great percentage of really new vegetables are inferior to well-known kinds, and the really good are sometimes nothing more than old kinds renamed. At the same time

really meritorious novelties are occasionally introduced. In this selection I range the names according to their earliness.

BEET.—Dell's Dark Red, Nutting's Selected, and, for extremely thin poor soils, Egyptian Turnip, rooted.

BROAD BEANS.—Early Mazagan, Seville Longpod, and Broad Windsor.

FRENCH BEANS.—Negro Longpod, and Canadian Wonder.

BROCCOLI SPROUTS.—All depends on the strain; Greens or Borecole, ditto.

BROCCOLI.—Veitch's Autumn, Snow's Winter White, Purple Sprouting, White Sprouting, Leamington, Eleton's Mammoth, and Dilcock's Bride.

CAULIFLOWERS.—Early London, Dwarf Mammoth, Walcheren, and Veitch's Autumn.

CARROTS.—Sutton's Champion Short Horn, James' Intermediate, and Altringham; the Short Horn for earliest, and the Intermediate for shallow soils.

CABBAGES.—Little Pixie, small, but of the finest quality; and if planted close, will yield more for the table than the large-growing kinds, many of which we consider unfit for the table at all. Dwarf York, fine for sowing in April to keep up an autumn supply; sown at the end of July, and planted out in September, it is fit for use in April and May. The same may be said of Little Pixie. Enfield Market and Sugar-loaf are good larger sorts. The Drumhead kinds are unfit for a small garden, the dwarf being of better quality than the giant.

SAVOYS.—Sutton's Tom Thumb, very small, but of super-excellent quality, and if planted 1 ft. apart each way, will yield almost as

much as the larger kinds. Early Dwarf Elm is a good early sort, and Drumhead, a larger and later one.

CELERY.—Sandringham and Cole's Crystal among whites; Sutton's Sulham prize of pink varieties; and William's Matchless among reds.

VEGETABLE MARROWS.—Moore's Cream and Hibberd's Prolific.

LEKES.—Aiton Castle Giant for quality and size, and Musselburgh for hardness.

LETTUCES.—Cos varieties—London White and Paris White, Champion Brown.

CABBAGES.—Varieties—All the Year Round and Neapolitan.

ONIONS.—The Queen (very early), Danvers' Yellow, Blood Red, James' Keeping, for spring sowing; and Globe, Flat Tripoli, and Giant Rocca for sowing early in August.

PEAS.—Ringleader, Kentish Invicta, William the First, and Sutton's Emerald Gem for first sowings; Dickson's Favourite, Daniel O'Rourke, and Fabus Market Favourite for second; best of all, McLean's Wonderful, Champion of England (very tall) for third sowing; Veitch's Perfection, Ne Plus Ultra, Lynn's Marrow, William's Emperor of the Marrows, Hair's Dwarf Mammoth, and McLean's Premier for last sowings.

POTATOES.—Veitch's Early Ashleaf, Wonderful Red, Alpha, Early Rose, Snowflake, Dalmahoy, Walker's Early Regent, Paterson's Victoria, Sutton's Magnum Bonum. I strongly recommend beginners to fight shy of the more famous show kinds, as not a few are of very inferior quality, such, for instance, as the Old Handsworth's Early, very wrongly re-christened Porter's Excelsior. This is an inferior Potato to eat, although of fine shape.

RADISHES.—We advise amateurs to get their seed in mixed packets.

PARSNIPS.—Student, Hollow Crowned.

SPINACH.—Round, for sowing in spring and summer; Prickly, for sowing about the middle of August. New Zealand requires to be raised under glass, and transplanted early in June.

TOMATOES.—The Conqueror and Hathaway's Excelsior. They require rearing under glass, and after danger from frost is past, to be put in any vacant space of a warm wall. In cold districts they require to be under glass.

TURNIPS.—Early Dutch White, Early White Strap Leaf, Robertson's Golden Ball, Chirk Castle, Black Stone, and Laing's Swedish, for keeping over winter.

These varieties have always given satisfaction. It would have been very easy to have doubled or even trebled the list. Few amateurs require a long list, and more experienced growers will be able to add to this list for themselves. Sometimes a given variety of a vegetable will do well in one district and not in another, such as Peas and Potatoes. I would warn amateurs against being led astray by large vegetables—that is, kinds which grow large naturally, as the more rapidly the majority of vegetables are grown the tenderer they are. Half-starved garden produce is neither palatable nor wholesome; nor, as a rule, are giant varieties. Size and coarseness almost invariably go hand in hand; and as a matter of fact, it is not often that great, coarse-growing vegetables yield the greatest amount of real useful produce. For instance, the ground occupied with a coarse Drumhead Cabbage would produce three or four little Pixies, the united weight of which would equal the coarse one, and which would give the greatest satisfaction on account of their quality. It is the same with Potatoes, although there are more exceptions among them than among any other vegetables. Among Carrots, good strains of Early Horn are finer than any other kind, and the yield is not very much less than the coarsest kinds; indeed, is sometimes greater. It would be well if your readers who are acquainted with specially meritorious varieties were to add them to the above. The kinds named I can confidently rely on myself, but it is possible that some of them do not succeed as well under other circumstances; and any information will prove of the greatest value, not to amateurs only, but to many others.—"The Gardener."

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Veitch's Self-protecting Broccoli.—I cut good dishes of this on the 16th, 17th, and 18th of January, a circumstance at which I was surprised after experiencing 30° of frost. It was planted near a south wall, and received no protection whatever. Indeed, as its name implies, it is thoroughly self-protecting, and is, without doubt, one of our very best Broccoli. —H. PARR, Harrow Weald Park.

Effects of the Late Frost on the Cabbage Tribe.—It is curious to note the varying effects which the frost has had on vegetables which are usually considered to be about the same as regards hardness, but which is not really the case. Savoye are not injured in the least, whilst young plantations of Enfield Market

Cabbage are very badly so, and the old Cabbage stems, from which bushels of sprouts were expected, are completely killed. Purple and white sprouting Broccoli are as fresh as ever, and so are Brussels Sprouts and Cottagers' Kale, but the Green Curled Kale is much injured, and many will die outright. Veitch's new Protecting Broccoli is also much damaged, and so is Snow's and Osborn's, but Early Pensance, Sutton's Perfection, and Cooling's Matchless are unscathed. All the late kinds of Broccoli are comparatively uninjured.—W. W. H.

Climax Potato.—Having been informed last season that Climax was a remarkably good Potato, I desired my gardener to plant it largely, and the result is most disappointing, considering that I paid 7s. 6d. per bushel for seed. The crop was a heavy one, but the produce is really hardly fit to eat, being disagreeably sweet and watery. I should add the tubers were planted on a warm, dry border, with a gravelly subsoil, and that Rivers' Ashleaf, which we used up to Christmas and came off the same soil, was excellent. The tubers of Climax are so bad that no one in the house can eat them, and I purpose selling them for what they will fetch. My gardener attributes the result entirely to the late wet season. Is that so? Will some of your correspondents kindly give me the names of two or three sorts well adapted for all seasons. We find Paterson's Victoria very good, but substituted Climax for it last year.—J. D. H.

Early Peas for Transplanting.—Ever since the plan of sowing early Peas under glass for transplanting to the open ground has been practised the use of strips of turf for the purpose has been known and advocated. The plan has some obvious advantages over pans, pots, or even boxes of a certain character, but its weak feature consists in the fact that either the turf must be placed on some hard substance, into which the young roots cannot enter, and thus promote weakness and degeneracy, or, if placed on some soft material, such as soil or manure, the young roots soon penetrate it freely, and the disturbance caused to these when transplanted is productive of much mischief. There is yet another danger when strips of turf are used; the turf may contain wireworm or other dangerous insects, and roots of the young plants might be eaten. If the plants be turned out of pots, pans, or ordinary boxes, then the young roots must be seriously disturbed, and we all know that when plants are so moved from under glass to the open ground, say in the month of March, that it takes some time to get them established and ready to take advantage of the shift to make the required progress. One plan that I have known from experience to answer famously is having a lot of narrow boxes of, say, 2 ft. in length, 4 in. deep, 2½ in. wide on the top, and 3 in. wide at the bottom, inside measure; these are made with movable bottoms, kept in their place by means of hooks and eyes, two on either side; these are filled with soil, the Peas sown, and then placed together in a frame, where they can remain until the plants are 4 in. in height and ready for transplanting. When this is done deep drills are drawn, the boxes are inverted, the bottoms taken off, and the frame containing the Pea plants placed lengthways in the drill; owing to the shape of the box it will lift freely from the plants without disturbing the roots, and these are found to have formed a mass ready at once to take hold of the new soil. Twenty of these boxes may be made in a short time, and to secure the correct form it is but necessary to cut the ends of the right size—2½ in. by 3 in.—and all the rest will follow. These boxes might be used with advantage in the autumn for striking cuttings of bedding plants.—A. D.

Potatoes during Frost.—In large vaults Potatoes are exposed to but a minimum of danger; it is when they are stored in ordinary sheds, fruit-rooms, stables, and similar places that danger is to be apprehended, and where all possible precautions are necessary. Where there is a bulk of one sort the safest place for it is on the floor, and it should be kept in bounds by means of stout boards. For this the covering should in the first place be cloths, sacks, or any close-lying and air-excluding material, and upon this a thick covering of straw, the thickest portion being upon the crown of the heap, where a little moisture is likely to accumulate. If the bulk be dry, it is a great point in favour of the safety of the tubers. Smaller quantities may be well secured in bins, boxes, or tubs, but hampers should be avoided, and if some be stored on shelves, it is necessary to be as particular as to the nature of the floor on which they lie, as upon the thickness of the covering. If in boxes or tubs, these should be placed close together, and should have some sacks or similar covering over them, and then a thick covering of straw. In all cases it is well to put some boards, slabs, or anything at hand upon the straw to make it lie close, and thus exclude as much air as possible. When a thaw takes place, three or four days at least should elapse ere the covering is removed, as should any little touch of frost have got admission, it will be productive of less damage if it be allowed to escape gradually.—A. D.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 11.

On this occasion the Fruit and Floral Committees met in the large conservatory, as the annual general meeting, which took place on the same day, was being held in the council-room.

First-class Certificates were awarded as follows—

Rubus roseiflorus (Green).—A Bramble with large, double, white flowers, well adapted for pot culture. The plants from which the blooms shown were cut had been in flower ever since December last.

Cypophentia macrocarpa (Bull).—A graceful Palm with arching, feather-shaped leaves of a brilliant bronze colour when in a young state, changing to shining green.

Medals.

A small gold Banksian was awarded to Mr. Bull for a collection of new and rare plants, Orchids, &c.

A silver Banksian to Mr. B. S. Williams for a group of Orchids, Amaryllis, Primulas, &c.

Silver Floras to Messrs. Veitch & Sons and Messrs. Osborn & Sons for collections of forced plants, &c.

Miscellaneous Subjects.—Messrs. Veitch showed an attractive group of plants, consisting of finely-flowered little bushes of *Lilac* Charles X., *Rhododendron caucasicum*, Ghent *Azaleas*, &c.; these were backed up by graceful Palms and edged with a bank of *Cyclamen* and well-flowered clumps of *Lily of the Valley*, *Vermilion Brilliant* and *Tournesol Tulips*. A panful of finely-flowered plants of *Staphylea colchica* attracted much attention. Mr. B. S. Williams contributed a group of Orchids and a large collection of plants of *Primula sinensis* fimbriata coccinea and its white variety, the flowers of which are fine in form and larger in size probably than those of any *Primula* which has been before exhibited, and they are fine in colour. Among the Orchids were *Dendrobium Wardianum*, a plant of *Cologyne cristata* bearing upwards of 200 flowers, *Sophranitis grandiflora*, *Odontoglossum Rose majus*, and others; also several seedling *Amaryllis* of a meritorious character. The same exhibitor also furnished a new Fern named *Asplenium Novæ-Caledoniæ*, the pinnae of which are of a bronze-green colour; it is well adapted either for pots or pans. Mr. W. Bull contributed some choice plants, among which were noticeable *Sarracenia Drummondii* alba, *Dendrobium Fitchianum*, and *Eucharis candida*; also finely-flowered examples of *Onidium macranthum hastiferum*, *Leelia anceps*, *Odontoglossum cucullatum*, and *O. gloriosum*. Associated with these were well-grown plants of the narrow-leaved *Dracaena viviana* and *D. triumphans*; also *D. Goldiana*, choice Palms and Cycads, and finely-grown plants of *Cureligno recurva variegata*. Mr. Wills, of South Kensington, showed an attractive group of plants, consisting of stalwart Palms, fine-leaved *Dracaenas*, and Indian *Azaleas*, overtopping a thicket consisting of the snowy white *Cologyne cristata*, *Odontoglossum Alexandre*, *Lily of the Valley*, &c., interspersed with Maiden-hair Ferns and Club Mosses. Mr. Farr, Harrow Weald Park, sent cut blooms of *Poinsettia*, remarkable specimens of good culture, being very large and of the most brilliant colours; a vote of thanks was awarded for them. The same exhibitor also contributed cut sprays of *Begonia glaucifolia*, which is grown successfully at Harrow Weald in baskets. Mr. George, Putney Heath, furnished blooms of *Abutilons* to show their value in a cut state in winter. A fine collection of flowers of seedling *Abutilons* was also contributed by Mr. Farr. A plant of *Abutilon igneum* was shown by Mr. B. S. Williams. A large collection of Chinese *Primroses* was exhibited from the Society's gardens at Chiswick; they were well varied, both in colour and habit, and some of the old as well as modern strains were represented. Finely-grown examples of the old double *Primula* were also shown. Mr. Green, gardener to Sir G. Macleay, Ranelagh Court, exhibited blooms of *Sparmannia africana* and *Dahlia Maximiliana*. Mr. Cannell, Swanley, was awarded a vote of thanks for a stand of cut blooms of zonal *Pelargoniums*, all unusually bright in colour. Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, showed fine varieties of *Philæx*, *Sisya grandiflora*, and *Odontoglossum Rose majus*. Messrs. Veitch contributed a hybrid *Dendrobium* named *Endocochilus*, the result of a cross between *D. japonicum* and *D. heterocarpum*; also a flesh-coloured Chinese *Primula* named *Peach-blossom*. Mr. Bunchar, Wilton House, Southampton, contributed a plant of *Onidium superbiens* bearing a long twining flower spike beset with rich chocolate-coloured blossoms.

Fruit.—Mr. Haycock, gardener to R. Leigh, Esq., Barham Court, Maidstone, contributed a magnificent collection of Apples and Pears which attracted much attention. Among Apples were especially noticeable handsome, plump, and well-coloured examples of *Reinette du Canada*, *Melou Apple*, *Forge Apple*, *Reinette de Caux*, *Belle Dubois*, *Cox's Pomona*, *Beauty of Kent*, *Lincoln Pippin*, *Lord Burgley*, *White Calville*, and *Gooseberry Pippin*. Of Pears the best were *Passe Crassane*, *Broompark*, *Josephine de Malines*, and *Duchess de Bordeaux*. A good collection of Apples also came from Mr. Rivers, Sawbridgeworth, among which were *Annie Elizabeth*, *Winter Hawthornden*, *Norfolk Bearer*, and *Norman Greeng*.

Anniversary Meeting.—This was held on Tuesday last at South Kensington, Lord Abercrombie in the chair. The report of the Council was unanimously adopted. The agreement between the Royal Commissioners and the society for the occupation of the South Kensington Gardens terminated at Christmas last. By this agreement the Commissioners waived

re-entry till 1893, provided the society could, between 1875 and 1878, raise its annual income from subscriptions to £10,000. The efforts to fulfil this condition have failed. No intimation has yet been received from the Commissioners that any substantial alteration in the occupation of the gardens is at present intended, and the Council hope arrangements may be made by which the connexion of the society with the gardens, in all those respects in which it has been beneficial to the best interests of the society, may be maintained. The Council is convinced that the Commissioners, in the discharge of their trust as managers of the estate, will adopt no measure without giving the utmost consideration to the fair claims of the society and its position as a scientific association.

ANSWERS TO CORRESPONDENTS.

Peach-house Pathways.—"Welshman" (p. 132) will find a wooden trellis pathway the most useful and also cheapest. The trellis should be made in lengths not longer than 6 ft., as they are then easily movable for the purpose of cleaning, top-dressing the border, &c.; watering, of course, can be done without removal. The recommendation of the above kind of pathway is on the supposition that the entire floor of the house is required or intended for the border. If, however, there is room for the border apart from encroaching on the intended pathway, then either paving tiles or York flag-stones would make the most lasting and neatest floor.—W. W. H.

—If "Welshman's" Peach roots are in an inside border, the best pathway he can have is a trellis one, as that is always comfortable and dry to walk upon, and does not prevent light and air from reaching the soil, which anything in the way of flooring tiles or cement would do, and, unless rounded, with due provision made for draining off the water, would often be sloppy and unpleasant; besides which, there is the labour and trouble of scrubbing and keeping such a length clean, whereas with a trellis the traffic and an occasional sprinkle with the watering-pot remove what dirt or deposit there may be on it. Strips of Elm about 2½ in. wide and 1 in. thick nailed on to Oak cross-pieces are the most lasting, but good deal with just the sharp edges taken off, wears very well and is lighter; if tarred on the under side, and painted with two coats of lead-coloured paint on the top, its appearance will be improved and the wood will be rendered more durable by keeping the wet out. In making the trellis, which should be from 2 ft. to 2½ ft. wide, the strips of wood should not be nailed more than 1 in. or so apart.—S. D.

Chinese Primulas.—My Primulas are damping off at the base of the stem. They were particularly fine plants, strong and healthy, and were watered most carefully. On examining those affected I find quantities of minute white insects in the decayed part as well as under the earth. I have used lime and sulphur, but with little effect.—K. T. [To the insects to which you allude must not doubt be attributed the cause of the plants dying off. They are not unfrequently found at the roots of Primulas and other plants, and are doubtless brought in with the soil. The only remedy, or rather preventive is to use soil in which you are satisfied they do not exist. There is little chance, we fear, of saving your plants this season.—S.]

Early Peaches and Nectarines.—Is it necessary to artificially fertilise these in order to secure a crop?—W. J. [All that is absolutely necessary is to admit plenty of air both at top and bottom of the house on all favourable occasions, and to give the trees or trellis a sharp tap now and then when the blossoms are fully expanded, especially during sunshine.—S.]

Names of Plants.—F. W. H.—Your Heath is *Erica hymalis*; it should be cut down next month below the bottom flowers, and the side shoots should be stopped. Keep the plants of it a little close until the eyes begin to swell, then repot.—G.

Questions.

Orange Trees.—I have a favorite Orange tree in my small greenhouse about fourteen years' old in a 10-in. pot. It drops its leaves sadly, leaving only the stems of the leaves on the branches; and yet it is showing its buds for bloom. What can I do to get it into a healthy state? I do not see any scale or blight upon it.—WREDDEN.

Malformed Orange.—I send you an Orange with a piece of rind growing inside, beginning from the centre of the fruit, and extending nearly to the outer rind, forming the side covering of one of the segments into which an Orange may be divided. It is in appearance exactly like the outer rind, both in colour and substance, except that it is a little smoother and finer, but the difference is so slight as only to appear on close examination, and is not more than would be accounted for by the circumstance of its being protected from all exposure. You will see that there is a segment taken from the opposite side to that in which this malformation is found, otherwise the Orange is perfect. I shall be glad to learn if, amongst your correspondents, any one has observed a similar growth either in the Orange or any other fruit.—T. BAKER, *Weston-super-Mare*.

Broken Mercury in Thermometers.—I received a self-registering mercurial thermometer, maximum and minimum, a few days ago and found the mercury disarranged; it seems to be in little pieces. What shall I do to put it right?—SUBSCRIBER.

Perpetual or Tree Carnations.—Will Mr. Douglas or some other good Carnation grower kindly name six really good, free-flowering Perpetual Carnations to grow for furnishing cut blooms in winter?—P. S.

No. 379]

SATURDAY, FEBRUARY 22, 1879.

Vol. XV

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE TEA-SCENTED ROSE.

(Continued from page 114.)

Then will I raise aloft the milk-white Rose,
With whose sweet scent the air shall be perfumed.
Shakespeare.

LOUISE DE SAVOIE is one of the most robust of the Tea-scented Roses, but, like the article which is sometimes "recommended as a good, useful Family Tea," is not of *la première qualité*, and not many of its large and abundant flowers have the symmetrical outline which Rosarians love. No defects, however, can justify the insolent audacity of the young man who said, "that Louise was not a Tea Rose at all," and, when called upon to explain, replied, with a sinister drooping of the eye, commonly called a wink, "that if she was a *Savoy* she must be a *Cabbage*." The police are on his track, and there is a confident hope that he will be brought before the Tribunal of the National Rose Society very early in April next. Ma Capucine (the title perplexes me, for who would address a Capuchin nun or a Capuchin Caper, i.e., a *Nasturtium*, with such a term of endearment? and "ma" must, therefore, I think, be a misprint for *la*), is a seedling from Ophiré, and a most striking Rose as to colour. Her complexion is described by an eminent Rosarian as "coppery-red," but as this may be associated in some minds with hot coppers and alcoholic excess, I will suggest instead that combination of scarlet and gold, red and yellow, which we see in the *Tropæolum*, and which gives the name to the Rose. It is lovely in its buds, and as appropriate for the button-hole of the "best man" at a wedding as Madame Bravy, the next Rose of my selection, for the bouquet of the bride. Perfect in her own style of beauty is Madame Bravy, of exquisite shape, every petal of which is as regularly disposed as those of a white *Camellia*, but with a more pleasing, because less formal, grace; and in colour *Alba-Rosea* (by which terms, and no other, the Rose has been known to some Rosarians), that is, white and red, white, pure white, yet blushing in her modesty, like the bride who holds her in her hand. Madame Camille is a recent and welcome addition, in colour pink and white, in shape (as described in a French catalogue) *forme de coupe*, and what could be more appropriate for a *Tea*? Madame Falcot has a wide dominion over the hearts of men; however intently those hearts may be absorbed by business or by pleasure, above all she sits supreme. On the rail, in the club, in the counting-house, married or unmarried, they carry with them the image of Madame Falcot. I have seen her riding in the Park with the statesman and the general, the old and the young, the wise and the foolish, and invariably dispensing with a second horse, mounted, not as our foremothers, on a pillion behind, but secured in front—by a pin to the coat! I need hardly add that, having a complexion of "rich apricot-yellow," she evokes no jealousy. On the contrary; I was informed that only last season she was pronounced by one of the belles of the park aforesaid to be "a too awful sweetie," and when, hardly understanding the delightful diction of the day, I asked my informant kindly to translate it, I was contemptuously told that "of course, it meant a regular stunner and all that sort of thing." Madame François Janin is another of those small darlings, *Mignonettes* (and, in this instance, the Rose is as fragrant as the flower which specially bears that name) irresistible as we see it, with its bits of *Adiantum*, in the windows of the floral purveyors, and yet more winsome, as a matter of course amid its own leaves on the tree. This Rose gives a most ample harvest of its bright orange flowers under glass, but I must add that I have not yet seen it in its happiest phase out-of-doors. Mr. William Paul, in the last issue of his "Rose Annual," give us the chromo-lithograph, from a picture

by Mr. Fitch, of a most lovely Tea-scented Rose, Madame Lambard, which has flowered with him beautifully under glass, and, according to the portrait and description, must be the Rose of its season. The petals, which are ample and well-formed, are of a bright primrose-yellow, deeply edged with a soft rose. Mr. Geo. Paul tells us that Madame Lambard is "of very fine and splendid China-like habit," and we have, therefore, every ground for hoping that we shall soon realise in our gardens the manifold charms which in this country have so far been seen only under glass. Madame Margottin well deserves a name, beloved by those Rosarians, to whom "old Jules" has been a dear and faithful friend for so many happy years. The pale yellow petals change into roseate tints in the centre of a large, and globular, and very attractive flower. Were we to serenade Madame Mélanie Villermoz, our song must surely be—

We have lived and loved together
Through many a changing year.

She seems to be acclimated to the severities of our English seasons, and, before the seedling Brier was in use, was one of the few of the Tea-scented family which rarely disappointed our confidence. In its best form it is a large and very handsome Rose, with the white outer petals deepening towards the centre into red, a good traveller, and, therefore, a reliable Rose for the show. Marie Sisley is a most charming contrast to her sister Aline (previously noticed), both daughters of Guillot, and born at Lyons. Like Minna and Brenda in "the Pirate," the one is a blonde, the other a brunette. Aline a dark rose, and Marie a pale yellow, *largement bordé de rose vif* (as described by Papa Guillot), distinctly edged with bright rose.—The artist, who painted the clever likeness of Marie Van Houtte (Plate CLXI. p. 80), was unkindly dealt with by the florist who supplied the Rose. The painter, in fact, was placed in the unpleasant position of the man, who is represented, in an impossible drama, as having run away in the dark with the mother instead of the daughter. The Rose, so accurately drawn and coloured, is past her prime. I do not say that she is not still beautiful; many fair women never lose their beauty, and I have before me, as I write, a picture of my grandmother, which all admire who see—but had the portrait been taken two days earlier, the readers of THE GARDEN would have gazed on a far more lovely Rose. For, indeed, she is, in her perfection, like the missing Flora, as described by her swain to the shepherds, "in form and feature beauty's queen," whereas in the picture the shape has lost its symmetry, and collapsed into a condition designated by an old Yorkshire gardener as "fothery;" and the pure tints of primrose bordered with rose have, I cannot say disappeared, but have lost much of the beauty which they possess from their arrangement before the Rose passes from its most perfect form.

When the first grand *Fête des Roses* of the season was held last summer in the Crystal Palace by the National Rose Society, a small company of skilled Rosarians was anxiously but happily engaged in closely inspecting and earnestly discussing the merits of an unknown Rose. Each visitor was invited on arrival by the owner, Mr. Arthur Soames (a gallant young officer in the Wars of the Roses, who will one day be a *Maréchal Vaillant*), to scrutinise and then to name this Rose. Each at first looked amazingly wise and confident, with an expression which seemed to say, "Enquire within for everything;" but this aspect of sagacity gradually changed first to doubt, and then to despair: "'tis this, and 'tis that, we cannot tell what." In two conclusions we were unanimous—that the flower before us was a gem of purest ray serene, one of the most perfect Roses of the show, and that not one of us had seen it before. Mr. Soames was not himself certain as to the name (the tally having been lost, if I remember right), but he believed it to be *Monsieur Fortado*, and from the description given in the catalogues, French and English, I fully concur in that belief. In the former it is justly announced as *fleur grande, très pleine, superbe*, and in the latter "fine, bright, sulphur-yellow, large, full, and good form, an improved *Narcisse*." The plant is of delicate habit, but this is often the case with new Roses, weakened by a too rapid multiplication; and we must endeavour, by a careful and patient culture, to realise the wonderful capabilities which we know belong to this illustrious stranger. Some of the buds, which Mr. Soames kindly

sent to me, have so far outlived the severities of this abnormal winter, and the Rose which he showed us in June last, will ensure for these little Furtados all the vigilance of a Rosarian's love.

There is one Rose—only one, good gentlemen—which I do not appreciate, do not admire, as (I suppose) I ought. Seriously, it is a sad confession to make, because no one sympathises with me, and, being a gregarious animal, I don't like isolation; I feel like one who treads alone some Floral Hall deserted. Though I do not believe in *Vox populi, vox Dei*, because poor human nature is swayed more, as a rule, by passion than by principle, I know that it is not good for man to be alone, even in his estimation of a Rose. I am aware that Niphetos (the pronunciation is Niffytos, not, as some utter it, Ni-fee-tos, because the e in the Greek word, from which the Rose is named, and which signifies a snow shower, is epsilon and not eta, not long but short), I am aware that Niphetos is the Rose *par excellence* for the London market, that its buds are grown by the thousand for button-holes and bouquets, and I can see that in its babyhood the Rose is beautiful, but in its maturity, though again and again I have shown it in victorious "stands," seen it pointed at, and heard it praised, as one of the most effective flowers in the box, yet can I never regard it with that tender devotion and admiring love with which I gaze on Catherine Mermet, Marie Beauman, or La France. There seems to me no life, no character, no sentiment about Niphetos. It resembles one of those imitations of the Rose which are so exactly correct in their formation and colouring, and yet want the freshness, the spirit, of the reality; or rather, I would say, that while in these artificial semblances there is always something defective, it would be possible, in my opinion, for a clever artist to reproduce in white paper a *fac-simile* of Niphetos which would deceive the connoisseur and defy the critic. More I dare not say. It may be, indeed, that in this matter I am the dupe of some optical infirmity, some prejudice which I cannot overcome, but, in speaking of Roses, all that is in my heart must be spoken, even though my candour should imperil that sympathy of my brethren, which I dearly prize. *Perle des Jardins*, in a fine hot summer, grows and blooms abundantly, and its yellow Roses, deepening in the colour of their central petals, are often very beautiful; but with me it is as a voyager who, merry and loud while the calm continues, is among the first to collapse when seas are rough; or like one of those fine-weather Christians who come to church in their new hats and bonnets only when the sun shall shine.—*Perle de Lyon*, though its title is not so pretensions, is a more desirable Rose, of an exquisite form, well delineated in the engraving given by Messrs. Sonpert & Notting in their *Catalogue Général* for 1878-9, and having large, deep yellow flowers.—Rubens would have rejoiced in the Rose which bears his name. Though in many points different and distinct from *Devonensis*, it bears a general resemblance to that glorious flower, and I have grown it on a wall with a south aspect as large and as lovely. Here is the truthful description given by one who has long had signal success in the culture and exhibition of Tea Roses, Mr. Cant, of Colchester (and all of us like Canton Teas): "white, delicately tinted with rose, large and very beautiful, first-rate form, a superb variety." Rubens, nevertheless, is surpassed, as a rule, by *Souvenir d'Elise Vardon*, and Mr. Cant adds the words "splendid" and "magnificent" to a description in other respects very similar.—The penultimate o seems to suppress the idea of relationship between Miss Eliza Vardon and Miss Dolly Vardon (though members of the same family do not always spell their names alike, e. g., the Smiths and the Smythes, the Taylors and Tayleures, &c.); but, be this as it may, they are alike charming in their different styles of beauty, and I am quite sure that Dolly (of whom we had a souvenir no long time since in a revival by our damsels of her quaint kirtle) that Dolly, "all smiles, and dimples, and pleasant looks," was never more admired by Mr. Simon Tappertit, handsome Joe Willet, or "the fifty or sixty young fellows who were breaking their hearts to marry her, and for whom she cared no more than if so many oysters had been crossed in love and opened afterwards," than our Belle Elise by her fond adorners wherever she deigns to smile.

S. REYNOLDS HOLE.

(To be continued.)

CULTURE OF OUTDOOR PLANTS FOR MARKET.

SWEET PEAS.—These are grown in considerable quantities near London for the sake of their blooms—a white and a scarlet-flowered kind being favourites on account of their decided colours. The seed is usually sown along the sides of walks and similar places in October and November, when our early culinary Peas are sown. When the plants appear above ground, a little earth is drawn up to them, and early in spring they are staked, which in a measure protects them from cold winds and frosts. If the weather be favourable, plants from these sowings come into bearing early in May, and afford a good supply of blooms until the end of July. The earlier Sweet Peas can be got into bloom the more valuable they are for market purposes, and the more regularly the blooms are kept cut the longer the plants continue to grow and flower. Successional crops are obtained from sowings made in spring, but the summer and autumn crops are, on account of the drought, very often but short-lived. A good, heavily-manured piece of ground is in all cases chosen for them, and this in as moist a situation as can be secured. All expanded flowers are cut three times a week, tied in bunches as large as one can hold in the hand, packed in baskets, and taken to market. As in the case of Wall-flowers and Daffodils, the retail dealers who purchase them untie the bundles and, after selecting the best blooms for bouquet making—for which purpose they are admirably adapted—tie them into smaller bunches, and sell them for 1d. or 2d. each. A good plantation of Sweet Peas in favourable seasons is highly remunerative; but in very dry weather little profit is realised by their culture. A portion is also left untouched for seeding purposes. When the pods become brown in the autumn the plants are pulled up, tied in bundles, and housed until a convenient time has arrived for threshing out the seeds.

EVERLASTING PEAS.—These are not grown to any great extent—a circumstance to be wondered at, as there are many kinds which would yield plenty of bloom, and of a good colour. *Lathyrus latifolius* and its white variety, *L. Sieboldi*, and also the red-flowered *L. Drummondii*, for example, one would think, might be grown against walls or in any corner where good soil could be procured. Their blooms are, however, not so sweetly scented as those of the Sweet Pea.

VIOLETS.—During the autumn and spring months any one visiting Covent Garden Market, or its neighbourhood, must have seen piles of Violets exposed for sale. They are tied up in small bunches, each surrounded by a few green leaves of their own, and sold for 1d. each, or more, according to the time of year and the quantity in the market. At Twickenham, Strawberry Hill, Richmond, Teddington, and other places on the side of the Thames, Violets are grown to a considerable extent. They are usually found under orchard trees—a position in which they thrive remarkably well—and I have often seen dozens of women gathering the produce and placing the bunches, after being tied up, in square hampers, ready for men to carry on their heads to the nearest railway station to be sent to market. The following extract respecting Violet culture is taken from "The Gardener" for the month of September, 1877:

"A position sheltered from the north and west, and sloping towards the south, is chosen for the plants, as, under such conditions, they flower better at the close of the autumn, and also in winter than they otherwise would do—seasons when the flowers bring the highest prices. Before planting, the soil is well stirred up with the spade,

and, although the roots of the Violet do not descend very deep, the plants grow so much the better and more vigorously in proportion to the depth of soil. The large lumps or clods are well broken and pulverised with a long-toothed iron rake or a fork. Lines or drills are then marked out, at a distance of 1 ft. from each other, and the plants are set at about the same distance from each other in the rows. Every four rows form a bed, so that the flowers of two rows may be gathered from the alley on each side without trampling on the soil of the bed or on the plants themselves. The plants are chosen from the strongest runners, which the largest plants produce in quantities, like the Strawberry. The most favourable season for planting is in March or April, the plants being usually inserted in the rows with a dibber. The kind of manure employed, especially in cold soils, is street-scrappings, and is the manure almost exclusively used by Violet growers and Strawberry growers in the neighbourhood of Paris. The third year after planting, the flowers become less abundant, are smaller in size, and grow on shorter stalks. After the third year the plants are pulled up, and fresh plantations are made. A few growers adopt frame-culture during the winter and early spring months, the frames being surrounded with warm manure or leaves for the purpose of keeping out the frost. When treated in this way the plants will afford a succession of flowers up to February. Taken altogether, the profit on each frame used in forcing Violets in this way amounts to from 10s. to 20s. Violets are also forced in heat, either on a hot-bed or with the assistance of hot-water pipes, and sometimes both are employed together. This method is generally resorted to when a good supply of flowers is desired about New Year's day.

It is difficult to calculate accurately the probable produce of a crop of Violets, as it is exceedingly variable. In one season 12,000 bouquets may be gathered from $2\frac{1}{2}$ acres of ground, while in another season the same ground may not yield more than 3000 bouquets. But usually the profit is greater when the general crop is moderate, as, when the crop is abundant, prices fall very low in the market, and sometimes hardly do more than repay the various expenses of culture, rent of ground, &c. This will be made plain from the following calculations on the produce of $2\frac{1}{2}$ acres during three seasons of maximum, medium, and minimum produce. In a year of plenty (say 12,000 bouquets to $2\frac{1}{2}$ acres), the first bouquets of winter and the latest in autumn will fetch about 5d. apiece, and when the full crop comes in in spring, 1d. apiece. Supposing one-half the crop sells at the first price, and the other half at the second, we have 12,000 bouquets at 3d. each = £150. Against this we must set off the expenses as follows:

Rent of $2\frac{1}{2}$ acres of ground	£12 0 0
Digging and preparing the soil	4 8 0
Three hoeings at £2 8s. 4d. each	7 5 0
Manure	14 8 4
Planting	2 10 0
Spreading the manure	1 5 2
Cutting off the runners	0 16 8
Gathering, packing, and other market expenses of 12,000 bouquets at 1d. each	50 0 0
Total	£92 5 2
Deducting this from	£150 0 0
	92 5 2
We have a profit of	£57 14 10

If, now, we take a season with a medium crop (say 6000 bouquets to $2\frac{1}{2}$ acres), these will sell for 2d. each at the lowest price, and for 10d. each at the highest, or 3000 at 2d. each, and 3000 at 10d. each = £150. The expenses will be the same as in the last case, except for the gather-

ing, packing, and other market expenses, which, for 6000 bouquets at 1d. each, will be £25, instead of £50. Deducting this from £92 5s. 2d., we have £67 5s. 2d., which, deducted from £150, the market value of 6000 bouquets, leaves a profit of £82 14s. 10d. Lastly, let us take a season with a minimum crop of, say, about 3000 bouquets to $2\frac{1}{2}$ acres, of which 1500 will fetch 1s. 0 $\frac{1}{2}$ d. each (or £78 2s. 6d.), and 1500 will sell for 4d. each (or £25), equal in the total to £103 2s. 6d. The general expenses will be still the same, except in the matter of gathering, packing, &c., which for 3000 bouquets at 1d. each, will amount to £12 10s. To this must be added the other expenses, which, as before, amount to £42 5s. 2d., making a total of £54 15s. 2d. Deducting this from £103 2s. 6d. (the market value of the 3000 bouquets), we have a profit of £48 7s. 4d. From the foregoing calculations it will be seen that the profit is greatest in seasons of medium produce, since, in years of maximum yield, the various expenses of gathering, packing, &c., are much increased, while the market price is diminished to the lowest—indeed, sometimes so much that growers do not care to gather their flowers. On the other hand, in seasons of minimum produce, it is the other general expenses, which, remaining, as they do, unchanged, swallow up the greater part of the profits. It must be understood, however, that the figures given here are only approximate."

Those who purchase or are presented with bouquets of Violets have, as a rule, little idea of the labour required to produce them and prepare them for market. Violets are cultivated on a large scale around London, and in some parts of Kent, Surrey, Middlesex, and Sussex Violet culture is a most lucrative industry.

LAVENDER.—Under some conditions this is, perhaps, a more profitable crop than either vegetables or fruits, and few people are aware of the immense quantities of it which are grown within 20 miles or so of London. In Surrey alone there is supposed to be no fewer than 350 acres of land devoted to its culture, and almost as large a space may be found under Lavender in Hertfordshire. At Mitcham both cottagers and market gardeners grow Lavender for sale, and when the fields of it are in bloom its fragrance pervades the air for miles. Lavender is increased by means of rooted slips, obtained by division of the old roots. The young plants are put out in March or April, 18 in. apart, in rows half that distance asunder, the space between the rows being the first year planted with Lettuce, Parsley, or some similar crop. When the Lavender becomes crowded, each alternate row and plant are lifted and transplanted to another field to form a new plantation. The remaining plants then stand 3 ft. apart each way, and intercropping is discontinued. During the first two or three weeks in August the flowers are harvested. The stalks are cut off with a sickle, bound up in sheaves similar to Wheat, and carried to the homestead for distillation or for other purposes. In Hertfordshire a somewhat different method is practised. The young plants are put out in November, 3 ft. apart each way, no other crop being grown between them, and the ground is well tilled and attended to. When three years old, the plants are considered at their best, and after they have been planted seven years they are dug up and the ground is replanted. A new plantation is, however, made every year or so, and thus there are always young, vigorous plants upon which dependence for a crop of flowers can be fully placed. It is estimated that there is on an average sufficient Lavender flowers grown in England to produce from 25,000 to 30,000 gallons of Lavender water, the greater part of

which is produced at Mitcham and Hitchin. Some market gardeners also grow Lavender in spare corners and between fruit trees. This is cut before the flowers are fully expanded and sent to market, where it is tied in small bundles, and hawked about the streets or sold on the stalls for 1d. or 2d. each. Where a stock of young, vigorous plants is kept up, good profits are often realised by the culture of Lavender for sale in this way.

CHRYSANTHEMUMS.—The blooms of the incurved Japanese section of Chrysanthemums during autumn, when Camellia blossoms are scarce, have a good run in the market, and fetch high prices. White blooms are most in demand, and at one time the Anemone-centred or quilled kinds were most thought of, but since such beautiful kinds belonging to the Japanese section have been raised they are less popular. The flowers of the Japanese varieties are much more graceful than any of the other kinds, and on that account everyone admires them. For sale in pots large-flowering Chrysanthemums are little grown, but the Pompon varieties are cultivated to a large extent for this purpose. Cuttings of these are struck in frames in June after the latter have been cleared of bedding plants. As soon as struck, the Chrysanthemums are transplanted to the open ground with a dibber, allowing plenty of space between them. The points of the shoots are picked out once or twice during the summer, and as soon as the plants show bloom they are lifted and potted into convenient-sized pots, well watered, kept in the shade for a time, and housed when sharp weather is apparent. The soil in which they are planted is sandy loam, light, but not very rich. The three forms of *Cedo Nulli*—golden, lilac, and white—are the principal kinds that are grown in pots. A section of early flowering Chrysanthemums, too, which has of late years been introduced is very eligible for market purposes. The plants assume a dwarf, compact habit, and the flowers, though not so large and perfect as the autumn-flowering kinds, are very effective, and, either in a cut state or on the plants, are valuable, especially as they come in in August. Some of the best kinds in the large-flowered section, with incurved petals, are: Alfred Salter, rosy-lilac; atro-rubens, dark red-carmine; Attraction, bluish; Beverley, ivory-white; Cherub, golden-amber; Christine, peach; Empress of India, pure white; Gloria Mundi, golden-yellow; Guernsey Nugget, primrose-yellow; Mount Edgecumbe, white, rose tinted; and, the best of all, Mrs. George Rundle, pure white, of fine form. Among the Japanese or ragged flowered kinds are: Jane Salter, white, tipped with rosy-lilac; Reine des Blanchés, white; Magnum Bonum, rosy-lilac; Boule de Neige, pure white; Elaine, white and carmine; Garnet, blood red; and James Salter, lilac.

MICHAELMAS DAISIES.—When flowers are scarce in the autumn, cut blooms of these may often be seen in the market, where they sell for the same price as those of Violets, viz., a penny a bunch. The varieties usually consist of the small-flowering kinds, which, when neatly arranged and surrounded with Violet leaves, are very pretty; and shoots of some kinds bear so many flowers as to form neat little bouquets of themselves. The plants are increased by means of cuttings, and also by division of the old roots when young plants are required for sale in pots; but when cut bloom only is needed the old plants are frequently allowed to remain in some out-of-the-way corner undisturbed for years. Of small-flowered kinds, the best for market are *Aster dumosus*, bluish; *ericoides*, white with yellow centre; *horizontalis*, white,

rosy-lilac centre; *multiflorus*, white, neat and pretty; and *Shorti*, lavender-blue. Among the large-flowered and attractive kinds which bloom in autumn are: *Amellus*, lilac-blue; *casiarubicus*, blue, orange centre; *grandiflorus*, purple; *linarifolius*, purplish-lilac, light centre; and *Novæ-Angliæ*, rich, shining rose, with an orange centre.

DAHLIAS.—Many of the dwarf varieties of these may often be seen offered for sale in pots in the flower market. They are struck from cuttings inserted in the spring, and planted out-of-doors in rich soil as soon as the weather is sufficiently mild for them. As soon as the flowers begin to expand, the plants are lifted and put into 6-in. and 8-in. pots, well watered, and brought to market, where they find a ready sale for the ornamentation of windows and balconies, positions in which, if shaded and kept well supplied with water, they continue in good flowering condition for a long time. The flowers of both the large-flowering and the Pompon varieties are also largely used in autumn in the commoner kinds of bouquets, along with Roses, Pelargoniums, and other flowers which are then plentiful, but their culture expressly for market is not great. They are increased by division of the old tubers, or by taking up the same and introducing them into heat in spring; when they throw up young shoots, those which are not pithy are taken off with a heel and inserted in small pots in a gentle bottom-heat. When well-rooted, they are hardened off, and in June are planted out-of-doors. The majority of the blooms which come to market are, however, obtained from plants left in the ground for years, the roots of which are protected in winter by a covering of ashes or loose litter. Late in autumn the flowers are most valuable, especially the white ones of the Pompon class, and if they are protected from autumn frosts they sometimes fetch good prices.

To these may be added Canterbury Bells, Delphiniums of the formosum type, Anemones, and Eschscholtzias, the blooms of which are largely used in the commoner kinds of bouquets, but none of which are sold in pots. Roots of them, as I have before stated, are disposed of by thousands outside the market. The blooms of the blue Cornflower (*Centaurea Cyanus*) are largely used in bouquets in spring and summer. It is a native plant, and grows wild in abundance in many parts of England. Any one growing a stock of it, and allowing the flowers to go to seed, has no difficulty in getting plants of it, and, as regards blue flowers in Covent Garden, this and *Stokesia cyanea*, to which allusion has already been made, are the chief, not forgetting Blue Cinerarias and Violets.

C. W. S.

A Reminiscence of The Tulip Mania.—At the end of last December, says the "Deutsche Gärtner-Zeitung," two houses in the main street of Hoorn, about twenty miles from Amsterdam, were offered for sale for demolition. These houses were purchased during the Tulip trade which flourished from 1634 to 1637 with the proceeds of three Tulip bulbs! The record of this remarkable purchase was preserved in a stone inserted in the gable of one of the houses.

A New Darlingtonia.—This, which was found on Black Hawk Creek, in Sierra county, is represented in colours in the "Californian Horticulturist" for January. It presents a marked variation from plants of that family heretofore described. The "Scientific Press" some little time ago, represented the flower as about 12 in. high at maturity; in the patch of Darlingtonias from which the specimen in the "Horticulturist" was taken the flowers reach an average height of 40 in. Newberry's report on the Darlingtonia, in Prof. Bolander's library, represents the bracts upon the scape as increasing in number and size near the blossom, and finally blending with the floral envelope. With this the illustration given in the "American Agriculturist" agrees. A writer in the paper just mentioned examined hundreds of scapes, and found each without a vestige of a bract nearer than $\frac{3}{4}$ in. from the flower.

THE FLOWER GARDEN.

A QUIET NOOK.

The accompanying little drawing represents a scene at the bottom of one of the curious narrow vales in Somersetshire, in which grow many wild flowers that are not found in the open fields. It represents a colony of Solomon's Seal and Paris quadrifolia clustering over and around an old stump, and happy under the shade of the Hazel trees and beside the little stream that winds through the valley. It was drawn from Nature by Mr. Alfred Parsons, engraved by Mr. Hyde, and is one of the cuts prepared for a forthcoming edition of the "Wild Garden." It need not be said that numbers of hardy exotic

Solomon's Seal and Paris quadrifolia at home.

plants and ferns would thrive better in such places than in our trim borders, and would, moreover, thrive without care. W.

VIOLAS INTERMIXED WITH PELARGONIUMS.

VIOLAS, whether considered as such, or as Pansies, the two being still distinct, though blood relations, have, in my own memory, through patience, skill, and energy, made a development outstripping that of any flower with which I am acquainted, and, looking at that pretty weed of our arable land, the Viola tricolor, and those exhibition trays of large circular blooms of nearly every possible colour called Pansies, most of them seemingly cut out of Genoa velvet, there really appears something in selection and development. The Violas, so understood, are evidently nearly approaching the Pansies. Whilst the Pansy of the florist seems to have derived its excellence and perfection from itself, without aid from what we may call intermarriage, the Viola appears, as improved, to be the result of cross breeding or hybridising, and appears to be made up of the British Viola lutea, the Pyrenean V. cornuta, and the cultivated Pansy. The Viola cornuta made a stir on its first introduction into modern gardening, and its descendant, V. Perfection, is still one of the best bedding Violas known, retaining the colour of its parent (cornuta) with the size of a moderate Pansy, and what I intended, when commencing this article, was to point out a purpose for which it is peculiarly adapted, and that is, softening or toning down. A few plants of the above Viola, systematically planted with scarlet Pelargoniums, have a fine, cooling effect. Plants of it thus treated become somewhat drawn, so as to mingle their

blooms with those of the Pelargoniums, among which, owing to the size of bloom, it is very striking, yet soft and pleasing. Verbena venosa I have seen employed for the same purpose, but it is not to be compared for effect with the Viola. Among pink bedding Pelargoniums it is more beautiful still, owing to the nearer affinity in colour. The Viola will maintain the beauty of the bed when the blooms of the Pelargoniums are withered or wasting, and sparingly introduced among beds of white Pelargoniums (I am speaking of zonals) it is truly beautiful; here it may be said to give a warmth to the cold white of the Pelargoniums.

Ormskirck.

T. WILLIAMS.

ERYTHRINA CRISTA-GALLI, AS A BEDDING PLANT.

THIS, although a native of Brazil, is found to be sufficiently hardy to withstand (with the aid of some slight protection, such as that accorded to beds of Fuchsias) the rigour of an ordinary winter in this country. For many years it was supposed to require the temperature of a stove, and with liberal treatment it may be induced (when grown under glass) to flower satisfactorily twice during the season. It is subject, however, to the attacks of red spider when grown under glass, and on that account a somewhat close and moist atmosphere, and frequent syringings, are necessary to its proper development. It is, however, when planted out in a suitable soil and situation in the open air, that this plant, both as regards foliage and flowers, attains its greatest degree of perfection, and a good sized bed of it in the flower garden, associated with other plants, forms an attractive object; so much so, that it is to be regretted that it is not used for this purpose more frequently. It may be increased by means of seed, where that can be conveniently had, but it is generally grown from cuttings, which strike root readily, and in order to obtain them, a few old plants in pots should now (middle of February) be plunged in a brisk bottom heat, and these will soon furnish an abundant supply of cuttings, which should if possible be taken off with a heel, and inserted in a mixture of silver sand and finely sifted leaf soil, and placed under a hand-glass in the propagating pit. Here they will speedily strike root, and should afterwards be potted off singly when sufficiently rooted, and, under careful treatment, they will be large enough to plant out with other bedding plants about the end of May. They will bloom more or less freely during the first season, and if they can be preserved in the beds through the following winter, they will flower in greater perfection the second and succeeding summers.

The bed intended for Erythrinæ should be carefully drained, unless the subsoil is naturally of a light or gravelly character, as the plants during winter are more likely to suffer from damp or stagnant moisture than from severe frost, as the surface of the bed can readily be mulched with dry, littery matter, so as to effectually protect the roots of the plants from the effects of the latter. The bed should be composed of moderately rich, light soil, and the mulching should be removed soon after the middle of May, when the decayed stems should be cut off close to the surface of the soil, and a slight surface-dressing applied. As the young shoots progress, they will require to be neatly staked, more particularly if the bed be in an exposed situation. It is, of course, too early as yet to ascertain how such plants have fared during such a winter as that which we have just experienced, when the frost has penetrated to a much greater depth than is usually the case. But in a narrow border in front of a plant house, I saw, some years since, a line of these plants in full flower, and producing a grand effect. I was informed that they had withstood the exceptionally severe winter of 1860-61, and that they had never been protected in any way. It is, however, possible that in that case the roots of the plants derived benefit from their proximity to the front wall of a heated structure.

Culford, Bury St. Edmunds.

P. GRIEVE.

Stem Roots a Protection to Lily Bulbs.—As the writer in the "Californian Horticulturist" says (p. 118):—"We agree as regards the decay of the old bulbs and the formation of new ones internally," will Mr. T. Smith, of Newry, be good enough to say if

in "the interesting discovery he made a day or two ago" (p. 135), the bulbs he then found, which, as he tells us, "were perceptibly larger than when they were planted," were the same identical bulbs that were planted in "the beginning of April last year?"—B.

THE "FLOWERING" SPURGE.

(EUPHORBIA COROLLATA.)

THIS is one of the best of American plants, and in trade language it has "money in it," as it is one that may be grown by florists as a source of profit from the sale of its flowers. The genus *Euphorbia* is a large one, there being over 700 species which are widely distributed; those found in temperate climates are herbs, often small and inconspicuous, while in tropical countries they are shrubs and even small trees, some of which are very thorny and grotesque in habit. Without going into the details of structure, it may be said that the flowers are exceedingly simple, having neither calyx nor corolla; the male flowers consist of a single stamen with a small scale, and the female flowers of a single pistil upon a long stalk. Several of these simple staminate flowers and one pistillate flower are placed in a sort of cup or involucre, which hides the stamens, but the pistil, having a long stalk, stands out beyond the involucre. The latter, which passes for the flower, contains a whole cluster of very simple flowers. Though the flowers themselves are not showy, it is often the case that the parts surrounding them are very much so. One of the most brilliant plants of our hothouses is a *Euphorbia*, popularly known as *Poinsettia*, the leaves which surround the heads of involucre of this, are of the most intense scarlet colour. It is for these brilliant upper leaves—or bracts, as the botanist calls them—that large numbers of these plants are cultivated, as they are specially in demand for holiday decorations. In other greenhouse species, the involucre or flower-cup itself is showy, being furnished with large petal-like scarlet appendages or lobes, which make it very closely resemble a real flower. In our native Flowering Spurge (*Euphorbia corollata*) these appendages are of the purest white, and the plant appears as if it bore a cluster of small white flowers, while it is really a mass of very showy flower-cups, inside of which the real, but minute flowers are hidden, though in time the pistillate flower shows itself above it. This plant is found from New York westward and southward; it is abundant in the Pine-barrens of New Jersey, and in similar localities to Florida. It has a large branching, perennial root, which sends up several stems 2 ft. to 3 ft. or more high; the leaves upon the stem are scattered, without foot-stalks; at the top of the stem are several branches, and these branching again form the umbel-like flower cluster, at the base of which is a whorl of several leaves. As with other *Euphorbias*, all parts of this plant contain a milky juice which flows freely whenever a portion is cut or broken. The dried root has been more or less used in medicine, especially in the Southern States. The Flowering Spurge is an excellent border plant, as it produces abundance of—what in this sense we may call flowers—in July and August, and they last until October and November. The white petal-like lobes do not readily wither, and on this account the flowers are very useful for bouquets and floral decorations; small, white, lasting flowers are always in demand for such purposes, and the plant is likely to become popular among florists and those who grow flowers for cutting. While we have no doubt that the Flowering Spurge will prove a valuable plant to force for cut flowers in winter, we shall not recommend its use until we see the results of experiments now being made in this direction. We have mentioned that the pistillate flowers stand out beyond the involucre; as these are green and unsightly, they much detract from the appearance of the cluster, and they should be picked off when used for bouquets, &c. We are glad to see that this very handsome native plant is offered by dealers, though some of them make a mistake in claiming that it is new. That enthusiastic cultivator, the late Mr. Joseph Breck, in his "Book of Flowers," published a quarter of a century ago, and in his later "New Book of Flowers," speaks of it as a "most excellent species," while it was figured and commended as long ago as 1819 in "Loddige's Cabinet," and Duchate states that it was introduced into the French gardens in 1803. Nevertheless, a plant in the sense of being little known may be said to be new.—"American Agriculturist."

have always an abundance of flower in summer. Few plants are more showy in old-fashioned herbaceous borders than *Tigridias*.—CAMBRIAN.

THE FRUIT GARDEN.

TRANSPLANTING AND RENOVATING OLD VINES.

I NOTICED IN THE GARDEN a few weeks back some inquiries respecting the transplanting of old Vines, and as I have of late years been engaged every autumn in renovating borders, I am able to say that such work, if taken in hand at the proper time, may be carried out with the greatest success, and in most cases with marked benefit to the Vines. The reason for this is not so obvious at first sight, but when we take into consideration the immense increase clipping and severing some of the largest roots causes in the number of feeders, the gain at once makes itself apparent, especially when we bear in mind the large amount of fresh food there is supplied by the formation of new borders. Although the Vines I had to deal with were not actually lifted, they were to all intents and purposes the same as if they had been, as every particle of soil was harrowed out from among them, and every root laid bare under mats till new loam was put under them. From beginning to end this took a week, as working the earth out from among the roots was rather a slow process, but although this was the case, the leaves never flagged during the whole time, nor afterwards showed that they had been interfered with. Our success was due to the precaution we took to carry on the work during a dull time, when we could have the house entirely closed both day and night, and the foliage frequently syringed. Had the sun broken through, we were prepared with shades to run down the roof, and these we did use occasionally for a fortnight or more after the work was completed, for though the leaves were nearly ripe, we were anxious to preserve them fresh and keep them from falling as long as possible. This was done not only with a view to plump up and finish the buds, but to aid fresh root action before the winter set in, by doing which, the Vines started strongly the following spring and bore excellent crops. Those operated upon in one case were upwards of twenty years old, and had stems as large as one's arm, but for all that they already show symptoms of becoming regenerated and of being as vigorous as ever. Any one, therefore, who has Vines that from any cause do not give satisfaction, need not hesitate setting about their renovation, for there is no plant with which I am acquainted that is so tenacious of life or that will bear so many liberties being taken with it as the Vine. The best time to operate on old Vines is the last week in September or the first in October, as then the wood is firm, and the foliage has well nigh reached maturity, but the season at which the work should be done will depend in some measure on whether the Vines have been forced or not; for if they have, of course they will be in a more favourable condition, and, in that case, will bear rough treatment sooner than they otherwise would. Whenever done, a great point is to prevent their roots from drying, which may be done by having mats, thick cloths, tarpauling, or anything of that kind to lay over them as they are got out of the soil, and by keeping them frequently syringed or sprinkled with water from a fine-roset pot. In addition to this, the house should be saturated with moisture, and so shaded that it may be left shut without the temperature running higher than between 80° and 90°, as, beyond that there would be considerable risk of the leaves scalding, which would defeat the object in view. It will be found that the best way to set about getting the soil out is to open a wide trench first right along the front of the border, and, in doing this, cut all the roots as they are come at that may have strayed beyond. The space so opened out will afford every facility for following them on by working down the earth from among them with the aid of a sharp-pointed fork. While this is being done by a careful handy man or two, others, less trusty or expert, may be engaged removing it out of the way, by which means the work may be carried on more regularly and expeditiously than if conducted in a sort of hap-hazard manner. It frequently occurs that people try to improve the health and condition of their Vines by simply top-dressing the border, but a few inches of fresh loam placed there might

Tigridias Out-of-doors in Winter.—In the remarks which accompany the excellent coloured plate of the *Tigridia* given in THE GARDEN (p. 142), it is stated that "some cultivators allow the bulbs to remain undisturbed during the winter." In Wales we never think of lifting the roots, and they succeed admirably; all we do is to put a little light manure over them every winter, and we

as well be in the pasture for all the good it does, as roots, unless encouraged by heavy mulchings to draw them upwards, never feed so near the surface. This is readily accounted for by the extreme upper portion being subject to so many changes, not only as regards warmth, but moisture likewise, besides which, light penetrates some little way, and roots seem to have an inclination to avoid it and alter their course accordingly. On the other hand they are attracted towards manure, and this is why they grow upwards when it is applied as a surface dressing, and another reason is that then the conditions are more favourable for their travelling in that direction, as a mulching effectually excludes light and intercepts evaporation, the absence of moisture being one of the primary causes of driving them below to search for it at a lower level. It will be seen, therefore, if fresh soil is to be made available for them to feed on that it must either be buried by having a covering of manure to entice the roots to it, or it must be put near where they are, which is by far the wisest plan, and to do this at least 1 ft. of the top should be removed and a portion of that held back near at hand to scatter on again over the loam. Vines, like all other plants of a gross feeding nature, like sod fresh cut from a meadow, and the more loamy and fibry it is the better it suits them, and the less tendency has it for running or binding together. When such can be got, to attempt improving it by mixtures of any kind is the greatest mistake possible, as, except a few bones, whatever else is added tends to spoil and render it less lasting by hastening the decomposition of the vegetable fibres it contains, which, in their slow decay, absorb the gaseous juices and yield them up when called on by the rootlets to do so. Leaf mould is like poison, as, when it lays quiet and dry it is sure to generate fungus, and this, when it comes in contact with plants, attaches itself to the bark, which it permeates in all directions with a perfect network of the most minute threads, the effect of which is to utterly paralyse all healthy action and ultimately to destroy life altogether. Mortar rubbish and such like materials are useless, for if employed in any quantity they impoverish the soil by causing too rapid drainage, and render the mass so loose and hollow as to afford no stability to the roots.

S. D.

HINTS ON ORCHARD-HOUSE CULTURE.

It is unlikely that the cultivation of fruit trees in pots, in these useful structures, will increase in popularity, owing to the close attention the trees require during the growing season; and yet where amateurs can find time to give personal attention to them, it is most interesting as well as instructive to note the growth and development of bud into blossom and leaf, to watch and aid the setting of the blossoms, and ultimately to realise the full fruition of one's labours in the handsome and luscious fruits. It is needless here to go into any lengthened details of orchard-house culture, but a few seasonable remarks may be useful. The orchard house is generally a glass structure of any convenient shape, constructed for its adaptability to grow fruits well, and especially in districts where the climate is not suitable, or in places where the character of the soil is not well adapted to the culture of stone fruits. Whatever may be the form of the house—and it is worthy of note that trees will do well in the ridge-and-furrow, span roof, half-span, or lean-to—the internal arrangements are of the simplest. The most primitive of any that have come under my observation, has consisted simply of a shallow trench dug in the centre of the house, the soil being thrown out right and left, and made level. Very few persons would be content with this style, while a few shillings expended on gravel and edging tiles would form neat borders and paths, always pleasant to look upon. A narrow house may have a path down the centre, with a border on each side; while one over 18 ft. wide should have a bed in the centre, with a narrow border all round the sides. The paths should be about 2 ft. 6 in. wide, and the borders for the trees may be covered a few inches deep with Cocoa-nut fibre refuse. The roots should not be allowed to grow out at the bottom of the pots. I place the pots on bricks, or raise them on inverted pots, to prevent this, and also to keep out worms.

If the pots have been wintered out-of-doors, they ought to be taken into the house by the first week in February, and they will require but little attention until the blossoms are expanded. See that the trees are well watered at the roots, without giving them too much. Give air freely, but keep the frost out. It will always pay to have a heating apparatus. No doubt good fruit has been grown in succes-

sive seasons without any such aid, but in some cases there has been a failure of the crops because of the unfavourable character of the weather when the trees have been in blossom. The effect of frost is not felt very much if there be plenty of sunshine by day. It is during dull, cold weather, with a low temperature at night as well as by day, that artificial heat is required. When the trees are in flower, it is as well to shake them gently twice a day, to distribute the pollen. In this way, a good "set" is generally secured. Where the natural soil of the garden is unsuitable, it is very desirable to grow the trees in pots, as a small quantity of imported soil serves for each tree. Good clayey loam from the chalk is the best soil for stone fruits, and it answers equally well for Pears; a fourth part of good rotten manure ought to be mixed with it, and in potting, the soil should be well compressed with a wooden rammer.

Unless for the sake of variety, it is not desirable to grow many sorts of fruit trees. Six good Peaches are:—Hale's Early, Early York, Royal George, Grosse Mignonne, Bellegarde, and Deseze Tardive. Nectarines:—Lord Napier, Murray, Pine-apple, Violette Hâtive, and Victoria. A few useful Pears are:—Beurré d'Amanlis, Beurré Diel, Louise Bonne, of Jersey, Souvenir du Congrès, Marie Louise, and Williams' Bon Chretien.—J. DOUGLAS in "Florist."

SAUCERS IN STRAWBERRY FORCING.

It sometimes happens that some of our most useful horticultural appliances sink in the estimation of those who employ them, owing to their being so used that they not only fail to confer any benefit, but actually prove a source of loss and inconvenience. Saucers have long been used in Strawberry forcing, and may, undoubtedly, be made valuable agents of fertility, and yet many a crop has been ruined by employing them in an injudicious and indiscriminate manner. A practice exists of placing Strawberries in pans as soon as they begin to grow. If the plants are thoroughly well-rooted, and if the watering is conducted by an experienced person, no harm will result from it, and, where the pots, stand over hot pipes or flues, the saucers are useful for maintaining a healthy, moist atmosphere. But this practice has its dangers, and I would not recommend its adoption in a general way, as the water is apt to lie in the saucers just at a time when thorough drainage is most required, the effect being the destruction of the most important leaders of the plant. The real use of saucers is to enable the grower to administer such an amount of moisture to his plants as could not well be effected by any other means. Now, the question naturally arises at what period of their growth do they require to be thus saturated? The answer, which is easily given, is when they are fully furnished with well-developed foliage, and when the roots are in a very active state, a stage of growth never fairly reached until they are in flower. Before this time it would be safer to dispense with saucers altogether, and trust to careful waterings to supply the necessary moisture. In the earlier stages of growth the water cannot drain away too freely, and anything tending to produce stagnation will inevitably cause torpidity of the root, and eventually entail the destruction of those white fibres upon which depends the subsequent fertility of the plant.

I have known establishments in which Strawberries were always far from satisfactory, although there was ample accommodation for them. When, however, I saw that the plants were placed in pans before even the flower trusses had fully appeared, I was at no loss to account for the deficiency. In rejecting pans altogether we, however, run from one extreme to the other, and those who repudiate pans and saucers can have but a faint idea of what an important part they may be made to play in ripening off a heavy crop of fruit. In a previous number, "J. S. W." advocates the substitution of saucers of soil for the ordinary method, and I can believe that he finds his system beneficial. But useful as it may be in affording additional nutriment, to me it is open to the objection of not being able to supply sufficient moisture when the crop is swelling off. Perhaps for very early forcing there would be no difficulty experienced, but in April and May when we are liable to periods of hot, sunny weather, my experience has hitherto led me to believe that large plants cannot be maintained in a vigorous, healthy state, and heavy crops be ripened satisfactorily, unless there is provision for supplying an unlimited amount of water. The saucer, in fact, represents the delugings

which we find it necessary to administer to out-door plantations in hot weather; the amount of water which a well-fruited Strawberry plant will absorb in hot weather has often surprised me, and I have remarked that if this extra amount of moisture were not supplied, there was invariably a falling off in weight.

If hot weather should supervene when the fruit is three parts swelled, the plants, if luxuriant, will require much more water than can possibly be given them in the ordinary way of administering it, in proof of which I may cite instances when the pans were filled two and three times a day, and yet not a drop was left in them by the following morning. Let any one imagine the labour involved in administering this amount of water in the ordinary way, and how very likely the plants would be to suffer at some period of the day, especially when grown near the roof in a light, airy house. A strong-rooted Strawberry plant when in full fruit, with the functions one and all in a full activity, and subjected to a strong solar and artificial heat, is more liable to suffer from want of moisture than from a superabundance of it. There are times when it really appears to revel in sub-aquatic treatment, and, if, after a bright day, the pans be filled up with clean manure water when the house is closed, the appearance of the plants the following morning will fully indicate the beneficial effects arising therefrom.

With respect to letting the roots go out of the pot, my experience has led me to the conclusion that, if they go into fresh soil before the bloom is thrown up, an undue luxuriance of the leaf will be the result. I have often practised this method, but would never again allow the roots to work into the new soil before the plants were in flower, as, after that time, the increase of nutriment tells upon the fruit, which appropriates it to its own development. For this reason I would avoid strong stimulating manure in the earlier stages of forcing, but I have always considered soot water an admirable fertiliser at that time; it strengthens without stimulating, and may be freely used with perfect safety. There is not the slightest doubt that red spider is enabled to fully establish itself when not only moisture but nutriment is deficient; the foliage becomes deficient in substance, and cannot resist its attacks. By preserving the roots in a perfectly healthy state, never overwatering in the first stages of growth, and supplying abundance of moisture and food when the plants are in full growth, the leaves will acquire such substance that the enemy can make but little impression on them. JOHN CORNHILL.

Byfleet.

MILDEW ON STRAWBERRIES.

I SEE it stated in THE GARDEN (p. 146) that the liability of the Black Prince Strawberry to mildew is an objection to it as a variety for forcing, which is quite true, for, so far as I have seen, it never escapes mildew, and usually suffers to such an extent as to render the fruit quite worthless; but I think I can guarantee that if the following measures be taken to check the mildew clean crops of fruit will always be secured. It is rarely that the mildew appears to a noticeable extent before the fruit begins to swell, and if, when the berries have just set, the plants are thoroughly sulphured, it will keep it down till the fruit is all gathered. It does not do much good, however, to dust the sulphur on the plants, the syringe must be used. A quantity of sulphur, according to the number of plants to be gone over, should be thoroughly stirred up in a little skim milk till it be disintegrated, and then poured into a pitcher of water and applied right and left to the plants till they are well wetted on the upper and under sides of the foliage and berries also. There is no danger of overdosing the plants, and it may therefore be applied freely. The water should be kept stirred while it is being applied, otherwise the sulphur settles at the bottom, and the plants are apt to be smeared with it. If applied in the right way, and at the right time, it will hardly be noticed on the foliage, and none will be observable on the fruit when it is ripe. Of course the plants are never syringed after the sulphur is applied. I have forced from 600 to 700 plants of Black Prince every season for the past fourteen years, and have always had bright, clean fruit of good size. Prince of Wales is another sort that is subject to mildew, and may be cured in the same way. It never touches Héricart de Thury. With us the Black Prince is one of the best early forcers, and is ten days or more earlier than Héricart de Thury. J. S. W.

Strawberry Forcing in Pots.—My first Strawberries, consisting of Vicomtesse Héricart de Thury, are now swelling rapidly. I

examined them on St. Valentine's Day, and found on each plant from twenty to thirty fruit, which I shall reduce to a dozen. I can, therefore, with confidence corroborate all that Mr. Tillery says (p. 146) in favour of this variety.—R. GILBERT, *Burghley*.

Pine Houses.—The quotation Mr. Simpson makes, from what I wrote in THE GARDEN (p. 60, 1876) was in reference to amateur gardeners' glass houses, who are not supposed to grow Pine, and on that account I intentionally there omitted to mention them in any way. The article he thus refers to has nothing to do with the present question.—T. BAINES.

THE KITCHEN GARDEN.

Early Asparagus.—Good examples of blanched French Asparagus are now offered for sale in Covent Garden Market. They show a great improvement on the English-grown Asparagus offered for sale there a few days ago.—S.

Potatoes for Amateurs.—The list of Potatoes quoted (p. 151) as being suitable for amateurs for ordinary garden cultivation, includes nine kinds, three of which I should strongly object to recommend; but still that is not so bad as a list of fifteen kinds of Peas, especially as most amateur gardeners are limited to a space of from one-eighth to one-fourth of an acre in extent. In a list of Potatoes suitable for a small garden, I should not include coarse-growing kinds such as Victoria or Magnum Bonum, because these want more space than amateurs can generally afford; further than that they want fairly early kinds, in order that they may get the ground cleared in time to get in a winter crop of some sort to succeed the Potatoes. A few Ashleaf Kidneys should always be planted, and these should be followed by Early Union and Early Rose, then Snowflake, King of Potatoes, and Vermont Beauty; these are ample for the purpose, and are a good selection. If only three kinds are wanted, the first, third, and fifth will be the best to be had. It is not correct to say that the Old Handsworth Early and Porter's Excelsior are identical; there is no intimate connection between them; Porter's Excelsior is a larger cropper, and a far superior Potatoe to the Old Handsworth.—A. D.

Climax Potato.—In his complaint (p. 151) as to the quality of this Potato "J. D. H." realises one of the difficulties that beset those who are invited to advise as to the best kinds of Potatoes for certain soils. Under ordinary circumstances Climax may be regarded as one of the best of the American sorts, and ought to be good where Victorias, Regents, Snowflakes, &c., are good. That it is not so is difficult to explain, except on the supposition that the disease destroyed the haulm some time before the tubers were matured, and hence their watery character. That such a result has fallen to many kinds that are generally good I have this winter abundance of evidence, and no doubt many good kinds are being condemned for this very reason. Nothing is more probable than this; if the plant is practically killed before the tubers are more than three parts ripened their quality must suffer. "J. D. H." should not have made such a complete change in his chief crop at once. It would have been better to have obtained smaller quantities of some half dozen kinds, and then to have grown on the one that proved the best. For next season's growth I would advise that some of Climax be again planted, and also some of Snowflake, Schoolmaster, Dawes' Matchless, Magnum Bonum, and King of Potatoes. These are all good, dry eating, mealy kinds, and large croppers, white skins, and should do well in any fairly good soil. Climax, Snowflake, and King of Potatoes, should be planted in rows 30 in. apart, and Magnum Bonum, Schoolmaster, and Dawes' Matchless in rows 36 in. apart. If none of these kinds will give satisfaction, then, I fear, the soil in question must be utterly valueless for Potato culture.—A. D.

Boxes for Early Peas.—Seeing that "A. D." (p. 151) advocates the use of boxes for early Peas, allow me to say that for several years I have used boxes for that purpose, 3 ft. 6 in. long, 10 in. wide and 6 in. deep. The bottoms are separate, and are kept in their places by means of two pieces of tar-cord round each box. When the time comes for planting, trenches are made, the boxes are placed in them and the cords are untied; the bottoms are then gently withdrawn, the frames are removed, and the earth is pressed round the Peas; if these operations be all carefully performed, the Peas never seem to feel the transition, and succeed admirably. At present I have a number of these boxes sown with Peas under the stage of a greenhouse, and they will after a time be placed in a cold frame. In the summer the boxes come in usefully for flower seeds, &c. The advantages of having the boxes large are, that the Peas can remain in them a long time if the weather be unfavourable for planting.—J. J.

STORING ICE.

I HAVE nothing to add to Mr. Dennis's description (p. 59) of a well-constructed icehouse, though I should apprehend some danger from the drain, which ought not to have direct communication with the ice, but should be a trap drain or a common drain itself well stuffed with hay, through which the melted ice could percolate. I have had to do with some very scientific kinds of icehouses in my time, but I always found that elaborate structures were needless, and often useless; and that a rough and ready method of storing ice was the best. One method of ensuring thorough drainage is to place an old cart wheel at the bottom covered with straw. Lining the icehouse or ice well, too, with straw, is important, but this is too often done in an ineffectual manner. It is useless to place straw untied or in a loose manner between the ice and the walls, a seemingly large quantity of loose straw lies in a comparatively small space, when jammed by the weight of ice against the wall. Straw linings should be carefully prepared, pressed together as firmly as possible, and tied with three bands, as shown in fig. 2, with the ends even. Applied in this form the straw lining may be made nearly as compact as the masonry. In this way it not only becomes a powerful non-conductor of heat, but, by its symmetry and straightness, becomes a kind of internal thatch, carrying down to the well all moisture with which it comes in contact, only, if the icehouse should be of

well did the ice keep in this cold hole, with its walls of clay that there was scarcely ever any drainage at all, it was always ice; the inside was straw-lined in the usual manner, and fagots of brushwood were laid at the bottom. The ice was close by, and of course the water also, and about a yard of ice (in height) was filled in, water was run in till level with the ice; this was quickly converted into ice, and the process was continued till the place was full. This mass of ice was not covered over sometimes for weeks after being put together, but was there freezing away till a thaw or change was anticipated.

The person to whom this hole belonged, spent hundreds of pounds in experimenting with icehouses, but they were all too scientific. The last whim was a kind of round tower, wholly above ground, with a kind of casing of straw at some distance from the ice, thus enclosing a body of warm air around the building, but it never secured a pound of ice.

Ormskirk.

THOMAS WILLIAMS.

Outdoor Camellias.—Our Camellias out-of-doors here are in the same condition as those at Linton Park (p. 144). Were I asked what shrub has withstood the severe winter which we have had best? I would answer the Camellia, a fact of which we have ample illustration in the intensely green leaves and fairly-developed flower buds with which our plants are loaded. I have just been examining them to-day, and I think I never saw them look so green and healthy. I quite agree with Mr. Groom that the "Camellia might be planted out-of-doors in many places much more extensively than it is." I am of opinion that it would succeed perfectly in any county in the United Kingdom, provided it was planted in a position fully exposed to the sun throughout the summer.—CAMBERIAN.

Lean-to and Span-roofed Houses.—This is a subject on which I have lately bestowed much thought, and it is one, too, on which I have had considerable experience. If I wanted to grow stove or greenhouse plants for show I should have a span-roofed house running from north to south, for the sake of equal light; but if I wanted a house for Orchids I should have a wall built east and west, and a lean-to erected on the north for cool Orchids, and one on the south for Cattleyas and Dendrobies, having the pathways near the wall, and the stage near the glass. Thus the plants in pots would have the benefit of the span-roofed house, and I should have the wall on which to hang those on blocks. There they could be syringed without damping others, and, as they require more watering than those in pots, it would be the best place for them, and the whole house could get the benefit of the moisture given off by the wall. The old Begonia house at Kew was a half-span-roofed structure, having a south aspect, and a high back wall. There the plants grew vigorously, while in the new house, a span-roofed one, they have not grown half so freely. The old house that was on the south wall of the museum, at the bottom of the herbaceous grounds, was a lean-to; there stove plants grew splendidly, and so did the Cocoa-nut Palm, while in the Palm house the latter died. I had charge of the old house (No. 19 to the north of the then Grass department; that was a lean-to, and these Palms grew most satisfactorily; it had originally been used as a Cactus house, and there Cacti grew better than they have ever done since. I have had these plants in lean-to and also in span-roofed houses, and I find them to be more easily managed in the former. I am also acquainted with several places where they are grown, and in every case the lean-to houses contain the healthiest plants.—J. CROUCHER, *Sudbury House, Hammersmith.*

Germination of Seeds.—Notwithstanding the importance of this subject, there are few matters less understood, and for many kinds of seed a uniform practice is acted upon. No doubt it is right for a great many seeds, but not as regards all. Take, for instance, the common Primrose. I remember, many years ago, an eminent cultivator stating that nothing tried his patience more than waiting for some seeds of this Primrose to come up, and I well believe him. Some years ago, when I was actively employed in trying to multiply varieties of the Primrose for the garden, I found there was no way of getting seedlings up so certainly as by planting the parent plants in a sort of rough shrubby border plentifully overrun with weeds, and only now and then pulling a weed up by the hand, leaving the young plants and the weeds to struggle on together, and when they flowered removing what was good to more suitable quarters, for I was convinced that the presence and shade of the weeds were a great help to the Primrose seed. Some other seeds, no doubt, need the same kind of aid, while others require to remain longer in the earth than we sometimes have patience for. I fear we have yet much to learn in this matter.—A RETIRED GARDENER.

Fig. 1.—Straw lining; 2, central straw column; 3, aperture; 4, masonry.

Fig. 2.—Bundles of straw.

large dimensions, I would carry a column of these straw bundles right up through the centre of the ice, one on the other, from the top to bottom, chimney fashion. This will ensure drainage from the centre.

Icehouses should be constructed as near the water as possible from which the ice is to be obtained, certainly not in the pleasure grounds, as filling such houses is often rough work, but, wherever they are placed, let as much of the house be underground as possible, provided the drainage is efficient. The north side of a knoll or steep bank, accessible from other points, is a fit situation; in such a position, after as much ice as possible has been introduced by the doorway, and the latter is closed up, tons of ice can be introduced through the aperture at the top till the house is completely filled. This filling in the house from the top is important, and, where a natural brow does not exist, one may easily be formed, the material excavated from the icehouse going a long way to accomplish this. Never be in a hurry to shut up the house the day on which it is filled if it be during frost, especially such a frost as that which we have experienced this winter; on the contrary, let the frost get to it. And why should we pound and almost grind our ice when filling the house? What do we gain by it? "It lies close" says some one. I have no doubt if ice could be packed or built up in layers, as formed, it would not waste away so soon. Wenham Lake ice comes to us in solid blocks. However, by the following method masses of ice, whether in houses or pits, may be converted into nearly solid blocks, and the quantity of ice doubled.

I once had charge of what we called the ice-hole. This was on the steep north side of a large mound, covered with trees. The mound was formed of the excavations of some fish tanks (a series of which were close by). On the north side of this mound, as stated, the ice-hole was formed; yards below the bottom level ran a brook, into which the drainage ran, and so

PLATE CLXVIII.

SPOTTED GLOXINIAS.

Drawn by Mrs. DUFFIELD.

WHAT are Spotted Gloxinias? They represent a race of erect-flowering varieties having pale grounds spotted or punctured with chocolate, red, and reddish-brown. The size of the spots, their dispersion over the flower, and their colours vary, but, as will be seen, they are all exquisitely beautiful, and they contrast favourably with the varieties of red, crimson, purple, and other tints with which they are associated. As a rule, striking colours preponderate in Gloxinias, and it is of some value to have these in company with varieties possessing delicate tints. Hence the interest which centres round these newer types. There is no doubt that seed from a good strain of Gloxinias would be certain to produce some varieties more or less of a spotted character.

Seed of Gloxinias should be sown early in spring, so as to allow the plants an opportunity of attaining a sufficient size, in order that they may flower during summer in a way that will exhibit their true character; if sown about the middle of March, they will have the requisite time. The seed should be sown in an ordinary pan with 1 in. of drainage at the bottom, on which place a little Sphagnum. The soil should consist of equal parts of loam, peat, and leaf-soil, all sifted; add to the whole one-sixth its bulk in sand, it being essential to have the material of a loose open character, or the roots of the young seedlings will be injured in transplanting them. Fill the pan with the soil to within $\frac{3}{4}$ in. of the rim, pressing it down moderately firm, then water with a fine-rose, so as to close up the surface, and on this sow the seeds, not too closely, or they will become crowded, and consequently drawn up before they are large enough to pot off; cover very lightly, and place them in a temperature of 65°. As soon as the young plants appear, elevate them close up to the light, screen them from the mid-day sun and supply them with water, giving a little air during the day. When the leaves are 1 in. long, move the plants singly into 3-in. pots, using soil similar to that in which the seeds were sown, and at once replace them near the light, raising the temperature as the days increase in length. By the end of June they will require shifting into 4-in. pots, using the soil without sifting, and they should receive the treatment previously recommended. The best kinds should be marked for propagation, and the inferior ones discarded. When the flowering is over, give them less water, discontinue shading, and admit more air, so as to ripen the growth. When the leaves have died down, the soil must be allowed to become quite dry, and be kept for the winter in a temperature of 50°; cooler than this is not safe for any length of time. They generally winter best when the bulbs are allowed to remain in the soil and pots in which they have been grown; but as they become large and are in pots of a considerable size, this is not always convenient, in which case they should be stored in paper bags filled with dry sand, to preserve them from the air, otherwise they shrivel, and thereby receive serious injury.

To give a succession of flowers through the summer, a portion of the plants may be started about the middle of February, and a further supply in March; let the pots be proportionate to the size of the tubers—7 in. in diameter will be large enough for the second season. In potting just leave the crowns of the tubers on a level with the surface of the soil, and immediately they are potted place them in a temperature of 60° at night, and 65° or 10° warmer by day; if not put in heat as soon as potted the roots will rot; the soil ought to be in a slightly moist state when used, and little water should be given until growth has commenced. Treat them throughout the season as recommended for the previous summer as to heat, shade, air, light, and moisture. As already pointed out, their satisfactory flowering will depend upon their receiving abundance of light; a shelf over a path within a few inches of the roof is the best place for them, for in such a situation not only do they get the requisite amount of light, but they also receive more air, both being so essential to short, sturdy growth. This summer they will bloom well and increase considerably in the size of their roots, yet it is in the

third and fourth years after sowing that they will make the finest display.

When the bulbs get large they may be divided, retaining to each portion some of the buds with which the crown is furnished; but the most general method of propagation, and by far the most expeditious, is by leaf cuttings. If the leaves be taken off in the summer when fully matured with a portion of the leaf stalks, and this portion be inserted in 6-in. pots, drained and filled with half peat or loam and sand, with $\frac{1}{2}$ in. of sand on the top, and kept in a brisk heat, slightly shaded, and the soil moist, they will form healthy bulbs before autumn, or, if the variety that is to be increased be scarce, several may be produced from single leaves by cutting through the midrib on the under side in four or five places, and laying the leaves flat down on the soil in pots or pans, prepared as above, but sufficiently wide to admit of their being so placed; over each place, where the midrib has been severed, secure the cut parts on the soil with a pebble about the size of a cockle, at which points bulbs will be formed, which, when the top has decayed in the autumn will require to be wintered, and afterwards grown on in every way as recommended for the plants raised from seed.

Gloxinias are very valuable for decorating the stove or intermediate house in the summer season, continuing to bloom more or less for a considerable period. The flowers are very useful for cutting, and if placed in water they will last for several days, provided the plants have made their growth and produced their blooms in a thoroughly light situation, with the requisite amount of air to impart a sufficient substance to them, the latter an indispensable condition when they are required to be used in a cut state. The ability that the flowers of most stove plants possess to enable them to keep well when cut for vases, &c., generally depends materially upon the way the plants have been previously managed, but there are few so much dependent in this respect as are Gloxinias, the whole character of the plant being so much changed for better or worse, according to the conditions of cultivation. When well grown the leaves are stout and short, borne on stout foot stalks, with the flowers standing up well above the foliage; whereas, if grown either too moist or too hot, with insufficient light, the whole plant has a soft, flabby, straggling appearance that effectually destroys its beauty and shortens the duration of its blooming. By using a sufficient number of plants, and bringing them on at different times, a succession of flowers may be kept up from April until the end of September.

The varieties figured in our plate were from the collection of Messrs. Veitch & Sons, Exotic Nursery, Chelsea; their names are Nimbe céleste, Charme de Lutice, Irene, William Robinson, and Ami Thibaut.

Floral Committee Certificates.—Certificates, if they are to be of any value to the general public, should be granted with care; if they are marks of superiority, then the plants or florist flowers should be superior to those already in cultivation. If the plant be a fine-foliated one, it should equal or be superior to those which we previously possessed. My reason for making these remarks is that at the last meeting of the Royal Horticultural Society's Floral Committee, a first-class certificate was awarded to a meagre-looking Palm, in a very undeveloped state, named *Cyphokentia macrocarpa*, which I suppose was thought by a few of the Committee to be worth that distinction. Now, considering we have such Palms as *Calamus*, *Demonorops*, *Cocos*, *Arecas*, *Scaevothias*, *Kentias*, *Phoenix*, *Geonomas*, *Chamædoreas*, *Euterpe*, and others of the graceful type, and *Latanias*, *Livistonas*, *Licualas*, *Stevensonias*, *Verschaffeltias*, *Sabal*, &c., of the noble class, not forgetting *Thrinax* and *Chamærops*, we have great numbers from which to select, and in my opinion care ought to be taken to see that anything new should be in a condition to show its full grace and beauty before it is awarded a certificate, which the plant I saw at South Kensington the other day failed to do.—J. CROUCHER, *Sudbury House*.

Love-lies-bleeding for Harvest Decoration.—There are few plants that come in more usefully for this than *Amarantus caudatus*, or *Love-lies-bleeding*, and now is the time to get the seed, so that it may not be forgotten when the other annuals are raised. To secure a good supply of plants of it fit for the purpose, early, middle, and late sowings should be made. For our decorations last harvest

the red sort only was used, but a judicious admixture of the white and red sorts might perhaps be made to produce a pleasing effect.—B. S.

THE INDOOR GARDEN.

AN AMATEUR'S GREENHOUSE.

HAVING already given a rough notion of the structure, and of the manner in which I manage to keep out the frost, I would now supplement it by an account of the manner in which I provide for its furnishing, premising that I lay claim to no originality or skill, but simply to the fact of knowing what I wanted, and of a determination to do the best for meeting my wants. Two things I laid down to guide me in filling the house—to have nothing but good plants, for I felt that rubbish and indifferent things take up quite as much space as good ones, and that in making a selection the difference in price is not appreciable between what are recognised as really good plants, and those which, a little cheaper perhaps, are inferior in quality. The second point was to endeavour to have a succession of blooming plants, having especial reference to the earlier months of the year, not filling my house with a collection of any one sort, but having selections of a few of the best of several kinds of plants; and perhaps I may be able to make the matter clearer by giving the state of the house, &c., say during January.

I have kept the two sides of the house distinct, reserving one for hard-wooded, and the other for soft-wooded plants; the small shelf at the end of the house is occupied with four large-sized Camellias—*Mathotiana*, *Sarah Frost*, *Mrs. Cope*, and *Chandleri*. These, alas! will soon, I fear, be too large for the house; and I shall have to do with them as I have frequently had to do with *Azaleas*—exchange them away for smaller plants. *Sarah Frost* I must try to keep, for it is a reminiscence of a pleasant tour made in the middle of France with an ardent horticulturist, no longer with us. Besides these, I have eighteen others, smaller plants, consisting of *Lavinia Maggi*, *L. M. rosea*, *Valtoveredo*, *Mrs. Abbey Wilder*, *Montironi*, three or four of alba pine, imbricata, *Henri Favre*, *Countess of Derby*, *fimbriata*, *Eugénie de Massena*, and *Jubilee*. These seldom fail to give an abundance of blooms, and I never put them out-of-doors. When they have done blooming, I remove them to the lower house, stand them under the shade of the Vines, and leave them there all the summer. They like the shade, and, although it is not so good for the Vines, yet this is a secondary point with me. I am aware that most people place them out-of-doors, and where there is a careful person to see to the watering, that is all very well; but my experience in past years was that they were neglected, and, as no plants are so long in hanging out signals of distress in this matter, it was often not until the buds began to drop off that I found out the mischief that had been done, whereas in the house, even should the watering be neglected for a day or two there are no scorching rays of the sun to dry up the roots and injure the blooming.

To follow the Camellias I have about two dozen *Azaleas*—of course smallish plants, but large enough for me to be able to cut plenty of bloom from for vases or baskets for the house. Here again I have taken care to have good sorts, such as *Flag of Truce*, *Fascination*, *Gem*, *Grand Duchesse de Bade*, *Iveryana*, *Vesuvius*, *Stella*, *Madame Van Houtte*, *Duchess of Beaufort*, *Apollon*, *Sigismund Rucher*, &c. As they increase in size more rapidly than the Camellias, they have more frequently to be changed, and I would strongly advise those who wish to grow only a few to select the later-raised Belgian varieties. There can be no comparison between them and the older sorts, the flowers are so much larger, and the plants so much more floriferous. Here again, also, I adopt the plan of never putting them out-of-doors. They take their place along with the Camellias in the lower house, and until this year I have never seen any trips upon frost; but this year, owing, I imagine, to the long-continued frost, and my being compelled to keep up fire-heat, it has invaded me and become troublesome; I hope, however, to get rid of it by some of the numerous insecticides of which we hear so much. Along with these I have a few, and only a few, other hard-wooded plants—*Libonia*

floribunda, which, however, requires a little more heat than I can give it, I fancy; a few of the hardier *Heaths*, *Genetyllis*, &c. On the other side of the house I have at present some largeish plants of zonal *Pelargoniums*, which gave me more bloom than anything else during the winter months, some of Mr. Pearson's pink-flowered varieties being especially noticeable for this purpose. I am aware that a more even and higher temperature would suit them better, but I must be contented with what I can get, and all through the long and dreary time I have had from one to two dozen trusses of bloom. Besides these, I have about a dozen plants of *Cyclamen*, three or four *Tropæolums*, which will be very gay by-and-by; some pots of *Lachenalia pendula* and *tricolor*, which are very bright; some also of the pretty little white *Roman Hyacinth*; and some three or four dozen of show *Pelargoniums*, which are now in smallish pots, but which will be shifted by-and-by so as to give them more space to grow, and to fill up vacancies when some of the above-named are done flowering. *Cinerarias* I do not attempt, for I find that the temperature is not even enough for them, and experience has taught me that it is better to grow what will really do well than to be attempting things which only end in disappointment and vexation of spirit. I have a few pots also of *Primula cortusoides amœna*, which come in very usefully for cutting.

Such is the present aspect of the house; but I must prepare for its future gaiety as well as for the present, so I have just taken out of their winter quarters, where they have been covered up with leaves, and have started well, about seventy *Hyacinths*; these will be brought into the house in succession, and will make it quite gay and fragrant. In the lower house there are some pots of *Lilies*, *Vallotas*, *Calochorti*, *Ixias*, *Babianas*, and *Tritonias*, which will in turn take their place in the upper house; while there are also some two dozen *Fuchsias* and some tuberous-rooted *Begonias* for the later summer and autumn blooming. I reserve the lower house in autumn for *Chrysanthemums*, which afford such a fine variety of cut blooms in the dreary months of November and December.

In thus detailing the contents of my greenhouse, I must utterly disclaim all idea of doing anything in a super-excellent way. Of course great gardeners would laugh at my efforts, although I may say I have seen Camellias in many a big house not half so healthy as mine; they would find fault with the shape and size of my plants, and think that I had indeed made mountains of molehills, and magnified my gress into swans. But I have the satisfaction that it pleases myself and my friends. It must be borne in mind that I have no regular gardener, and that I have either to do or superintend the work myself—I cannot tell this man or that to do what I want, and that, in consequence, all failures must be laid to my own door; but I may say there is hardly a time when a gardener may pay me a visit but that I can show him something that he will be pleased to see, and something which is very probably new to him, although it is one of the disadvantages of living in a country place that so few do come. Nothing is more pleasant to a horticulturist than to be able to talk about, with one who loves the same pursuits, the things that are very dear to him, and to recognise that true brotherhood which art of whatever kind ought to bring; and my hope in giving this short account of my experience is, that I may be able to encourage someone who, like myself, has to fight against difficulties, and to whom it will be a pleasure to overcome them.

DELTA.

CHRISTMAS ROSES IN POTS.

I THINK it is a mistake to report these every year when they are wanted for flowering in pots. A gardener who has to provide a supply of flowers all through the winter, told me a few days ago he could not get on with his Christmas Roses, they would not flower, and he further said he should have to give up their culture altogether; and yet what charming and useful plants they are early in the year! and how acceptable they are when blossoms are scarce! I have now growing in a cold house a half-dozen plants in forty-eight pots, that were forced into bloom in a Pine stove a year ago, being put on a shelf close under the glass. I put the plants in a cold frame by way of hardening them off, and then placed them out-of-doors for the summer and autumn on an ash bed with other plants. At the end of October they began to show signs of throwing up their flower stems. The

plants were put under cover during frost, and they are now blooming with remarkable freedom. They have not been shifted, and all the stimulus they are receiving is a slight occasional surface-dressing with Clay's Fertiliser, which is washed into the soil when water is applied. The flowers are large, numerous, and of an almost snowy whiteness. I am in favour of confining the roots in a somewhat small space; in keeping the plants growing freely during the summer, as allowing them to take all kinds of weather during the time they are in the open air, of not shifting oftener than once in two or three years, and in applying some stimulus at the time of flowering. There are, no doubt, different strains of Christmas Roses, one being of greater freedom than the other in the way of producing flowers. I need scarcely state this is the variety or strain to be chosen by those growing in pots for flowers. If a few crowns of this form can be got, let them be divided and potted up into pots, just sufficiently large, and grown on into a size for forcing, giving one more shift into the blooming pots when requisite. Probably the best plan would be to bloom for two years in succession, or not more than three, and then plant out for one year for a thorough rest, potting up for further service a year after. These roots, when lifted, can be reduced a little by taking off a few of the outside crowns for stock, so as to reduce the roots to suit the size of the pots. There should be only sufficient space to put between the roots and the sides of the pots some good yellow loam. In planting out the single crowns for stock they should be put in a like compost, and of sufficient depth to enable them to root well into it. In this matter plants fit for flowering early under glass are provided, and with a little care and forethought a sure and most acceptable contribution of out flowers can be had at a time when their market value ranks at the highest.

D.

TREATMENT OF CYCLAMENS AFTER FLOWERING.

MANY who grow Cyclamens are at a loss to know what to do with them after they have done flowering, and the complaint is often made that when the growing season arrives they fail to make any satisfactory progress. When the Cyclamen has finished its allotted work, which will be by the middle of May, it will need a period of rest; but this rest must be a natural one; the bulb must go to sleep, as it were, in the manner in which Nature has ordained that it should do, and those who suddenly withhold water and dry off the foliage quickly will only have themselves to blame when they find their bulbs wholly inadequate to the work which they are expected to do. What would be the result if we were to cut off the supply of moisture from a deciduous tree when ripening its wood? Not death, perhaps, but certainly a ruined constitution. And yet bulbous-rooted plants are often treated as if they had no tissues to perfect; they are forced into a state of rest long before their time, and are then expected to come up to the mark in a hearty, vigorous manner when called upon to do so. A moment's reflection will convince any one how strongly opposed to reason such treatment must be. In the case of the Cyclamen the utmost care should be taken to preserve the foliage in a healthy state when taken out of the conservatory. The plants should be placed in a north frame, or in the partial shade of trees, where they are sheltered from scorching sun, harsh winds, and heavy rains. Water carefully, letting the soil dry out between each watering; the leaves will then die away gradually, but if some of them remain green and healthy it will not matter, as I have found them to flower just as well as when the foliage dies entirely away. As soon as the bulbs are well at rest, which they will be by the end of July, turn them out of the pots, shake away all the old earth, and plant them in a bed of light soil in the open air. Do not let them remain at all dry, but water them freely and they will start much stronger than when kept in pots. By the end of September they will have started into growth, and will be furnished with a quantity of healthy fibre. They may then be potted in a light, free, well-sanded compost, and then be placed in a cold frame, merely protecting them from heavy rains and frost. By the latter end of October they may be placed in a light greenhouse, where they will come into flower early in the year. These old bulbs do not flower quite so early as those grown from seed in a single season, but they make an effective display in the early spring months, and the neat habit and graceful appearance which distinguish the Cyclamen, place it in the first rank of winter and spring flowering plants.

J. CORNHILL.

THE ORIGINAL OAK-LEAF PELARGONIUM.

I WONDER what has become of this once highly-valued plant? Does it still survive in the window of some remote cottage or farm-house, where the pot of a former generation is still cherished by the old-fashioned inmates, like the once fashionable pigtail that might have been seen reclining on the coat collar of an aged shopkeeper thirty-

five years ago? It was about that period that I lost the last specimen that I ever saw of this plant, and I little thought at the time that I might never be able to replace it. If it still exists the following description will enable any one to identify it. Like all its successors, it produced the same kind of small unobtrusive blossom that they have, but the form, colour, and texture of the leaf were peculiar. It resembled an Oak leaf in size and shape. When fully developed, it had a dark mark running its entire length, and being somewhat glutinous to the touch it left on the finger a powerful and agreeable perfume. My recollections of the plant lead me to think that its leaves grew more in clusters than is the habit of the sorts now in cultivation. I have seen many of the so-called Oak-leaf Pelargoniums, but not one of them had the peculiar characteristics of the original.

B. S.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Large Poinsettias.—The fine Poinsettias exhibited at South Kensington on the 11th inst. by Mr. Parr, of Harrow Weald Park, were struck at the end of July or early in August from cuttings taken from old plants which had been placed out-of-doors in June to harden. The cuttings were put singly in 24-in. pots, and, when properly rooted, shifted into 6-in. pots, placed near the glass, and kept in a temperature of from 55° to 60°. By these means flowers of superior colour and quality may be had till nearly the end of February.

Chinese Primulas Damping off.—If the Primulas mentioned by "K. T." (p. 152) are old plants, that is, of more than one season's growth, the damping off of which complaint is made is a common occurrence. It is only with the greatest care that old plants can be kept free from this evil, as even the finest and most robust-looking plants will suddenly collapse and die, rotting off just above the soil. If the complaint relates to yearling plants then it is unusual and inexplicable. The worms alluded to are common in vegetable soils, and are, perhaps, rather the product of vegetable decay than the cause of it. The best soil for Primulas is decomposed turfy loam, some well-rotted manure, plenty of silver sand, and a mixture of broken pieces of charcoal. In such a compost Primulas should thrive well and be healthy. The mildew which attacks the Primula is very insidious in its operation. A flower may be seen to hang loosely on the stem; it may be pulled away, but this does not check the damp, which travels down the stem to the larger truss stem, which it infects with decay. Presently the old stem and truss collapse, and if this be but pulled away the mildew continues to travel down the stem to the plant, and into that also. The same occurrence takes place in the leaves, and in all cases, whether of leaves, stems, or flower stalks, too much care cannot be exercised in removing the decayed portion entirely, and thus prevent its further progress. Damping off at the base of the plant is so unusual with yearling plants that it is rarely found necessary to take any very special precaution with them, but in the case of old plants it is desirable that they should be somewhat elevated in the centre of the soil, sloping it off to the sides of the pot. In repotting these it has been found by such an experienced cultivator as Mr. Gilbert, of Burghley, to work in round the sides a good quantity of small pieces of charcoal, for securing free drainage, and it is of the first importance in all cases that the soil should be thoroughly sweet and porous.—A. D.

— If "K. T." (p. 152) will break up some charcoal rather finely, and put about a tea-spoonful of it round the base of each Primula she may save those she may have left. I put some round my plants after they had been in flower six weeks. I have had Primulas in full bloom ever since the middle of last September—one batch consisting of about seven dozen, and I have flowers now larger than a crown piece. The white insects of which "K. T." speaks, in my opinion, are the result of a stagnant condition of the soil about the roots, and the reason I think so is this: I have some capital Cyclamens, the drainage of one of which was stopped, and on examining the plants I found the soil full of the small white insects just referred to.—J. H., Bedford.

Portable Greenhouses.—Messrs. Dodds & Robb, of the City Road, have invented a portable greenhouse which promises to be useful where space is limited. It can be made of any size, large or small; it is fitted [with stages and side and top ventilators, all of which, together with the lights, can be taken to pieces in a very short time, and reconstructed when and where required.

Bouvardia Vreelandii.—This I find to be one of the best varieties of Bouvardia for blooming in midwinter.—CAMBRLEN.

BIRD-SCARERS.

CROPS in kitchen gardens, situated near woods, are always liable to be injured by birds; in such places, therefore, bird-scarers of some kind are indispensable. The conventional scarecrow, usually consisting, as is well known, of a stuffed figure impaled upon a stout pole, the whole being crowned with an antique hat, is indisputably useful, but it lacks two important attributes of life—sound and motion. The accompanying woodcut represents a bird-scarer which I have designed and made. It combines both sound and motion, and has been used in a large kitchen garden with good effect. The cross-piece (*a*) is affixed to the centre pole (*b*), so that it will revolve evenly; at the top of the pole the board or table (*c*), with its supports (*e*) must be fastened, in order to make the cross-piece revolve properly. The cross-piece is attached to the pole by means of the pin, ring, and nut shown at (*x*). At each end of the cross-piece is a staple, on which a strong swivel (*f*) is hung. Attached to the swivel at either end are light yet strong chains; at the end of each chain is a circle of light and strong galvanised iron wire, about 13 in. in diameter, tightly covered with some light and stout fabric, such as calico (*h*). The length of the chains must not exceed 18 in. Midway be-

Bird-scarer.

tween the swivel and the circular discs, a sheep-bell (*k*) should be fastened. On the top of the cross-piece a gable framework is erected (as shown in the illustration), from which must be hung another sheep-bell. The height of this bird-scarer should be about 8 ft. 6 in., and it should be placed in an open space in the garden, where seeds are coming up. When the wind catches the circular discs, it at once puts them in motion in all directions, and violently rings the bells, while the oscillation and revolving of the cross-piece, caused by the rapid movements of the discs, also rings the bell in the gable at the same time. The irregular and sudden motions of the discs are caused by the large surface of calico exposed to the breeze. To combine the two kinds of scarecrows, coloured cloths, &c., can be added to the framework.

Slough.

not always stating where they grow, but how they look in their native places, and some guide given as to the hardness of the southern species.

GARDENING FOR THE WEEK.

Greenhouse.

General Stock.—There is much more difficulty in managing greenhouse plants during such a winter as this than when it is milder, for when the temperature is so low for a number of weeks as to require almost continuous use of fire heat, even when no more is applied than is requisite to preserve the stock in a healthy condition, it always has the effect of exciting some plants to commence growth earlier than they otherwise would do. Hard-wooded plants need to be carefully treated in the matter of water, so as to prevent the soil from getting too dry or, on the other hand, too wet. Although the sun has not yet much power in drying the air, still within the next few weeks it possibly may render the more frequent application of water necessary, and, to ascertain the need for this, the whole of the plants should be examined every other day at least. Whatever tying yet remains to be done should be finished forthwith, as when any great portion of this work is delayed later in the season it interferes with the ordinary routine of other operations that in their turn come round. If any plants happen to be affected with brown scale they ought at once to be well washed with a moderately strong solution of insecticide. This also will not admit of being deferred, for if not done before the flower buds begin to move they are almost certain to be injured; this is especially the case with such plants as *Boronia serrulata*, *Eriostemon*, *Chorozemas*, *Croweas*, *Myrtles*, *Neriums*, and *Pimeleas*, on all of which brown scale will live and increase, though it does not thrive upon them so fast as on plants of a more succulent character. Its presence is easily detected by the dirty black deposit which it leaves on the foliage, and which, if allowed to remain, does more injury than the extraction of the sap on which the scale subsists. After syringing, before the foliage gets dry, it should be gone over and well sponged, for although the leaves of plants like these are too small to treat in this way individually, much of the dirty matter may be thus removed.

Plants for Succession.—Nothing connected with the management of a garden requires more consideration than due calculation, with a view to keep up a continuous supply of flowering plants. Without this, however ample the means at command, there is sure to be sometimes a much greater quantity of bloom than is wanted, with corresponding deficiencies at other times. If anything, the knowledge and observation necessary to successfully retard the flowering of plants is greater than that requisite to accelerate their blooming. Where no better structures for accommodating the collection of plants grown exist, than the old-fashioned lean-to house facing the south, it is a difficult matter to retard plants, as on houses of this description the sun, from the time of its getting much increase of power, exerts its full influence in raising the temperature, while for the next six or eight weeks the wind is frequently so cold, that to admit air sufficient to keep down the heat often existing through the middle of the day, would be to inflict serious injury upon many plants which are even making no leaf growth, and with nothing but their old mature foliage on them. It may be necessary to impress on all who attempt to keep back a certain portion of their stock of *Cinerarias*, *Calceolarias*, *Primulas*, and similar soft-growing subjects, and still more hard-wooded plants of such a nature as *Camellias*, *Azaleas*, late flowering *Epacris* and the like, that whatever is done to delay their time of blooming, should always be carried out before the flower-buds are much developed, as anything done by means of a lower temperature when they are near their opening period, is certain to interfere with their quality. Where there happens to be a lean-to house or roomy pit with an east, west, or, still better, north aspect, it will be found to be the greatest boon to those on whom the responsibility rests of keeping up at all times a considerable supply of flowers. If a few *Camellias*, *Azaleas*, *Acacias*, *Cytisus*, and *Epacris*—selecting those plants that were the latest to flower and make their growth last year—are at once removed to a place of the description above named, they will come into bloom several weeks after those that are located in structures more fully exposed to sunshine. A portion of all the soft-wooded subjects already spoken of, in their case choosing those that were the latest raised from cuttings or seed, will be alike useful. I may here observe, that although light is at all times of great importance to the well-being of plants, still, now, for some weeks, with subjects like the above, where little leaf growth is being made, the absence of as much of it as they would receive in structures more directly under the influence of the sun, will not have a like injurious effect, as it

"Meehan's Native Flowers and Ferns of the United States."—We have received a fresh instalment of this book. The character of the plates is well kept up; if anything, indeed, they improve. The printing, paper, &c., are the most satisfactory which we have ever seen in a book of the kind. Every lover of hardy plants must wish success to this important work. What we should like to see is a little more about the native localities of the plants,

would when active growth was going on. At the same time they should be so placed whilst here, that they will get the maximum amount of light afforded by the situation.

Camellias.—The earliest flowering plants of these that are now done blooming and that are commencing to make their growth must be encouraged by putting them where they can receive the requisite amount of warmth and a moist atmosphere. By accelerating their shoot growth, and the formation and development of their flower buds, they may be so managed with a sufficient stock to come on in succession as to be had in flower for nine or ten months in the year; but as no forcing can, with anything like a reasonable chance of success, be carried out in their case, it is in the early growth of some and keeping it back in others that their time of blooming can in this way be regulated.

Lapagerias.—Where trained examples of both the red and white *Lapagerias* are grown, they should at once be repotted, if they require it. For the first few years after being raised from cuttings or layers they are very slow growers, and must not be over-potted; but when they have attained considerable strength, they require more root room than many plants, otherwise they will not keep on forming their annual sucker-like shoots from the root of increased strength. Wanting, as they do, more water than the majority of plants, the pots in which they are grown must be well drained; good fibrous peat alone, with a little sand, is the most suitable soil for them. They are so effective for conservatory decoration, producing their flowers in long succession that they are well deserving of pot culture, as well as the more ordinary method of being planted out. They look well and show their flowers to advantage when trained on umbrella-shaped trellises. One point in favour of pot culture is that it admits of their being moved about from one house to another at different seasons of the year, when their requirements, as regards non-exposure to the direct influence of the sun through the spring and summer, whilst their growth is being made, can be better provided for than when in a fixed position.

Plumbago capensis.—The different purposes to which this fine plant can be turned are such as to make it deserving of being grown in quantity wherever there is room. In no way is it more useful than in small, say 6-in. pots, for associating with whatever happens to be in flower through the late summer and autumn. Plants cut back now and placed in a little warmth will, in a few weeks, produce growths which, when 3 in. or 4 in. long, can be taken off with a heel; they will root soon if accommodated with sufficient warmth. Examples that flowered last autumn, and that were then cut back and kept on growing slowly through the winter, may be at once repotted if they require more root room, but of the latter they do not need so much as many plants. Ordinary loam, a little sand and rotten manure, are all they want. If, after potting, they are kept in an atmosphere slightly close they will directly make growth that will flower before those allowed to come on slower.

Croweas.—These rank amongst the most serviceable autumn-flowering hard-wooded plants which we possess. If grown to a medium size in 8-in. or 10-in. pots few plants are more useful in conservatories late in summer, when flowers are scarce; but in order to have them in bloom before the autumn is far advanced they require special treatment, as they take more time to make growth and open their flowers than most plants that bloom from the current season's shoots. To effect this it is necessary to start them about this time in an intermediate temperature, first cutting them in to the extent of some two-thirds of last summer's growth.

Monochetums.—These *Melastomads*, though profuse winter bloomers, are not well adapted for cutting on account of the disposition which the flowers have to fall quickly. The little room which they occupy, blooming as they do as freely from twelve months struck plants in 6-in. pots, as those larger in size, renders them acceptable additions to the conservatory or warm greenhouse during winter and early spring. Where stock is wanted, if a small plant or two be now cut back, whether it has flowered or not, and put into an ordinary stove or intermediate house temperature, they will, in a few weeks, produce plenty of cuttings, which, taken off, and struck thus early, will furnish a supply for next winter.

Show and Fancy Pelargoniums.—These will now be making more growth, to encourage which, the night temperature should not be allowed to fall much below 45°, giving air on every fine day, still keeping the plants well elevated up to the roof glass, and setting them sufficiently far apart to prevent the under leaves being deficient of light. Whatever sticks and ties are needed for support, and to keep the branches open, should be at once supplied. Examine such plants as these, and also *Cinerarias*, *Calceolarias*, Tree *Carnations*, and everything else liable to become infested with aphides; and as soon

as any trace of these can be found, immediately either dip or fumigate. If these troublesome pests be not allowed to get much hold of the plants through the spring, they are easier to deal with than they otherwise would be.

Lilies.—Where considerable numbers of these are grown in pots, especially of *L. auratum*, their time of blooming will be so different under the same treatment, as to make them the most useful subjects for conservatory decoration that can well be cultivated; differing as they do in natural habit from that of most other plants with which they are thus associated, they are always an acceptable addition to whatever else may be in bloom. The various forms of *Lilium speciosum*, including *L. punctatum*, *L. album*, and *L. rubrum* will generally come on in succession. Pots of all the above, and many others similarly grown that are stowed away, must be carefully looked after, with a view to their being removed to a good light position, as soon as ever the shoots appear through the soil, for if allowed to remain even for a short time after they have commenced growth where they do not receive enough light, their stems will be drawn up in a way that no after treatment during the season can rectify.

Cinerarias.—At no time are these more serviceable than at the commencement of the year; but as they will not bear forcing, there is no means of having them blooming then but by early sowing. A little seed may now be put in.

Agapanthus umbellatus.—The different varieties of this fine old-fashioned plant are not nearly so generally grown as might be; they will bear rougher usage than most plants, without suffering to any appreciable extent. Their adaptability for standing, either in or out of flower, in porches, verandahs, or similar places about dwellings is not surpassed by any plants in cultivation. They will live and thrive with their crowns and roots so crowded in the pots as would prevent most plants making any progress; but though capable of bearing this treatment for a long time, they do correspondingly better with a fair amount of room. Any that have got too large may now be divided, cutting them into four parts, and putting them in pots that will afford sufficient room for a couple of years. By dividing them thus early, and at once placing them in a greenhouse temperature, where the roots will immediately begin to recover from the injury which they unavoidably receive during division, there will be less check to the season's growth than if the operation were deferred till later in the season.—T. BAINES.

Flower Garden.

Auculias.—Although the weather still continues to be rather cold, *Auculias* are making new growth very freely, and the rising trusses begin to demand attention, as well as watering and airing, for, unless air be judiciously admitted the flower stalks will not be stiff and elastic, and, on the other hand, exposure to a cold wind will cause the flowers to be cupped, whereas the tips ought to open out quite flat. Then it is not so easy to tell which plants require water and which do not, owing to the surface dressing deceiving the operator; increased attention in reference to this is therefore necessary. In ventilating the frame light should be tilted against the wind.

Carnations and Picotees.—Now that the weather is fine plants in beds should be looked over, the surface should be stirred with a pointed stick if it be wet, and in a day or two, if no rain falls, it will soon become dry. Make any plants firm that are loose, and where plants have died during the winter their places must be made good from reserves in pots. Plants in pots remain quiet as yet, but they will soon start into active growth, when they must be potted. When this takes place, to insure healthy, stocky growth, see that the lights are removed on all favourable occasions. It is now a good time to take cuttings of the perpetual-flowering sorts; the small side growths very speedily form roots if planted in small pots in fine sandy soil, placing the pots in a hotbed or forcing house. A correspondent asks for six of the best for flowering in winter; they are:—*Alegazier*, bright scarlet; *Annie Williams*, pink; *La Belle*, pure white; *Miss Jolliffe*, pale pink; *Proserpine*, scarlet; *Rose Perfection*, bright rose.

Dahlias.—It was stated last week that young plants, when rooted, were to be removed into a house where more air could be admitted than would be desirable for unrooted cuttings. This is preparatory to potting them into larger pots, which must be done as soon as the plants have, by their growth, shown that they are well rooted.

Hollyhocks.—The same remarks apply to these, as far as regards potting. Of course it is well known that these are much harder than Dahlias, and that they do not suffer even if frosts are admitted to the frames. It would not, however, be well to subject them to so

low a temperature; after being previously propagated in a warm house they must be gradually inured to stand a lower temperature.

Pansies in Pots.—These are now making good growth, and early flowers would, doubtless, open well, if we had genial weather and a little sunshine, which we do not yet obtain. It is necessary to examine the plants every night with lamp light, in order to destroy slugs, and if even one aphid were to be seen on a plant, I would have the frame famigated with Tobacco smoke. This ought to be done as a preventive before the plants are in full bloom. Such plants appear to most advantage when placed on a neat stage near the glass.

Primula cortusoides.—This, and all allied species in cold frames are now starting freely into growth, and a few of the plants should be removed into a warm greenhouse and, if possible, be placed close to the glass; there they will flower considerably earlier than those in cold frames. The pretty little *P. nivalis* with its dense tufts of delicate white flowers, *P. denticulata*, and others, require very similar treatment to that recommended for Auriculas and Polyanthus.

Phloxes in Pots.—Ours are starting very freely, but we did not put the plants into a greenhouse, and the growths are not yet sufficiently advanced to be taken off for cuttings. It is now time they were put in if a good bloom is to be expected at the end of the summer. Ours will be planted out as soon as the cuttings are taken off. If they were intended to flower in pots they should now be potted into 8 in. pots in rich soil.

Tulips.—The ground with us is very wet, and one can imagine what it is about Manchester and other parts of Lancashire and Yorkshire where the choicest Tulips are grown. It will be unnecessary to protect ours at present, but it would be folly to advise the fanciers to trust theirs to the frost at night. I recommend glass lights, as being far superior to coverings of thick felt or canvas of any sort, as protectors.—J. DOUGLAS.

Hardy Fruit.

Though the long-desired thaw has taken place, the succeeding wet weather has, as yet, prevented much progress being made; but we must, nevertheless, persevere, as the buds of many trees are getting very forward, especially those of Apricots, which are swelling perceptibly daily, and another few days of mild weather will induce some of them to expand. It is, therefore, very important that the protecting material should be got in readiness and all nailing or tying be accomplished forthwith. Where there are not proper appliances for protecting fruit trees on walls, such as glass copings and cases, frigi domo, or canvas blinds, a good protector can be made by laying a few poles slantwise against the walls, and fastening to them either hay or straw bands, Birch sprays, Spruce branches, or netting two or three ply thick. Of course, it is just possible that as good crops of fruit may be had without any protection as with it, but then it is a risk, as we can never depend on the weather, so it is better to be on the safe side, and protect the bloom in some way or other. The pruning of Peaches and Nectarines cannot longer be delayed; they are now starting into active growth, and every day's delay will now, in some measure, be injurious, canker and gumming being, as I believe, as much the result of untimely and unskillful pruning as of bad soil and improper drainage. The buds are too far advanced for the trees to have the usual washing or dressing with soapy water or other insecticide, so that, as soon as all nailing or tying has been completed, syringe both walls and trees with soap-suds, with tobacco water added, as a preventive, more especially against black fly, to which Peaches in the early stages of growth are liable. Any bush fruits that are yet unpruned should also have attention. The common mode of pruning these is much to be reprobated; by it nearly all the young growth is annually removed, whereas, if a reasonable amount of young wood were left, and a proportionate amount of old stems and spurs taken off, the fruit would be much finer and the trees would last longer in a vigorous condition. As soon as the ground is suitable, any trees requiring it should be top dressed with fresh loam or manure, and all newly planted trees—without exception—should have a mulching of stable litter, and be staked, to prevent wind-waving, the friction produced by which breaks off new roots as fast as they are formed. The long-continued frost having loosened Strawberry plants, they should now be well pressed into the ground; indeed, the whole bed would be the better for being thoroughly trodden, and well mulched with half-rotted stable manure. Taking fruit trees as a whole, there has not for some few years been such an abundant prospect, so far as fruit buds are concerned, as there is this season, for, with the exception of a few shy-bearing Pears, all kinds of fruit trees are literally covered with buds. Provided, therefore, spring frosts and mischievous birds keep off, this may be expected to be the best fruit season which we have had for years past.—W. W.

Kitchen Garden.

Vegetables for some time to come will be very scarce; it will therefore be desirable to anticipate this scarcity by paying extra attention to forced productions in that way. Early Cauliflowers have suffered severely, and it will not do to depend much on them. Asparagus from the open air will be very late, and so will Peas. Autumn planted Cabbages are much injured, and these also cannot be relied on; therefore, no pains should be spared either to produce forced vegetables or to forward early open-air crops, such as Peas, Broad Beans, Carrots, Turnips, Potatoes, Cauliflowers, and Cabbages, all of which may now be safely sown or planted on warm borders. The heavy rainfall that has prevailed ever since thaw set in militates against the accomplishment of seed sowing in general, and though the season is advancing, nothing will be gained by doing it whilst the ground is at all "pasty," but, as soon as practicable, let it be done, especially such crops as Parsenips and Onions, both of which require a long season. Garlic, Shalots, and Potato Onions may now all be planted; Chives and Sorrel may also be dug up, divided, and replanted, as neither of these do so well when allowed to grow in the same spot year after year; the same remark also applies to many kinds of herbs, which should now have their yearly overhauling for the purpose of division, transplanting, manuring the beds, and the like. Jerusalem Artichokes may now be planted; Globe Artichokes should have the protecting material removed from their base, and in lieu they should have a thick mulching of good manure; but first fill up any blanks that the frost may have made with offsets from the strongest stools. If new plantations are to be made, let the ground for them be heavily manured and deeply trenched, and, when planting, allow them plenty of head room. Rhubarb plots will now require their annual dressing, and new plots may be made by lifting a few of the largest roots, and cutting them into single eyes; such roots will produce the finest Rhubarb next season, but none should be pulled from it this season. Myatt's Victoria and Prince Albert are the two best varieties to grow, the latter being the best for forcing. Asparagus beds should now have a slight "pointing" over, but not so deep as to injure the crowns. Salt, guano, and wood ashes are all good manures for Asparagus, and if mixed with fine dry soil, they may be applied to the surface after the "pointing" has been done. It is yet too soon to make new plantations, but the ground for such should be got in readiness; it cannot be made either too deep or too rich. The late frost has so crippled many plantations of Broccoli, Cabbages, and Brussels Sprouts, that it will be advisable to pull them up at once, in order to prepare the ground for other crops, whilst there is, comparatively speaking, leisure for doing so. As soon as the soil is sufficiently dry, crops of Spinach will be much benefited by surface stirring, as will also Cauliflowers under hand lights, Cabbages, and autumn sown Onions. Earth up Peas in order to protect them from cold winds; at their present stage of growth sparrows eat out their points, and, when once they attack them, they clear off the lot, unless effectual steps be taken to clear the sparrows off by the use of the gun. Sow for succession such kinds as Advance, Dr. McLean, and Best of All. Sow in warm positions Lettuce, Cauliflower, Brussels Sprouts, and Coleworts, and prick out under hand lights or frames those that were sown in warmth a few weeks ago. A good breadth of Potatoes should now be planted on a sunny border, where, in the event of frost setting in, provision can be made for protecting them as soon as they appear aboveground. If no such attention can be bestowed on them it will be better to defer planting for another fortnight; in the meanwhile, however, the sets may be started in shallow boxes of leaf soil, and kept in any light structure from which frost is excluded. Forcing pits containing Potatoes, Carrots, Radishes, Lettuces, Asparagus, &c., should have their lights drawn right off on mild days, and be closed early in the afternoon in order to husband any little sun heat there may have been. Keep up a regular supply of Tarragon, Mint, and small salads by introducing a small batch at frequent intervals to the forcing pit.—W. W.

Extracts from my Diary, Feb. 18–23, 1878.

Watering Peach trees in orchard houses. Putting on nets and ribbon Grass on Apricots for protection. Planting Pear and Apricot trees. Thinning Grapes on pot Vines. Sowing on south border Dr. McLean, William the First, Marvel, and Standard Peas. Digging vacant ground. Earthing up Potatoes in frames. Sowing a batch of French Beans. Putting fresh soil on surfaces of Cucumber bed. Pruning and nailing Pears; also outside Vines. Planting Curranets out of cold houses on a north border. Making a fresh plantation of Royal Sovereign, Champagne, and Victoria Rhubarb. Getting in fresh batch of Strawberries for forcing. Cleaning, thinning, and tying Stephanotis. Shifting Beans from Melon house into Pine store for fruiting. Sowing Carrots and Radishes in frames; also sowing Mignonette in pots. Pruning and nailing Plums; also Red Currants

on walls. Potting Melons in 6-in. pots. Disbudding and thinning Peaches. Tying and staking Tomatoes. Potting Calceolarias. Sowing Petunias. Pruning and nailing Pears and Plums. Digging east border for sowing seeds. Planting Tripoli Onions. Tying pot Vines. Painting Vines in late Vinery. Disbudding Peaches. Propagating bedding plants. Potting Pelargoniums. Hoeing and earthing border of early Peas. Starting Muscat house. Propagating Centaureas and Iresines, and Mesembryanthemum cordifolium variegatum. Emptying Pine stove for Cucumbers. Looking over Apples in fruit room.

—R. GILBERT.

TREES, SHRUBS, & WOODLANDS.

THE CEDAR OF LEBANON AND OTHER CONIFERS.

ALLOW me to thank Mr. Woodall for his remarks in reference to the comparative merits of certain trees to which he has directed attention (p. 71), namely, the Deodar, the Cedar of Lebanon, *Araucaria imbricata*, *Cupressus macrocarpa*, and *C. Lawsoniana*. I note also the incidental remarks in allusion to *Araucaria Bidwilli* and the Norfolk Island Pine, but these being Conifers that will not withstand our climate need not be further referred to. The Deodar, as we all know, when young, and growing in sheltered situations, is always handsome, but, in its more advanced growth, it can hardly be unfair to say that it has utterly failed to realise the hopes and high promise of its earlier days, when first introduced into English gardens. Of the *Araucaria imbricata* there is still room to hope, and fair ground to believe, that in the southern and western counties of England and Ireland it will prove perfectly hardy. It is true it will neither thrive nor live long anywhere within the influence of smoke, but healthy and vigorous trees of it are occasionally met with in the uplands of the midland counties, and in other situations where least to be expected. Some few years ago I saw a dozen or more trees of it, 10 ft. to 20 ft. in height, in the most perfect health, growing in the pleasure grounds of Dunrobin Castle, in Sutherlandshire, not many miles from John o'Groats. The *Araucaria* possesses two properties of no small value in an ornamental tree, that is, it suffers less than most trees from high winds, and it needs no protection from cattle or animals usually occupying pasture land, donkeys excepted. When this latter peculiarity is more generally known, the *Araucaria* will doubtless become one of the most prominent and ornamental of our park trees. With regard to the *Cupressus macrocarpa*, I quite agree with all that Mr. Woodall has said in favour of that magnificent tree. Like the *Araucaria* it is, unhappily, rather tender, and is, therefore, only adapted to the south and south-western parts of the country, but in these localities it will be likely to prove one of the most valuable of this particular group of Conifers, and it is undoubtedly one of the most rapid-growing evergreen trees that we at present possess. These remarks apply only to the spreading and free-growing form of the species, of which there are many varieties. In the year 1858 I planted two small specimens of this variety on either side of the entrance gate leading into the grounds of the late Mr. Robert Byass, Neville Park, Tunbridge Wells. These two trees now measure respectively 50 ft. and 55 ft. in height, and not less than 25 ft. across the broadest part of the trees. In spite of the late protracted and severe frost, with the scorching and bitter east winds, these trees appear at present perfectly unscathed. No doubt both this and the *Araucaria* would thrive equally well on the shores of the western Highlands, where the Gulf stream greatly modifies the severity of the native climate. Three or four years ago I had occasion to visit that part of Scotland during the month of May, and on the eastern shore of what is known there as the Jura Sound, I found growing on the open and exposed lawn of an old Highland mansion and about a couple of hundred yards from the shore, a tree of the Indian *Rhododendron*, 10 ft. or more in height, in perfect health and covered with masses of scarlet flowers. On the same lawn was growing a plant of the common *Hydrangea*, 7 ft. or more in height and as much across. *Cupressus Lawsoniana* needs no comment beyond the fact that it is thoroughly hardy, and that some of the varieties are very handsome. The last of the five trees above alluded to is the Cedar of Lebanon, and the opinion expressed by Mr. Woodall, and his comments upon its merits,

led at once to a desire to add my testimony to its incomparable value as a hardy ornamental tree. During a daily occupation amongst trees, extending over a period of more than forty years, I have felt quite a growing affection for this glorious gift of Nature. Mr. Woodall may well refer to the grand old Cedars at Upper Gattin and Warwick Castle as samples of what the Cedar becomes under moderately favourable circumstances. Similar examples in various localities could be easily given, and notably those at Pains Hill, Surrey. There is, perhaps, no grander production in Nature than a Cedar or group of Cedar trees in maturity, or say a stage or two beyond that period. An old Scotch Fir, an old Oak, an Elm, a Sweet Chestnut, or gnarled Beech, may take the next position in point of picturesque beauty, but none of these approach in magnificence and grandeur the aspect of the Cedar. Having said thus much in behalf of this particular tree, it may seem unnecessary to add that during all these years I have, as often as opportunity offered, felt it an obligation laid upon me to influence all whom I could persuade to plant Cedars, and I look back with no small satisfaction at what I have been permitted to accomplish in this way.

With ample evidence to the contrary, in now so many instances throughout the country, it is marvellous to find so many persons clinging to the prevalent fallacy that the Cedar is a tree of slow growth. It is quite true that a Cedar or any other tree will grow slowly, planted, as they very often are, in exposed and draughty situations on open lawns; treatment to which many Cedars have been cruelly subjected. If Cedars are planted like other ordinary trees with the usual shelter of common plantations, and the latter properly attended to, and duly thinned—if this, I say, be done, I venture to assert that they will surpass both in height and bulk of growth the ordinary evergreen trees with which they are surrounded; and not only so, but this growth will be maintained. The Cedar is of course thoroughly hardy, and quite free from any capricious preference as to the soil in which it grows, provided it is fairly good of its kind. There are two localities within thirty or forty miles of London, where a considerable number of Cedars had been heedlessly planted along with the common mixed trees of the ordinary plantations; one of these extending over an area of about forty, and the other twenty-five or thirty acres. In both cases these plantations may have been made fifty or sixty years ago. In one case the soil is a mixture of gravel and clay, and the other a thin covering of heavy loam on a subsoil of chalk. In both the examples referred to the Cedars are the larger trees. Anyone caring to verify this statement, I shall have much pleasure in trying to secure an opportunity for their doing so.

ROBERT MARNOCK.

FENCING YOUNG TREES FROM RABBITS.

IF rabbits only are to be guarded against, netting 2 ft. high might do, but if for hares it should be higher; for one must allow for the snow helping the hare to her dainty morsel, the leading shoot of a Larch, or any of the Conifers, after which the tree does but little good. We have used 27 in. in length of wire to each young tree, well pegged down, and 4 in. in the earth, to keep the ground game from pushing the wire against the tree; and these, which form plantations, are now (although adjoining woods where hundreds of ground game are killed) fine, healthy trees. If it is a spot where it can be done without interfering with the shooting, I would recommend wiring the whole round, keeping the wire 6 in. below the surface, and making a notch in the top of each stake to prevent the netting slipping down. Many have the Grass growing near the trees cleaned away, but from my experience, I think it an error, for by the time the wire is worn out the Grass is a great protection to the bark of the trees. Of course the leading shoot and upper branches must be kept clear.—J. J. M.

Unless wire-netting is very carefully put up, and carefully looked after, it is of very little use against rabbits, when employed on a large scale, after it has been up a few months. The best way is to keep the rabbits down for three years. Young rabbits will force their way through an incredibly small hole, and old rabbits will get in when the snow drifts.—A. J. S.

If for guarding single specimens, 2 ft. netting would be quite sufficient, but for a plantation 3 ft. is quite little enough; and if the soil be light, I should recommend that a separate piece of netting from 8 in. to 1 ft. wide, be laid flat on the ground on the

outer side of the 3-ft. netting, thus forming, as it were, the capital letter L. This should be sunk slightly in the ground by removing the sod, placing the wire in position, and then replacing the turf. As rabbits always try to burrow under the upright netting close to the bottom of it, they are prevented from doing so by the piece under ground. I commenced nearly twenty years ago by using light wire netting; but have given it up for some time as I found that it soon rotted. Some allowed rabbits to get through in a very few years. There are always parts that escape being galvanised; these soon begin to rust and the work of destruction goes on rapidly. It is very little good wiring out rabbits unless the work is properly done. Bad work is merely throwing away money; cheap wire won't remain good five years, and can never be moved; whereas good strong wire can be taken from one plantation, when the trees are no longer in danger, to another. I have found No. 17 wire, 1½-in. mesh, galvanised, the best if the plantation stands by itself; but if joined to others, where there will be young rabbits, a smaller mesh is necessary, as they will get through when small, and some day the new plantation will be found to be well stocked with one's enemies, unable to get back through the meshes.—A SOLDIER

I have had considerable experience in fencing against rabbits, and the best advice I can give is: Plant your trees first, and when they have attained eight or ten years' growth, get your rabbits, but only in moderation. If, however, one lacks patience and will not wait, the next best thing to do is to erect wire fencing; but one might just as well try a brown paper fence as one only 2 ft. high; they would jump it without the slightest difficulty. It might do for a flower bed, because in summer rabbits have plenty of other food, and do not like the trouble of jumping 2 ft. I have tried wire fencing 2 ft. 6 in. above ground, and found it perfectly useless either for young plantations, or anything of which rabbits are fond. The cheapest in the end is good strong galvanised wire, 1½ in. mesh, 3 ft. high, well supported by posts every 6 ft. or 8 ft., and either 6 in. of wire underground or boards of that width. Even with all this 4000 yards would require constant watching, especially in autumn and winter, to stop the holes where the rabbits are found getting through. Wire at 6d. or 8d. per yard will be simply throwing money away. The cheap wire rots very soon, and rabbits get through it with ease. Anything under 1s. a yard would be useless expense, and only end in disappointment. It is needless to say that even ten or fifteen years' growth affords no guarantee from danger by rabbits. If kept in any quantity they will play sad havoc in severe weather with trees of considerable growth, especially Spruce, Larch, Beech, Mountain Ash, Hollies, &c. At such times, when the ground is covered with snow, say for a week or more, the best and only way is to feed them with hay or Turnips; even then choice trees should be protected by tying twigs and small branches round them.—"Field."

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS

Paulownia Imperialis.—In reply to Mr. Rogers (p. 143), as to whether the Paulownia usually forms its flower-buds in autumn or not, allow me to say that I have always found it to do so, and on that account have preferred its nearly allied congener the Catalpa, for, except in the southern counties, the flowering of the Paulownia is not satisfactory. In the spring of 1872, we had a grand display of bloom on a large plant of it at Ashburnham, in Sussex, and that was the only season up to that period in which it had escaped frost. Evidently young, vigorous, growing plants of it are more liable to have their flower-buds injured than those that have become well established, and that have made more compact growth; Mr. Rogers' testimony as to its having passed through this very severe winter unscathed, makes me hopeful that it may yet be more generally planted than it is with success.—A. HOSSACK, Rayley, Alcester.

Timber of Taxodium sempervirens and Kaori Pine.—I notice that Mr. E. H. Woodall says (p. 25) that "extreme rapidity of growth" is a characteristic of this Taxodium, which produces the famous red wood of commerce, so useful for many purposes, being both strong and durable. The timber of the Kaori Pine, another tree of extremely rapid growth, may also be mentioned as producing timber of the highest value, being considered equal to that of English Oak. It is used for masts for the British navy, no other tree being considered equal to it for that purpose. I see that no less than 70,000,000 cubic ft. of Kaori Pine were cut and sawn for home use and export in the province of Auckland, New Zealand during the past year, a fact which affords some idea of its value.—C.

Exochorda grandiflora.—The severe winter which we have had has at least had a beneficial influence on a bush of this beautiful hardy shrub—which, however, with me, at least, generally proves an exceedingly shy and uncertain bloomer, having, after the mild and

almost frostless winter of 1877-78, only produced a single raceme of bloom—by inducing it this year to show bloom on almost every terminal shoot, and on many of the lateral ones as well, much to my delight. I have been told that this shrub is in some places, especially near Weybridge, usually attacked by small birds, such as bullfinches, in the same way as these birds sometimes attack Apple trees, and that unless protected by a net or tiffany screen they eat out all the blossom buds, but they fortunately never so attack it here, though they are by no means so indulgent to the Apples trees in my garden.—W. E. G.

GARDEN DESTROYERS.

THE WINTER MOTH & THE LIME LOOPER MOTH.

CHEIMATOBIA BRUMARIA AND HYBERNIA DEFOLIARIA.

THESE two moths, though belonging to different genera, are members of the same family, and are very similar in their

Male and female moth and caterpillar of *Cheimatobia brumaria*.
Male and female moth and caterpillar of *Hybernia defoliaria*.

habits. The caterpillars of both species, where abundant, are very destructive to the leaves of most fruit trees and many other trees. The favourite food of the caterpillars of the winter moth is the buds of the Apple trees, but they also extend their ravages to the leaves of Elms, Limes, Willows, Hornbeams, Whitethorns, Hazels, and Roses. The caterpillars of the Lime looper are particularly fond of the leaves of Lime and Apple trees, but they also attack other fruit and forest trees. As the female moths of both species are entirely destitute of wings, or have only the merest rudiments of them, they are much easier killed or prevented from laying their eggs on the trees than most moths, for they are only able to crawl up the stems to reach the buds, near which they deposit their eggs. Several methods may be employed to prevent the female ascending the trees. A layer of birdlime may be placed round the stems of each tree, in which they would be caught if they attempted

to cross it; or a piece of sacking or some stout cloth, or a band of tow bound round the tree, and kept well tarred, would have the same effect. A kind of open wooden box, about 1 ft. high, may be made round the foot of each tree, which should be sunk an inch or so in the ground to prevent the moths getting under it, and kept well tarred or coated well with cart grease. A kind of collar of zinc or sheet iron, with the upper edge turned outwards, can be used in the same manner if well tarred, and will effectually prevent the females from ascending the trees. In the case of espaliers whatever means are used to prevent the females creeping up the stems must be applied to the supports to which the trees are fastened. If any measures of this kind have not been taken, search should be made on the trees for the moths, which, however, are difficult to find, as they so much resemble the bark in colour. It is during the months of October and November, and again in April and May that these precautions should be taken. The caterpillars may be destroyed by laying sheets under the trees and giving the branches a sudden shake or striking them with sticks covered with something soft, to prevent the bark of the boughs being injured, and collecting all that fall. On espaliers and dwarf trees they can be picked off before they have done much mischief by carefully looking over the bursting buds and opening any which have their points fastened together by silken threads. Most birds, particularly starlings, and titmice kill large numbers of these caterpillars; many are destroyed by various insects, wasps and ants. Many of the moths are killed when leaving the chrysalides by early and late frosts, which render the ground too hard to allow the moths to reach the surface; bad weather soon after they make their appearance is very fatal to them. The winter moth may generally be found in October and November, and even in December and January; some, however, do not leave the chrysalides until the following spring. The males generally appear first, and may be seen flying about in the twilight in search of the females, who, as soon as they leave the earth, begin to creep up the trees, as they are unable to fly; they deposit their eggs, which are very small, of a bright green colour, and firmly glued to the tree, singly on the buds and twigs. Each moth lays about 200 eggs. The caterpillars are hatched as the buds are bursting. At first they feed on the tender part of the buds, covering them with fine threads; afterwards they attack the young fruit and leaves, which they fasten together to form a shelter; these they soon reduce to skeletons, and then take up fresh quarters. If in large numbers they soon strip a tree of its leaves, causing it much injury, particularly in the case of fruit trees. Towards the end of May they have usually attained their full size; they then let themselves down to the ground by threads, creep under clods or stones, or bury themselves a few inches below the surface, and become chrysalides, in which state they remain until the beginning of winter or the next spring. The habits and economy of the Lime-looper moth are so similar to those of the winter moth that they need not be mentioned here. The male of the winter moth measures about 1 in. or $1\frac{1}{2}$ in. across the wings when fully extended, the upper pair of which are brownish, reddish, or pale, grey, with several darker, fine, wavy, transverse lines; the lower wings are somewhat paler than the upper. The body, thorax, and head are yellowish-grey, and very slight in proportion to the wings. The female is wingless, or has only the rudiments of wings; her body is $\frac{3}{4}$ in. long, tolerably stout, and darkish grey in colour; if the rudimentary wings are present they have two darker transverse lines. The caterpillars, when fully grown, are about $\frac{3}{4}$ in. in length; their heads are greenish or brownish, the bodies are green or yellowish-green of various shades, with several longitudinal whitish lines; they are twelve-jointed, the first three, the ninth, and last have each a pair of legs; as these legs are at either end of their bodies, when they wish to move they draw up their bodies in a loop, bringing their anal legs close to their front ones, hence the name of loopers; they then advance the front part of their bodies as far as they can stretch, thus becoming quite straight again. All the caterpillars of this family move in this manner, and as they seem as if they were measuring whatever they are moving on, the family has been given the name of Geometridæ, or earth measurers. The chrysalides are of a yellowish-brown colour.

The males of the Lime looper moth are considerably larger than those of the winter moth, measuring $1\frac{1}{2}$ in. or $1\frac{3}{4}$ in. across the wings; the upper pair vary much in colour, but generally are yellow or yellowish-red speckled with black, with the base of the wings reddish-brown and an irregular transverse band of the same colour nearly midway between the edge of the darker base and the end of the wing; in the middle of the lighter space, near the front margin, is a dark spot. In some varieties the base of the wing is not dark. The lower wings are greyish or brownish-white with a central black spot. The antennæ are very deeply toothed. The females are entirely destitute of wings, and are about $\frac{1}{2}$ in. long, of a yellowish-white colour, with several black spots on the back. The caterpillars are nearly $1\frac{1}{2}$ in. long, with their feet arranged in the same manner as those of the preceding species; their heads are reddish-yellow, their bodies are reddish or yellowish-brown, rather darker on the back, with a pale yellow band on either side, in which, at the middle of each joint, is a reddish spot with a white centre. When at rest it assumes the attitude shown in the woodcut. The chrysalides are reddish-brown. S. G. S.

NOTES OF THE WEEK.

Cycads and Camellias.—These, associated with tree Ferns and other fine-leaved plants, are now strikingly effective in the large conservatory in Mr. Ball's nursery at Chelsea. The Camellias, which consist of large specimens, are judiciously intermixed with the variously tinted differently formed fronds of the Cycads, Palms, and Ferns, and arranged in this way, a conservatory is rendered much more enjoyable than when furnished with straight and formal stages, filled with showy but common plants—an arrangement too often found in private gardens.

Æchmea Mariæ Regina.—This is, without doubt, one of the most useful and attractive of Bromeliaceous plants. Even when not in flower, if well grown, it makes a good table or vase plant, on account of its stiff silvery-green leaves, and when furnished with brilliant rosy-purple inflorescence, as we now find it in Mr. Williams' nursery at Holloway, it is a plant at once effective and striking.

Varieties of Asparagus.—Few plants are more graceful in habit than the different varieties of Asparagus, of which there are now many in cultivation. For table decoration, or for the ornamentation of sideboards, where light, lace-like greenery is needed, few plants will answer better. We lately saw a large and varied collection of the more ornamental kinds of Asparagus in Mr. Ball's nursery at Chelsea.

Lasting Properties of Orchid Flowers.—The length of time during which some Orchid flowers will last uncut in good condition is almost incredible, a remark which appropriately applies to those of that showy Orchid, *Odontoglossum Halli*, plants of which are now finely in bloom in Messrs. Veitch's nursery at Chelsea. On a specimen of this bearing two graceful flower spikes 3 ft. in length, the first blossoms opened quite three months ago, and yet even now there is scarcely a decayed flower to be found on the plant in question. Orchids like this, which flower for so long a time during the darkest months of the year cannot well be too extensively grown or too highly valued.

Sarracenia purpurea.—Numbers of plants of this in Mr. Williams' nursery, Holloway, are now furnished with large, crimson, globular, nodding blossoms, which contrast effectively with the large and fully-developed pitcher-like appendages with which they are associated. Though hardly this *Sarracenia* is handsomer when grown in heat than out-of-doors.

Lachenalia orchideoides.—This is now in bloom in Mr. Ware's nursery, Tottenham. Its flower spikes, thickly beset with violet-tinted pale blue blossoms, upright rather than pendulous, render it distinct and really handsome, though perhaps not so showy as some of the better known kinds. *Cortusa pubens*, a larger and more robust species than *C. Matthioli*, is also in bloom in the same nursery.

After the Frost.—I have just seen some tufts of Winter Aconite and Snowdrops in a cottage garden, which had, the latter especially, all the freshness and purity of hothouse flowers. Indeed they seemed to have, during the short periods of sunshine of the last few days, shot from the ground, as it were, too suddenly to become soiled, but in reality it was doubtless the shelter of overhanging shrubs which had prevented their having become rain-splashed. The tallness of the

Snowdrops was very remarkable, both flower stalks and leaves standing boldly erect, fully 10 in. high, as though their having been frost-bound had made them more susceptible to the influence of the succeeding mild weather and rain. Crocuses are showing colour, and Daffodils are pushing their soft green spears upwards, as if really glad to be once more free from the shelter of mother earth. The yellow winter flowering Jasmine has also rushed into bloom with equal rapidity, and the severe weather has caused its flowers to burst open simultaneously, that is, much more so than is usually the case in mild winters. My Roses, too, have pushed forth, I am sorry to see, their tender young growth during the last few days, and fruit-buds are everywhere swelling fast.—B.

Primula Cashmeriana.—This is the name of a pretty *Primula* belonging to the *P. denticulata* group, now to be found in Mr. Williams' nursery at Holloway. The plant is sturdy in habit, and its leaves are covered with a sulphur like farina. The plants in question are not yet in flower, but their blossoms are described as being produced in very large heads, and of a rich purple colour with yellow centres.

Camellias at Chelsea.—Notwithstanding that it has been a bad season for the production of good *Camellia* blooms, the *Camellia* houses in Messrs. Veitch's nursery look better than we ever remember to have seen them. Plants in pots consisting of large shapely specimens are coming finely into flower, whilst those planted out permanently are full of buds, which promise soon to open. All the best and new kinds are represented by well-grown plants, and when in full bloom will be well worth inspection.

Amaryllises at Holloway.—Seedling *Amaryllises* now enliven the houses in Mr. Williams' nursery at Holloway with their large and brilliant blossoms. In most cases the plants are exceedingly strong, bearing two and even three large spikes of flowers. Though it is by many thought almost impossible to improve greatly on the kinds of *Amaryllises* now in cultivation, there are in this collection some with larger flowers than usual, and, moreover, the plants appear to be more floriferous. Arranged in a cool house, the plants alluded to contrast effectively with *Cyclamens*, *Cape Heaths*, *Tree Carnations*, and other plants in flower with which they are associated.

Angræcum sesquipedale superbum.—This fine variety of a well known *Orchid* is now in flower in Messrs. Veitch's nursery at Chelsea. Its blossoms are nearly twice the size of those of the ordinary type, and they are of great substance, and as white as ivory.

Dendrobiums in Small Pans.—There will shortly be a fine display of these in Messrs. Veitch's nursery, Chelsea. They consist of such kinds as *D. crassinode*, *D. Wardianum*, *D. Devonianum*, &c., all remarkably well grown in small, shallow pans. The pseudobulbs are of good size, and, being thoroughly ripened, owing to their being suspended close to the glass, they promise to produce flower spikes from every joint. Some, indeed, are already fully in bloom, and long rows of them are coming on in succession.

Croton roseo-pictum.—This is one of the finest of the new *Crotons* now in cultivation. It is good in habit; its leaves are large in size, and its colour, a combination of different shades of crimson, rose, and scarlet, renders it a very striking plant at this dull season of the year. Some good specimens of it may be seen in Mr. Bull's nursery, Chelsea.

? **Flowers of *Iberis semperforens* at Christmas.**—This useful hardy plant, now in flower in quantity in Mr. Parker's nursery, Tooting, might with advantage be grown for supplying cut flowers at Christmas, or even earlier. Plants of it lifted from the open ground in September, potted, and placed in cold pits or frames for a month or so, and afterwards introduced into a gentle heat, might easily be had in flower during the duller part of the year.

Dendrobium eudocharis.—This pretty hybrid *Dendrobium* is now in flower in Messrs. Veitch's nursery, Chelsea. It is the result of a cross between *D. japonicum* and *D. heterocarpon*. It is dwarf and compact in habit, and its flowers, which are produced in profusion, are creamy-white with a pale yellow-purple striped throat. It is a valuable addition to our collections of *Orchids*.

Hardy Flowers' at Tooting.—The effects of the few days of mild weather which we have had are clearly visible as regards the growth of hardy flowers, and, should it continue, many of them will soon be in bloom. In Mr. Parker's nursery, even now, *Crocus Imperati* and the pretty blue *C. Sieberi* are in full blossom, as are also *Galanthus Imperati* and *G. plicatus*; the Giant *Hellebore* (*Helleborus stiltifolius*) is also producing a few fine blooms, varying from pure white to deep rose; the common Christmas Rose (*Helleborus niger*) has also been in flower for many weeks past; the *Cape Poinsettia* is likewise flowering with great freedom, and *Saxifraga*

Burseriana and *S. Rocheliana* are also opening their flowers. Hardy *Cyclamens*, too, in Mr. Barr's ground are in flower, where a little protection has been afforded them, and those growing in masses amongst the Grass under trees will shortly be in bloom.

NOTES FROM KEW.

Hardy Plants.—The mildness of the weather during the past fortnight has awakened quickly many of our early spring flowers. Conspicuous among these are the various kinds of *Snowdrops*; besides the common *Galanthus nivalis*, there is the variety called *Sharlocki*, which may, at a glance, be distinguished from the ordinary form by the blotch of green on the outside of the large petals and much longer and narrower bracts, thereby rendering it very distinct. The plaited-leaved *Snowdrop* (*G. plicatus*), though a very old introduction, is not so common as it should be; it has large flowers and broad leaves, which differ from those of all the other kinds by being folded at the back. It is a native of the Caucasus. Undoubtedly the choicest of all is *G. Elwesi*, which grows about 6 in. high, and has broad, flat leaves of a very deep green. It produces large, drooping, pearly-white blossoms, with the small inner petals wholly green, except a narrow, crisped, white margin. It is a native of Smyrna, and was found by Mr. Elwes on the summit of the Yaman-lardagh Mountains, in 1874. One of the best of the spring flowering kinds of *Crocus* is *C. Imperati*, a robust and free-flowering kind, with flowers 2 in. across when fully expanded; these are fawn coloured, heavily pencilled with purple on the outside, and of a pleasing lilac hue within, contrasting finely with the bright yellow stamens. It is also sweet scented. Its native habitat is on the mountains of South Italy, &c., at high elevations. The *Alatavian Crocus* (*C. alatavicus*) is a new claimant to public favour, and though not so showy as the last, is, nevertheless, very pretty. Its flowers are white with yellow spots at the inner base, and finely grained on the outside with deep purple. It is a native of the Alatau Mountains, and is one of the numerous introductions of Dr. Regel, of St. Petersburg. *Crocus chrysanthus* var. *fusco-tinctus* much resembles the preceding in the markings of the flower, but the ground colour is yellow. The variety *fusco-lineatus* differs in having the black markings disposed in fine lines on the outside. Both inhabit the Bithynian Olympus and elsewhere in Asia Minor. The *Bulbocodium*-like *Colchicum* (*C. bulbocodioides*) is a very desirable plant, much in the way of *C. montanum*, but the flowers are globular in form; they are produced plentifully and are of the same delicate blush tint as those of *C. montanum*. The *Vernal Bulbocodium* (*B. vernum*) has blossoms of the same colour, but they are much longer and have narrow, attenuated petals.

Greenhouse Plants.—*Boronia negatigma* though not one of the showiest of the genus, is highly desirable on account of the delicious aromatic fragrance possessed by the blossoms, which are globular, nearly $\frac{1}{2}$ in. in diameter, dull purple on the outside and yellow within. They are borne in profusion on very slender branches furnished with small, Heath-like leaves, arranged in whorls. Such a charming acquisition as this cannot be too strongly recommended, as it is one of the hardiest of the *Boronias*, as well as one of the easiest to manage, and well adapted for introducing into dwelling rooms during the flowering season. It is of Australian origin, being found in the vicinity of King George's Sound. The round-leaved *Xanthosia* (*X. rotundifolia*) is a very remarkable Umbelliferous shrub also from Western Australia. It grows about 2 ft. high, with leathery, heart-shaped leaves, which are sharply toothed, and it produces terminal clusters of small flowers, each enclosed in membranous white bracts much resembling a *Hydrangea*; besides this, it has not much beauty to recommend it for general cultivation. The Jasmine-flowered *Rhododendron* (*R. jasminiflorum*) is certainly one of the most beautiful of that family. It attains several feet in height, though it flowers freely in a small state. The leaves are small and oval, and the blossoms have a narrow tube 2 in. long with spreading petals $1\frac{1}{2}$ in. across, both of waxy whiteness, contrasting beautifully with the deep red stamens rising from the tube. It was introduced in 1848 by Messrs. Veitch from Mount Ophir, where it grows at 5,000 ft. elevation.

Stove Plants.—*Eucharis candida*, a bulbous plant of rare beauty, at first sight reminds one of its better known congener *E. amazonica*. It has ample foliage and pure white blossoms, but it differs in its leaves being larger and its blossoms smaller, with the divisions gracefully reflexed, and also in the corona being longer, more deeply toothed, and having a zone of yellow at the base. The flowers are produced in the same umbel-like manner as those of *E. amazonica*, and expand in quick succession. It was introduced by Mr. Bull from the United States of Colombia, and was first figured in THE GARDEN in 1876, Pl. XVI. *Imantophyllum miniatum* is another

very handsome member of the *Amaryllis* family, belonging to the non-bulbous section; it has large sword-shaped leaves, that spread in a fan-like manner, and are of a very dark green. The flowers which are large are borne in a dense terminal cluster on a stout compressed stalk; their petals are 2 in. long, bright orange scarlet in the upper half, and yellow in the lower. It is a native of Natal, and therefore may be grown successfully in a warm greenhouse.

Orchids.—Amongst those now in flower may be mentioned *Trichosma suavis* (syn. *Eria cylindropoda*), which, though an old introduction, is one of the rarest of East Indian Orchids in cultivation. It has short, slender stems, with oval, leathery leaves, and produces its flowers in short, loose, terminal racemes; they are of the size and form of those of the old *Celoglyne media*, with a golden lip, the edges of which are marked with deep brownish-red streaks; but the chief point of attraction is their delightful fragrance. It was first discovered and sent to Chatsworth by the late Mr. Gibson from the Chirra district in the Khosea Hills, where it was found growing upon trees in densely shaded woods at high elevations. *Dendrochilum plumaceum*, a native of the Philippines, is represented by a very fine specimen bearing a score or two gracefully drooping spikes of small, pellucid, ivory-white blossoms, which are very sweet-scented. Though not showy, this fine Epiphyte has a remarkably pleasing effect, and well merits a place in the most select collection. *Leelia superbiens* is a truly superb plant, being the largest and statelyst of the genus. So handsome is it, that it is one of the few tropical flowers which specially excite the admiration of the natives of Guatemala so that they plant it in front of their dwellings. It is found at considerable elevations growing abundantly, near the town of Comolapa, in the crevices of exposed rocks, but sheltered from north winds, where the stems attain a height of 2 ft. or more, with leaves large in proportion, and produces flower stems frequently 12 ft. long, terminated by a dozen or more of large purple blossoms. *Dendrobium Hillii*, named in compliment to the present Director of the Botanic Garden at Brisbane, is one of the handsomest of Australian Orchids inhabiting the vicinity of Moreton Bay. It is nearly allied to the better-known *D. speciosum*, but may at a glance be distinguished by its more robust habit and larger blossoms, which are cream-coloured, copiously spotted with purple, and borne in long dense racemes, terminating the stout stems with large leathery leaves. *D. Findlay-anum* is a very distinct kind with peculiar knotted, erect stems and large bluish-tinted flowers with a spreading shallow lip, white, with a central blotch of pale yellow. W.

ANSWERS TO CORRESPONDENTS.

Ferneries.—I am about to erect a stove Fernery with a north aspect, and I shall be glad to have the advice of others as to what plants besides Ferns I can grow with advantage in the same house. I presume I can grow Palms, Alocasias, fine-foliated Anthuriums, and Marantas. Will Cycaeds grow as well in a house with this aspect as where they can get the sun? Could I grow any flowering plants along with them?—**AMATEUR.** [All the plants you name, including Cycaeds, will grow well in such a house, and for flowering plants nothing would do better or be more suitable than tuberous-rooted Begonias, of which the variety is now legion.—W. H.]

Good Standard and Bush Roses.—The frost having killed about half-a-dozen of my standard Roses at Boxmoor would you name some of the best to replace them? Also a few bush Roses that would do well?—**J. D. A.** [Baron de Bonstetten, maroon; Beauty of Waltham, carmine; Duke of Edinburgh, scarlet; Madame Alfred de Rougemont, white; Mlle. Thérèse Levet, rose; and Star of Waltham, crimson, are six good standard Roses. The following selection as bush Roses includes most shades of colour, viz.—Alfred Colomb, Charles Lefebvre, Comtesse de Serény, Countess of Oxford, Dr. André, Fisher Holmes, Francois Michelin, La Rosière, Louise Darzacs, Madame la Baronne de Rothschild, Marguerite de Castellane, Mlle. Eugénie Verdier and Safrano.—A. W. P.]

Planting Carriage Drives.—In answer to "Beta's" inquiries (p. 132), allow me to remark that few things are more difficult than giving advice in matters connected with landscape gardening, unless one is thoroughly acquainted with the ground upon which the work is to be carried out. I have always considered that carriage drives should be planted on either side with such trees and shrubs as will produce the greatest variety and succession of flowers and foliage during the year, in order that the aspect may be as cheerful as it is possible to make it. The list of trees and shrubs suitable for the purpose is a long one; it will, however, only be necessary to give the names of some of the most desirable. What is perhaps of equal importance is the knowledge as to how the outline of the shrubby border is to be formed; this should neither be straight nor parallel with the line of roadway, but should be naturally furnished with recesses here and there, and a greater width of turf in some places than in others. This will afford an opportunity for planting isolated shrubs or plants upon the turf, a feature which, in my opinion,

greatly improves the appearance of carriage drives. The ground should also slope slightly towards the roadway. The following trees and shrubs are amongst the most suitable and ornamental for planting in such situations, viz.—Arbutus, Portugal Laurels, Philadelphus, Anonhus, Coluteas, Spiræas, Berberis, Laurustinus, Cydonias, Tamarix, Broom, Phillyreas, Deutzias, Weigelas, Cornus, Eonymus, Chinese and Japanese Privets, Ribes, double Furze, Yuccas, Hypericums, Garryas, Lilacs, Hollies, and Sumachs. Should space be found amongst the foregoing somewhat in the background, the following trees should be introduced, viz., Birch, *Ascia*, double-blossomed Peaches and Cherries, Purple-leaved Beech, Laburnum, Cercis, Salix, Variegated Acers, Scarlet and other Horse Chestnuts, and Scarlet Thorns. Common Laurels, Ligustrum ovalifolium, and similar shrubs may be used to fill up any blanks which remain. Upon the broadest portions of the turf Pampas Grass, Yuccas, Bamboos, and any of the many graceful and dwarf-growing Conifers should be planted singly. Where Rhododendrons are planted in masses, the bulbs of hardy Liliums should be introduced amongst them. With respect to planting clumps, much will depend upon whether they will be in sight of the house or not, or whether they would be surrounded by any large forest trees, or otherwise; in the latter case our best forest trees would be the most suitable, whereas in the former I would recommend the following, viz., Maples, Birch, Catalpa, Liquidambar, Robinias, Chestnuts, Beech, Lombardy Poplar, Planes, Turkey Oaks, Limes, Ailants, Sycomores, Mountain Ash, &c. A few shrubs may also be mixed with good effect round the outer margin of such clumps.—CHARLES DENNIS, Southwark Park.

Hardy Ferns.—Kindly give me the names of four good British Ferns suitable for exhibition.—**W. C.** [*Athyrium Filix-femina* plumosum, *Polystichum angulare cristatum*, *Laetrea Filix-mas cristata*, and *Scolopendrium vulgare crispum*.—H. A.]

Tree Ferns.—I have some that appear to have a solid mass of roots yet, if reported in larger pots, the latter would appear disproportionately large. Would it injure them to cut off a portion round the root and replot in the same sized pot? Supposing it will not, what amount of root should be removed? The stems are from 2 ft. to 3 ft. in height, and in from 16 in. to 22 in. pots.—**AMATEUR.** [Is there any necessity for replotting your Ferns? We should be inclined to think not; they only require an abundant supply of water. If, however, you must cut away their roots to induce fresh ones to come in their places, you may reduce them one-half if you choose. Tree Ferns withstand with impunity a great deal of hard usage.—W. H. G.]

The White Poppy.—In answer to Mr. Masters (p. 132) allow me to say that the White Poppy is cultivated at Bodicots, near Banbury, by Mr. Rufus Usher, the well-known grower of medicinal plants. I saw it in splendid condition the summer before last in Mr. Usher's ground.—**J. K. JACKSON.**

A Cure for Wireworm.—I have some newly turned up meadow land which I wish to use as kitchen garden ground. As usual in meadow land there are wireworms, and the land is too heavy to roll. What is the next best cure? If rape dust, how, and in what quantities, should this remedy be applied?—**W. E.** [The land being too heavy to roll is unfortunate, but I would recommend the attempt being made as soon as the drying winds of March and April set in. In the meanwhile give the ground a good dressing of salt—say at the rate of 6 cwt. to the acre, and hoe or scarify as often as the state of the soil and other circumstances will permit. This operation will not only aid in the pulverisation of the soil but bring many of the worms to the surface, when the birds will soon find them out and devour them. I have tried powdered linseed cake on a small scale, and though it certainly destroyed some, it is a much more expensive remedy than salt and frequent rolling, which never fail to effect their destruction.—W. W.]

Names of Plants.—*G.*—*Myrsiphyllum asparagoides*. **W. C.**—We are unacquainted with any Asplenium bearing the name you give. Send us a frond or two. The correct spelling is *Imantophyllum*. **J. H. Ross.**—*Dendrobium aggregatum*. **W. C.**—*Laetrea spinulosa*.—*Subscriber*.—If the flowers are of a blackish-brown colour, and Violet scented, the plant is probably *Boronia megastigma*, which it appears to be, as far as we can judge by the scrap sent. **J. P.**—*Sparmannia africana*; send the other when in flower. **M.** *Regent's Park*—*Asplenium biforme*, syn. *A. bulbiferum incisum*.

Questions.

Finely-flowered Oncidium excavatum.—I have a small plant of this *Oncidium* in an 8-in. pot bearing a spike of bloom nearly 4 ft. in length, furnished with over 360 fully-expanded flowers. Is not that an uncommonly large number of flowers for this species to bear?—**AMATEUR.**

Heating Small Greenhouses.—I have a small greenhouse, span-roofed, 20 ft. by 14 ft., and 12 ft. high. I want to heat it to at least 50° or 55° during winter, but I am totally unable to decide what kind of boiler would be the best and ultimately cheapest, as each vendor declares his own apparatus to be the best, and I have no technical knowledge to enable me to estimate their respective merits. As this is a most important question to amateurs, would you kindly insert it? When I hope that some of your readers may be able to give us the benefit of their experience in the matter.—**L. J. BROWN.**

Cucumber and Melon Failures.—My Cucumber and Melon leaves have become spotted, and though the plants are growing luxuriantly and showing plenty of fruit, both that and the blossoms die off. To what cause can such failures be attributed?—**A. M.**

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

THE TEA-SCENTED ROSE.

(Concluded from page 154.)

Then will I raise aloft the milk-white Rose,
With whose sweet scent the air shall be perfumed.
Shakespeare.

Were I asked to name the Tea Rose (*a Tea Rose pur et simple*)—I will explain immediately upon which the proprietor might most confidently depend for the constant production of its flowers in true character, be the seasons propitious or unkind, I should declare to win with *Souvenir d'un Ami*. And this Rose is fair as she is faithful. Not only when grown under glass by such artists as Charles Turner and George Paul, 4 ft. in diameter, and covered with its large blushing blooms, is *Souvenir d'un Ami* a sight to make an old man young, but out in the garden, having a sheltered site and careful culture, it abounds in generosity and grace. Not only so, but in this, as in all other cases, the natural process, the purer air, and undiminished light, give a fullness and freshness which can never be quite realised by artificial means; and if a second question was put to me, "What Roses have most impressed you by the grandeur and size of their beauty, during your thirty-four years of observation," I must again reply, firstly, *Souvenir d'un Ami*, and secondly, a *Duc de Rohan*. The former appeared upon a most robust shoot, growing from a four-year old plant, upon a wall with an east aspect, and was, I think, the largest, heaviest, Rose I ever saw, or shall see. It was inspected by many gardeners on the tree, and was shown afterwards, cut, to others, all being unanimous in the opinion expressed by a rustic lover of the Rose, "My stars! she's a wopper! Some may read these lines who remember the magnificent specimens of *Souvenir d'un Ami*, which were shown at Hereford and elsewhere, by a brother whom we all love and mourn, the Rev. George Arkwright, and they will readily imagine the capabilities of an abnormal, highly-favoured bloom. The latter Rose referred to was a *Duc de Rohan*, shown by Mr. G. Paul, aforesaid, some years ago at Birmingham, so hugely handsome, that I entreated my friend to remove him from a box, in which he made all the other Roses to appear as though they were ashamed of themselves, and would gladly hide their diminished heads. They might have adapted and addressed to their owner Cassius' words on *Cæsar*—

Why, George, he doth bestride this narrow box
Like a Colossus; and we petty blooms
Blink under his huge leaves, and peep about
To find ourselves dishonourable graves.

* * * * *
Now, in the name of all the gods at once,
Upon what meat doth this *De Rohan* feed
That he is grown so great?

The last Rose on my list is not even noticed in many of our catalogues, and was unknown to me until my friend, Mr. Curtis, of Chatteris (*nulli secundus*, in his appreciation of a Rose), kindly sent me buds, from which I have grown and shown in victorious stands, the charming flower, truly named *Unique*. It is a white Rose, streaked with rosy-purple, *ressemblant à une Tulipe*, and is a most distinct and attractive variety. Unhappily the buds arrived when I had no vacancies on my seedling Briers, and they were of necessity inserted upon standards. Woe to me! the Rose is *Unique* no more, but has gone over to the majority of Tea Roses upon standards, and is dead. Although "there is life in the old dog (Rose) yet," on which these Tea Roses once bloomed in beauty, there are very faint signs of vitality in their illustrious guests; the sweet little cherubs perched up aloft are hopelessly frozen at the mast-head. It is sad to see them, after so much abun-

dant beauty, withered and blackened (the snowy *Niphetos* blackest of all, a swift and just retribution, some will say, upon my disparagement of her merits), and it is a welcome solace to transfer our tearful eyes to the Tea-scented Roses upon the seedling Briers, which are frost bitten, but not vitally injured "scotched, not killed," and from which we confidently anticipate a strong growth and bountiful efflorescence "when the green leaves come again."

I have written so discursively, in the enjoyment of my holiday among the Roses, as a horse, brought from stable to pasture, gallops hither and thither, *tota per arva ruit*, as we had it in our school pentameter, that I have left myself brief space to treat of those varieties of the Tea-scented Rose which are so luxuriant in their growth and "robust" in habit that they more resemble the *Noisette* than the Tea, reminding us of the wood and foliage of Cloth of Gold, Lamarque, and Sol-faterre. Regarding these climbing Teas in alphabetical order, we must off with our hats in the presence of the Belle, sometimes called the Glory, of Bordeaux, and of the Beauty of Lyon; but not even the gallant Captain Macheath would say, "How happy could I be with either," because though the pride of the Claret Capital has her charms, in amplitude of form, in glossy foliage, in bicoloured petals, which are of a fresh flesh colour on the one side and of a rosy-purple on the other, her Roses are rough in outline, and, in their quality, coarse. Had she been a Vine she would have produced good *vin ordinaire*, and plenty of it, but never *Lafitte* (by the way, I remember to have given half-a-guinea for H. P. Jacques Lafitte, but he was only a mediocre Medoc), never Latour, nor Léoville, nor La Rose; whereas the Lady of Lyons, the very name endears her to our gardeners, for was she not Claude Melnotte's, the gardener's, love? has much more elegance and refinement in contour and complexion. She is not, it is true, so beautiful nor so constant as Pauline Deschappelles; she has not quite the hardy constitution of her mother, Gloire de Dijon, of whom anon, but, in her best form, she is very winsome, with her pure pale lemon flowers; and thus La Belle Lyonnaise justifies the description of her fellow citizen:—*Fleur grande, pleine, bien faite, jaune canari foncé passant au saumon, très vigoureuse et très belle*.

Nevertheless, our Beauty of Cheshunt surpasses both these foreign belles, as completely as Venus surpassed Juno and Minerva. Her cruel father has selected for her the ugliest name he could find—Cheshunt Hybrid; he long evinced a reticence with regard to her merits, marvellously rare among the raisers of Roses; and some Rosarians who had planted the Rose, among them one of the most accomplished, have failed from defect of soil or culture to realise her charms, and therefore have doubted and denied them; but she has triumphed at home and abroad. The stern parent says in last report, "We think more and more highly of her after our yearly greater experience," and no Rose-grower who has seen her in the bloom of health, would think his garden complete without her. In pots, on walls, budded high or low, on Brier or Manetti, it is always charming, with its bright clean wood, and glossy leaves, and exquisite buds, and large symmetrical densely-petalled blooms, in colour rose, deeply flushed with carmine. It is a distinct novelty, and will, I hope, be the founder of a new family; in fact it already stands at the head of a *Nouvelle Série de Roses*—*Rosiers, Hybrides de Thés Remontants* in one of the French catalogues, followed by La France and two new Roses, sent out last spring by M. Guillot, Madame Alexandre-Bernaix, and Mademoiselle Blanche Durrschmidt.

Climbing *Devoniensis* is a very valuable variety, and must be one of our mural Roses, however few they may be, and however many the disappointments must be. I warn the young amateur of these disappointments, because the growth of this Rose is so rapid and continuous, that its wood is rarely ripened when winter comes, and it suffers grievously from the frost in consequence. Budded low on the seedling Brier, and well mulched early in December, it cannot be destroyed, and will come in strength from its base when spring returns; but this constant process of recovery and exuberant produce of branches, which are rarely matured, prevents as a rule that abundance of Roses which would be given to a more genial climate. A few

beautiful blooms we are sure to have, and with these we may well be content.

If to the tree some venial errors fall,
Look at the Rose, and you'll forget them all.

Of such an old and universal favourite as Gloire de Dijon it is superfluous to speak. The readers of THE GARDEN know as well as I that it is the first and the last, and the most generous, with its large, many-coloured flowers (white, buff, yellow, and red in lovely combinations), and that although it has rarely in its individual blooms that perfection of form which satisfies the keen connoisseur, no Rose, no flower, in our generation has shed so much beauty and sweetness around our English homes.

Gloire de Dijon has four daughters, Madame Bérard, Madame Levet, Mademoiselle Marie Berton, and Madame Trifle. The first of the four is smaller in size but more compact in shape than her mamma—a very attractive Rose; the second resembles the mother in vigorous growth, but is, in all other points, inferior; the others I have not proved. Madame Trifle is suggestive of something very sweet, though the French description of the Rose is more appropriate to the savoury, and sounds as though the writer was thinking of a mayonnaise—*jaune saumon à l'intérieur, parfois jaune d'œuf cuivé*.

And now ring out wild bells, roar cannons, bray trumpets, roll drums, float flags, fill balconies, wave handkerchiefs, and shout, my Rosarians, shout!—(Yea, let your shouting be such as hath not been heard in England since the Oxford Seven beat the Cambridge Eight at Henley in 1843)—for behold the Emperor of all (Tea-scented) China, Le Roi des Roses, the Field-marshal of the Universe! behold, in all his golden glory,

MARÉCHAL NIEL!

There are but three words which we dare to speak in such a presence as this—"Hip, hip, hurrah!" The hips, of course, for the seedling Brier on which he is enthroned, and the hurrah for the Royal Rose!

S. REYNOLDS HOLE.

THE INDOOR GARDEN.

PLANTING OUT WINTER-FLOWERING PLANTS DURING SUMMER.

I do not wish to find fault with those who adopt and recommend growing such plants as the berry-bearing Solanums, Salvias, Stevias, Eupatoriums, Libonias, &c., in pots all the summer, as I have no doubt success may be obtained in that way, but, according to my opinion, at a greater cost for labour, &c., than when they are planted out. Part of the success of planting such plants as those above mentioned in the open air in summer, depends upon the site selected for them. If planted in very rich land they are apt to become gross, and, therefore, do not lift well in autumn; often they lose their lower leaves, and do not flower so freely afterwards. Again, if the pinching or stopping of the growing shoots be neglected, a straggling habit is engendered, which is difficult afterwards to put right. The pinching should be done when the removal of just the terminal bud will suffice to give the requisite bushy habit. If delayed until several inches of wood have to be pinched off, there is a waste of power, as a greater check than is necessary is given, and in our short summers, time lost is never recovered. Assuming that an open-air, sunny position, where the ground has been some time previously well worked, is available, and that the plants intended to be put out are brought forward and regularly hardened off, about the end of May is a suitable time to plant. In allotting space to each species, the size which they are likely to reach should be considered, as it is better to have a few well-grown plants than a greater number of starveling, ill-developed ones.

Where only medium or small-sized plants are required, cuttings struck early in the season—say now—will, under good management, make good specimens, but when large plants for conservatory decoration are desired, then one, two, or even three-year-old plants, of some kinds, will be more suitable. If any of these be cut well back when the flowering is over, or

say about April, and planted out about the end of May or beginning of June, they will make handsome, well-furnished bushes for the following winter. It will be very beneficial to mulch the surface of the ground amongst and around the plants as soon as they are planted. Mulching tends to keep the roots close at home and near the surface, which will be found to be of immense advantage to them when the time comes for lifting and potting them, as the less the roots are cut about then the better; and for the same reason, in very dry, hot weather, water should be given when necessary, but if well mulched water will not often be required. The period for lifting may vary a little, according to situation, but in most places the middle of September will be as late as they should remain in the beds, and about ten days previous to lifting, the roots should be cut round with a spade at varying distances from the stem, according to the size of the plant and the size of pot they are to occupy, leaving as much root as possible.

If the plants are growing in rich soil, and at any time show symptoms of grossness, a spade thrust into the ground at a suitable distance from the stem, so as to sever some of the roots, will correct any tendency to a plethoric habit, and ensure the production of wood which will be fertile as regards blossoms. This plan of checking the roots a little with the spade will not take up much time, and may be resorted to when necessary, during the growing season. It will promote a larger root development close at home, which will be found to be of great benefit when the plants are lifted. After they are potted into suitable-sized pots (which should not be too large) they should be placed in a shady position for a few days, still keeping them in the open air, as the longer they can remain in the open air, if safe from frost, the better, as it will enable them to become well established before being housed; and they will be less likely to lose foliage than if lifted and moved into a drier, warmer atmosphere at once, before the roots had fairly recovered their power of supplying the wants of the plants. The advantages of planting out are at least twofold; it saves labour, and secures a better development if fairly carried out. Neither a very rich soil nor yet a poor one is so good as one of medium quality. Where the soil is poor and sandy, a little better soil should be placed round the roots of the plants when turned out.

E. HOBDAY.

COMMON PINKS FOR FORCING.

ANNE BOLEYN and the common white are desirable Pinks for forcing in quantity for cut flowers. In the preparation of the plants for forcing an early start is half the battle, and, to obtain this early start, the cuttings or pipings must be taken from plants that have been forced; and any one who may wish to make a beginning should take up a few plants as soon as the weather breaks, pot them, and introduce them by-and-by into a gentle warmth. The cuttings should be taken as soon as the new growth is in a fit condition for striking, which is when the young shoots begin to acquire just a little solidity or firmness at the base. They must be inserted under a handlight or in a close frame, where just a little bottom heat can be had. The cuttings must not be permitted to lie about exposed to the air whilst being prepared, as they are more susceptible of injury from this cause than most plants. As they are trimmed they should be placed in a pan or some other vessel containing water, till a sufficient number be prepared. If only a few are required, they may be rooted in pots or pans; but the first-named plan is the best, and produces the most vigorous plants. They must be shaded from bright sunshine and kept in a moist condition, without too much saturation. A light sprinkling of water when the shading is removed on bright afternoons will be beneficial. Under such conditions the cuttings will soon root, when air should be given, gradually increasing its quantity till fully exposed. As soon as they are sufficiently hardened to bear full exposure, take them up carefully and plant them out in a prepared bed in an open situation, about 9 in. apart. A fresh loamy soil, slightly enriched with old cow manure, suits them best. The summer management, which will not involve much trouble, consists in maintaining a loose friable surface by frequent stirring, and watering occasionally in dry weather. Early in October the plants must be carefully lifted, with balls and all the root possible, and potted in 5 in. or 6 in. pots, putting the strongest in the larger size. Some of the strongest plants of Anne Boleyn may perhaps require pots a size larger, if the cuttings were obtained early. After potting the plants may remain in the open air on a coal-ash bed for a time, but must not be exposed to severe frost. From the open air they

should be taken to a cold pit, where they must remain till moved into heat for forcing. The stronger and better established the plants, the better they will bloom when forced. But if started early, the forcing should begin gently, and the plants should occupy a light position. Of late years a class of perpetual or forcing Pinks has sprung up. About a dozen years ago a bright self-coloured kind, called Garibaldi, was largely grown in the neighbourhood of Yarmouth and Norwich, and among newer introductions the following are desirable kinds to grow for flowering: Annie Williams, White, Perfection, Miss Joliffe, Lord Lyons, Newmarket, and Lady Blanche. E. H.

SOPHERONITIS GRANDIFLORA ON CORK.

THIS, one of the most brilliant of winter flowering Orchids, is more amenable to different ways of culture than most plants. It may be grown and flowered successfully in pots, pans, or baskets, and we have frequently seen it planted on dead stumps of Tree Ferns, and with excellent results. Perhaps in no way, however, is it seen to better advantage than on arch-shaped pieces of virgin cork, as shown in the annexed woodcut, prepared from a plant thus situated in Messrs. Veitch's nursery, Chelsea, where a large number of plants of it are grown in this as well as in other ways. When on cork they can be suspended from the roof or placed flatways against walls or pillars, and in this way they can be grown without taking up space, which

Sopheronitis grandiflora on Cork.

would be available for other plants. Small plants of it well rooted should be obtained and fastened on the cork 2 in. or 3 in. apart by means of wire; they should then be suspended close to the glass in an intermediate house, kept well watered with the syringe during the growing period, when they will soon increase in size and occupy the whole block, and when covered with flowers in such profusion as the plant from which our figure was taken will form one of the most attractive objects in the greenhouse or conservatory during the winter months. Its blooms last, if kept free from damp, for a long time in good condition both on the plants and in a cut state, in which way they are unsurpassed for use in button hole bouquets. C. W. S.

DOUBLE-FLOWERED SEEDLING PETUNIAS.

FINDING these so exceedingly useful during the greater part of last summer and autumn for greenhouse and conservatory decoration, as well as for bedding purposes, I would strongly recommend anyone having such structures to keep gay, to get a packet of seed of the double varieties, and sow it at once; double kinds being best adapted for pot culture and not so suitable for turning out, their flowers being too heavy to withstand the effect of wind and wet, which, towards the end of the season, sadly mar their beauty. By sowing thus early, plants may be grown to a large size and had in full bloom by July, if nursed on for a time in gentle heat, and then placed in cold frames or a light house where they can get plenty of sun. This renders them short-jointed, and much more floriferous than they otherwise would be, as the least shade draws them up

weakly, and makes their branches so puny as to require support. The best I had were plunged out of doors in a bed of ashes to keep the pots cool, and thus prevent the soil drying too rapidly. This kind of treatment appeared to suit their requirements exactly, as they grew close and dense, a condition aided by having the points of the shoots nipped out just before the plants received a shift into larger pots.

Although double Petunias may be propagated by means of cuttings, seedlings are preferable, as they grow stronger and give little trouble, but when any of very superior merit show themselves it is always worth while keeping a stock plant of such for cuttings, which, put in now, soon strike root on a manure bed under a bell glass kept close for a time. The single forms make grand beds if planted where they can have plenty of room to spread, but, as they are naturally strong growers, a poor soil is best for them; if deep, so that the roots can get well down, that checks any tendency to over robustness, and yet affords the necessary support during dry weather. Besides forming magnificent beds, single Petunias make fine masses in borders, but, when used in that way, they require support; the neatest and best way of effecting this is using coarse-meshed rabbit wire cut into yard lengths, which, run round and tied to a stake at the ends, forms a capital frame, through which they thread their shoots, and completely hide the wire with their gay blossoms and foliage. There are many other plants of a similar character for which a trellis made in this way answers well, and, as they last for years, nothing for the purpose can be cheaper or more handy.

As Petunia seeds are very small, they should only be slightly covered at the time of sowing, otherwise the young plants are unable to push through the soil. Pans for such seeds should be filled nearly full with rough leaf mould, and on the top of that should be put an inch or so of finely sifted soil made perfectly level and smooth. That done, the next thing is to give a gentle watering, and then they should not be disturbed for a few hours, when all will be ready for sowing. This should be done thinly, and a little silver-sand sprinkled over the seeds, when, if placed in a moist heat, they will soon germinate, especially if the pan be covered with a sheet of glass, or kept dark by a piece of paper for two or three days, as by that means evaporation is intercepted and a more uniform warmth is maintained. S. D.

ORIGIN OF THE SPOTTED GLOXINIAS.

THE origin of this strain of Gloxinias is interesting, as it affords an illustration of how flowering plants which reproduce themselves freely from seed, sometimes break into new and distinct types of form and colour. It has frequently occurred that a certain family or species, which may not have shown during a series of years any great tendency to sport, all at once gives us something both novel and beautiful. M. Vallerand, with whom these spotted Gloxinias originated, informed me that for a number of years he assiduously crossed the best known varieties, but, although he annually raised a large number of seedlings, he could not succeed in obtaining anything better than those already in cultivation. Being discouraged at finding his best efforts so poorly rewarded, he had determined to relinquish the attempt. His seedlings that season had nearly all bloomed, with the usual result. There remained but a few weak plants to flower. Curiously enough, on the weakened and latest seedling appeared a single flower, so distinct and so beautifully marked, that M. Vallerand declared that he was quite taken by surprise. If I remember rightly there was but a single bloom on the plant. It may easily be imagined how that plant was cherished, the flower carefully fertilised, and precaution taken to destroy every other bloom near it. The seed was ripened, and from this sprang many other charming forms. All M. Vallerand's varieties were distinguished by a neat, compact, floriferous habit, and the curiously mottled flowers, so unlike the ordinary strains of Gloxinias, caused at that time quite a sensation in the horticultural world. I have a vivid recollection of going to see his seedling plants when coming into flower. They were planted out in ordinary frames, and certainly presented one of the most interesting flower displays I ever witnessed. All who grow Gloxinias should have some of these spotted varieties in their collection, for, as may be seen by the coloured plate given in THE GARDEN of last week, they are not only highly ornamental, but have a peculiarly chaste and delicate appearance.

Byfleet.

J. CORNHILL.

Treatment of Cyclamens After Flowering.—My experience differs from that of Mr. Cornhill (p. 164) in one very important particular, and as I am a successful grower it is worth consideration. Instead of placing the bulbs to rest under a north wall or frame I place mine where they can get all the sun possible, covering them slightly with leaf mould. A traveller in Palestine told me of this as being natural to the Cyclamen, and I believe the more sunshine it absorbs in this stage of growth the more flowers and the finer will it have in the future. —BROCKHAUST.

Ferns in Windows.—I have an arch over a window in my conservatory fitted with cork, between which are planted different kinds of Ferns. I find great difficulty in supplying the roots of these plants with sufficient nourishment, as the syringe only waters the fronds and leaves the soil almost untouched. Besides I find the syringe spoils the foliage of several kinds, such as *Adiantums*, some sorts of *Pteris*, and others, while on the other hand the spray suits the *Davallia canariensis* and *Platynerium alcicornum*. Can any of your readers recommend any contrivance which would enable the water to drip and percolate gently amongst the pieces of cork, and thus supply water to the roots. —M. L. D.

Heating Small Greenhouses.—In reply to Mr. Browne's inquiries (p. 172), allow me to say that I have a house of about the same cubic contents as the one he mentioned, for which I use a boiler of the following construction. It consists of about 25 ft. of 1 in. steam pipe bent into a series of coils, each coil being 15 in. in diameter, with a space of 1 in. between the coils. The top and bottom ends of the coil are turned outwards opposite ways, and, passing through the brickwork, serve to support the coil. The whole is set in a square fire brick chamber one brick thick, and the chamber is carried up 1 ft. 6 in. above the top of the coil to form a hopper, which is charged with coke. The flue is carried out just level with the top of the coil, and, as the fire below that point burns out, fresh coke falls down to supply the waste. Wrought iron pipe 1½ in. in diameter is used for the connection between the inlet and the outlet of the coil and the cast iron pipe in the house, consisting of 98 ft. of pipe 3 in. in the bore. I have two of these boilers at work, and find no difficulty in maintaining a constant temperature of 55° in one house and 65° in the other. In fact, the temperature has never fallen below these points during the present exceptionally severe winter. The fire only requires attention once in twelve hours, and the average cost per day is 3d. If your correspondent will write to me I shall be very pleased to send him a drawing of the coil and mode of setting, together with other particulars. —J. A. OXLEY, *Inver Hill, Frome*.

Rustic Baskets.—To those who appreciate a really pretty rustic basket, allow me to recommend Wyth Elm rods for their manufacture. The bark being thick, wrinkled, and deeply serrated, resembles that known as virgin cork on a reduced scale without being so heavy in appearance. The heart of the rod is tough, and the bark never seems to have a tendency to crack or peel off even when exposed to a temperature under glass of from 80° to 100°, i.e. when the baskets of which it is made are used to hold plants in pots. I have not tested them with loose soil, but have no doubt of their proving satisfactory. The rods can be obtained of wattled fence or common hurdle makers, and are very cheap. One rod of say from 8 ft. to 10 ft. in length, and from 1 in. to 2 in. thick, on an average, will make a basket quite large enough to hold a fair-sized pot. If required, such rods can be delivered split up the middle. Nothing more is wanted for making up such baskets, but some small galvanised or copper wire, and they stand a vast amount of tear and wear. —C. F., *Merrivood*.

Plant Culture without Bottom Heat.—Mr. Simpson's admission (p. 139) that he never plunges plants of any kind in a bed heated by pipes or fermenting materials, that is, does not use bottom heat, at once brings the discussion between us on this subject to an end. If Mr. Simpson had read my article carefully, he would have seen that the figures given by me clearly referred to the temperature of the house, not to that of the plunging material. It is self-evident that plants grown in hothouses in pots or similar appliances, cannot fail to have their roots as warm as their tops. It is opposed to both the nature and the well-being of plants, to subject their roots to greater heat than their tops, by plunging them in material with a higher mean temperature than that of the air of the house in which they are grown; when less than this is used, from a common-sense point of view there may be said to be no bottom heat at all; and going beyond the subject as relating to plants, with their roots as well as their tops confined to the houses in which they are grown, there is abundant irrefutable evidence that they do as well, or better, with the roots cooler than the tops. But setting individual opinions aside, the fact remains that the greater portion of the best and most successful plant growers have ceased, or all but ceased, to use bottom heat. —T. BAINES. [We have published the above at Mr. Baines' particular request, but here this discussion really must end.]

TREES, SHRUBS, & WOODLANDS.

"TREES OF THE FUTURE."

The family of Spruce Firs, including both *Picea* and *Abies*, may fairly be considered as the type of a Fir tree. Differing as it does by its upright spiry growth and tiers of horizontally spreading side branches, from the rounded forms and spreading, branched head of deciduous trees, we owe to this family in particular much of the charm which our varied woodlands afford us. In the future it seems most probable that the modern introductions will exceed in beauty anything which we before possessed, and will, owing to their hardness and adaptability to most soils and situations, increase the favour in which they are already held. It is again to California, or Oregon, which borders on it to the north, that we are indebted for the most beautiful and hardy species. First, both by right of beauty, as well as by alphabetical precedence comes *Abies Albertiana*, a tree that has now been introduced long enough to show that it is capable of coming to perfection in this climate. It has not received half the attention which it deserves, because it is so much like the Hemlock Spruce (*Abies canadensis*), which does not usually thrive in this country from reasons that are difficult to explain, and is at best but a rather small tree. *Abies Albertiana*, in the forests of Oregon, is a large and most graceful tree, attaining a height of 120 ft. in most places, and exceeding that height occasionally; so far surpasses *A. canadensis* in stature, while it closely resembles it in habit. Its soft, drooping branches and delicate feathery sprays of foliage, silvered over on the under side, coupled with great rapidity of growth in ordinary soils and situations, should make it a formidable rival to the Deodar, as a graceful tree to be looked at on a lawn at all seasons of the year, and its hardness, combined with its beauty, makes it, perhaps, the most satisfactory tree of large growth introduced during the last twenty years. Side by side with it in its native Oregon forests grows the green *Abies Douglasi*, another tree that has shown itself thoroughly at home with us in England, and is justly considered a very valuable addition to our hardy trees. Its soft, green foliage, rapid growth, and abundant branches have made it very popular among planters, and, as it is a tree of the largest size, we may confidently hope that the next generation will see many thriving examples of it towering aloft and forming landmarks in the distant horizon.

The somewhat sombre but still beautiful *Abies nobilis*, with its dark colouring and stiffer growth, is another most distinct tree from this region, the climate of which in the main so much resembles our own; owing to its sturdier growth it suffers less in exposed situations than *A. Douglasi*, whose only fault is that it loses much of its beauty when fully exposed to gales. In common with these other introductions from Oregon, *A. nobilis* is endowed with a vigorous constitution, and thrives equally well on the flat plain as on the hillside. The fine specimens of this Fir at Elvaston Castle are among those earliest planted in England, and, even in that somewhat low and flat situation, they have withstood the most trying frosts. Perhaps no family of Conifers can show three such distinct and beautiful species as these, the growth and colouring of which are so varied: the first, *A. Albertiana*, with slender branches and short, flattened leaves that spread only horizontally, and show but little of their silver lining; the second, *A. Douglasi*, whose leaves are bright green, soft, and long, radiating like a brush through three parts of a circle; and, thirdly, *A. nobilis*, with stiff blue-green leaves that curve upwards, and which, when young, tip the branches with silver by showing their under surface—thus giving a special beauty to this tree in the month of June.

In so large a family there must be degrees of beauty among its members, and *Abies nigra* certainly has the least claim to that gift in its native country. A small tree even under the most favourable circumstances, it becomes, after forty years' growth, the most wretched-looking object conceivable, with scanty branches and a blackened, smoke-dried aspect. It is the presentment of misery itself, and gives a chill, northern look to its surroundings that can hardly recommend it generally, but yet it has been planted in many parts of the country because there is a stage of its growth when it is attractive; as that, however, soon vanishes, it only deserves mention as an

ornamental tree to be avoided, unless a specially wintry effect be sought for. To Russia it is that we owe the hardy and beautiful *Abies Nordmanniana*, a Conifer that has been largely planted during the last twenty years. In a young state it is decidedly greener and more ornamental than the familiar Silver Fir (*A. Picea*), but in after life it much resembles it. Never attaining to the lofty height of its Alpine congener, it is, nevertheless, a valuable tree, as it is less exacting as to depth of soil and sheltered situation, conditions required by a Silver Fir if mature beauty be sought for.

Among so many introductions from far countries it is pleasant to find an European species (*Abies* or *Picea Pinsapo*) so thoroughly at home in English gardens. A native of Spain, and rejoicing in limestone soils, it has replaced in many localities, its earlier introduced congener *Abies cephalonica*, which, in Nature, is confined to the small area of the island from which it takes its name. Just as *Abies Albertiana* is superior to *A. canadensis*, so is *A. Pinsapo* superior to *A. cephalonica*, a vigorous form of the same Conifer, which adapts itself to circumstances, and forms a handsome and distinct tree. Its rigid, hedgehog-like leaves that radiate evenly round the young shoots, and the spray that branches at right angles to the side shoots, distinguish it at a glance from any other kind; indeed, on the whole, it may be considered the best of European Firs from an ornamental point of view. The Himalayan Spruce Fir (*Abies Morinda*) is another distinct member of this family that must not be overlooked in reference to future blame or praise, and there can be little doubt of its gaining a favourable verdict when planted rather closely. Like the Deodar, its side branches hang very closely to the main stem; the small spray droops perpendicularly as a Weeping Willow, and the whole tree assumes quite a columnar aspect in consequence, so that it has somewhat of a drawn-up look. Owing to its superior hardiness, compared with the Deodar, it reproduces its natural growth in England, and promises to attain something like the height which it reaches in its native country.

Before closing these imperfect notes, which only touch on some of the most familiar of modern importations, a few words on the Japanese *Retinosporas* may not be out of place, as they have lately been so much planted in all parts of the kingdom. In their native country they are of a very straggling habit, so much so that unless pruning or tying up be resorted to, they are apt to become quite unsightly. The lovely *R. plumosa* is a particular instance of this, and the most beautiful specimens in Japan were to be seen in the courtyards of temples, where they were trained to a single stem, and the side branches dexterously pruned, till the effect was much like that of a green fountain. In the colder climate of this country it becomes less straggling in habit, and we are thereby the gainers. *R. obtusa* and *R. pisifera*, though less beautiful, are satisfactory small-growing Conifers that have each a charm of their own, but the variegated forms have a singularly mealy, unsatisfactory effect when full grown. In Japanese gardens it is usual to associate the brightly-coloured Maples with these green Conifers, and it is only under such conditions that the gold variegated variety is seen to any advantage, while the silver variety does not make a really good effect, even under such favourable circumstances. English cultivators now have such numbers of beautiful trees and shrubs from which to select that they can well afford to reject some things that have little else than novelty for their recommendation and may, by planting only what is proved to be beautiful, render their gardens the pride of the world.

E. H. WOODALL.

IMPROVING SPRUCE FIRS BY CUTTING OFF THEIR TOPS.

WHILST the subject of Coniferous trees is being discussed, allow me to recommend those of your readers who wish to have ornamental specimens of the Spruce Fir to try the effect of cutting off the tops of those whose upward growth is so rapid as to prevent their being well-furnished with side branches. The late Mr. Pearson, of Chilwell, first gave me this advice about twelve years ago, telling me of a gentleman who then lived in the south of Nottinghamshire, who had for a long time been in the habit of treating his Spruce Firs in this way, and with good results. Mr. Pearson also illustrated his advice by two specimens of *Abies Nordmanniana* on his lawn, one of which,

the handsomer and better furnished tree of the two, had formerly been cut down for mischief by one of his children to about half its height. The same thing had recently happened to one of several plants of *Nordmannianas* which I had planted here, and that tree is now the best I have out of some hundred. I do not recommend, nor are any of your readers likely to adopt, an indiscriminate beheading of such trees, but if those who have several specimens of the same sort will try the effect on some of the more lanky and fast growing, I feel sure they will not be disappointed. I have found the treatment answer well with *Abies excelsa* and *A. Nordmanniana*, but especially with *Abies Douglasii*, a species very apt in some soils to overgrow itself and very ready at making fresh leaders. It is interesting to watch the process by which the end of a side branch is educated into a leader, the branch being gradually lifted by it into the perpendicular line of the trunk, when the point of section gradually disappears. I have just cut off 8 ft., being about one-third of their height, from two of my tallest trees of *A. Douglasii*, planted about ten years ago, and through my experience of the treatment have more confidence of the result than some of your readers may feel. I have not treated any specimens of *Abies nobilis* in this way; that species is rather shy as regards making a new leader, and I am hardly rich enough in it to make the experiment.

Edge Hall, Malpas.

C. WOLLEY DON.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS

Pruning Euonymuses.—There are few shrubs that are better adapted for edging beds or planting on sloping banks or margins of shrubberies than Euonymuses, but the beautifully variegated gold and silver leaved varieties need constant watchfulness in regard to pruning away the green-leaved portions, or the latter quickly monopolise the strength of the plant, and the variegated shoots languish and eventually become overpowered. As, however, a tolerably large collection may be looked over in a short time and the plain-leaved shoots removed, neglect in reference to this matter is inexcusable. As Euonymuses are easily raised from cuttings inserted under hand or bell glasses, I need scarcely say that it is important that the best coloured shoots should be selected for cuttings. Few plants are better adapted for pot culture than Euonymuses, and in districts where this beautiful shrub suffers from exposure a portion at least of the stock should be grown in pots so as to receive some protection in winter. A rather poor compost is the best for bringing out the leaf colouring of the variegated varieties.—J. GROOK.

Camellias Out-of-doors.—I have seen these grown out-of-doors in many different localities, but the most healthy bushes I have ever seen were grown in a border behind a north wall amongst Rhododendrons in Scotland. Owing to the position, or probably the latitude of the place, they did not flower; but they were not injured by 27° of frost in the severe winter of 1860. We have a few plants at Loxford that grow well and also flower well in mild seasons. This year they were well furnished with flower buds, which look well even now, but on taking hold of them they drop off, owing, no doubt, to the severity of the winter. The lowest temperature registered here has been 20° of frost. I see it is stated by some that the buds on bushes out-of-doors are all right. Have they been put to the test of shaking the bushes, or trying to pull them off with the hand?—J. DOUGLAS, Loxford Hall, Lf.ord.

—We have grown Camellias out-of-doors here for more than forty years. An old workman says that one of our plants was a large one 8 ft. or 10 ft. high forty years ago, and that it was protected throughout the winter with poles and mats. It stood near the house in a very sheltered nook. About eighteen years ago, in order to protect it more fully I had a movable framework made with upright pillars, which fitted into sockets let into the ground; from these rafters were fixed to the house, and a light trellis work on the top was covered with mats, which were also hung in the front to protect the plant as much as possible in severe weather. Now, although this was a very fine healthy Camellia in a sheltered place, and well cared for, setting its buds as freely as possible, often five and six at a point which were duly thinned, good flowers were the exception. They opened with a yellowish or brownish tinge at the base of the petals, and dropped almost as soon as they were open; in fact, the season of flowering was so short, and the quality of the blooms so inferior, that I boxed up the ball of the plant and, with lifting jacks, a strong truck, and horse power, removed it to the centre of the conservatory. It is now 12 ft. high, 15 ft. by 15 ft. through, and is furnished with several hundreds of flowers, in all stages of development; some, being open before Christmas, were used for church decoration. In the case of another plant of the same sort (double white) which has been protected and well sheltered, both plant and buds appear quite healthy,

but I am of opinion that not a single fairly good flower will be produced. When the buds are out through, they will be found to be dark in the centre. I would recommend no one who wishes for good flowers, to plant Camellias out of doors, unless in a milder climate even than that of Devon. That they are perfectly hardy, I admit. Some of the growths of last year are 9 in. long, and in good health, but no evergreen with which I am acquainted is more liable to be broken down by snow, and protecting them from that is the chief reason why we protect them here. Sorts of little value may be planted where a little protection can be given, but I would say all good sorts are well worth growing under glass.—JOHN GARLAND, *Killerton, Exeter.*

Camellias under a Verandah.—It may interest some to know that Camellias thrive and look well under a verandah. We have some doing remarkably well and full of healthy buds as large as small Nuts. They have protection from frost only.—WETHERDEN.

GARDENING IN RUSSIA.

From a letter kindly handed to us by Mr. Robert Marnock from an English correspondent of his residing in the Province of Poltava, we make the following extracts:—The snow is now (Jan. 10) so deep, and the weather so boisterous, that even the shops in our village are shut. But winter only began about the middle of December; till then we had beautiful weather. It sometimes happens, too, that we have very little or no snow all the winter, but with hard frost and no snow the roads are frightful; at other times we have neither frost nor snow till February or March; once I have seen spring begin very warm at the end of February, and in the middle of May there were eight days of frost and cold cutting wind; but, in general, winter begins about November and lasts till the middle of March. Worst of all, in this part of the country, the summer is sometimes terribly dry, not a drop of rain falling during two and even three months; this happens every five or six years, and, when you consider the great heat of this climate, you may imagine what are the effects of such long, dry weather. However, the Province of Poltava is not so dry in general as some others further south in the direction of the Black Sea, where there is so little rain sometimes—as last year, for instance—that the crops never arrive at maturity. They are, besides, exposed to the depredations of enormous locusts that swarm in those parts and fly about like birds. They are very pretty but very destructive. A young man who called on me in Kieff last autumn said that last year his father's estate, nearly 3,000 acres, would not yield 100 roubles (£10). In that part of the country, too, the crops are destroyed by an animal called *avashka*; it is about the size of a rat, and lives in holes underground, and, indeed, the ground seems to be full of it everywhere.

In this part of the world it is impossible to have early crops of Cucumbers in frames, unless these are made to fit closely, owing to mice. The Russians are particularly fond of Cucumbers, and must have them at any price as soon as possible. It seems that even the mice, too, have aristocratic tastes, as they prefer them to anything else, especially the seed, which they are certain to scrape up and eat, if they can only get into the frame. About 400 fruit trees had grown here for seven or eight years on a hill, where they were continually beaten and battered with the wind. Of course, they did not yield a bushel of fruit a year. I have had them all lifted and planted in a charming valley, where the soil, too, is much better, and I am in great hopes that we shall have heavy crops this year. We have but few stone and greenhouse plants, for the fact is we have not a suitable place in which to keep them; but we have a great many bedding plants for the *parterres* near the house. In this part of the country it is not men but girls or women that are employed generally in gardens, sometimes only little children. Men are too scarce everywhere, or too dear, and all are required for the field; even boys are sometimes not to be had. In general, people are engaged for the whole summer, otherwise there would be nobody to do the work. Not only do the peasants know nothing about work in a garden (they can neither dig nor rake like a workman), but it is quite painful to see the dawdling sleepy manner in which they go about it. However, I can always have one or two men when I really need them, besides two which I have regularly, in the way of foremen to carry out the work.

There are a few things in Russian gardening which, by way of contrast, I may mention. For instance, it is only the roots of Parsley and Celery that are used in the kitchen; the leaves are never required. Celery is never earthed up and blanched for salad, as in England and other countries, because nobody would eat it. There seems not to be a single stone in the ground; at least, I have never seen one in the whole province of Poltava. The working hours are from sunrise to sunset, that is, from three or four o'clock in the morning till eight or nine at night. Girls are paid at the rate of 10 copeks

a day, women 15 copeks; at the very most, when digging is required, they receive 20 copeks, that is, about 61. a day, and it is considered very good pay. There are but few gardens in the far away steppes which are not entirely under the control of the stewards, so far as relates to the work-people and payment. They rarely have, however, unfortunately, either knowledge or taste, so far as relates to gardening, and when the owners spend their time and money in towns far off, or in other lands, of course, the gardens are allowed to run to waste. This has been the case in several places where I have been; still, I know of several gardens managed by gardeners with whom the steward has no dealings."

THE FLOWER GARDEN.

GYNERIUM JUBATUM.

This is a magnificent Grass, with a flowing, mane-like inflorescence. As the engraving shows, the lateral branches of the plume are remarkable for their length and their graceful curvature, and the secondary branchlets are numerous, long, and slender, the whole forming a dense, massive plume, not less than 3 ft. in length. I have only seen a female inflorescence, which is of a silvery hue slightly tinged with pink at the base of the separate florets. Perhaps it may be worth while stating that the sexes are borne on separate plants in all the species of *Gynerium*, and that the plumes of male flowers are neither so handsome nor so durable as the plumes of female flowers. Whether this is a distinct species the material before me is insufficient to determine, but its distinctness and superiority as a variety are beyond question. The specimen from which the accompanying woodcut was prepared was supplied by Mr. Gumbleton, in whose garden, at Belgrove, near Queens-town, it flowered last autumn. W. B. HEMSLEY.

Outdoor Verbenas.—Although the Verbena is seldom seen in good condition as a summer bedding plant, it is nevertheless well worthy of a little extra attention for that purpose, but good plants cannot be had except good cuttings are procurable. The best means of insuring these for spring propagation is to keep a few store plants in pots all the summer, cutting them pretty closely in the autumn and giving them a shift. Soon afterwards they should be set in a cool house or pit from which frost is excluded, and in this way better cuttings will be insured in spring than those from autumn-struck plants.—J. G. Linton.

Violet Culture for Market.—The statements referring to this matter quoted by "C. W. S." (p. 155) are too high. Violet culture furnishes to the grower no such an *El Dorado* as is there suggested. Violets are an uncertain crop, and only in good seasons can they be said to pay well. The writer puts the rental of ground as low as £4 per acre, instead of which good market garden land in the neighbourhood of London will fetch from £5 to £6, and the rates, of which no mention is made, are heavy. Whilst the Violets have been calculated at the highest prices the expenses have been put at the lowest; but labour and manure are very costly, especially the latter, as may be seen when I state that an ordinary cartload, as brought from London, is valued at 10s., and the picking, bunching, and marketing present a formidable item. It is difficult to follow the writer when he alludes to bonquets. Violets are gathered at so much per dozen bunches, and generally "leaved" by others, then tied into half-dozens, and in this way sent to market. All the calculations I have heard in relation to the Violet are based on the price per dozen bunches, which are sometimes as high as 2s. 6d., sometimes as low as 91., all depending on the season. During a mild open winter Violets will constantly expand a few blooms, and these maintain a small amount of trade, which is the best paying one; when towards the end of March and the beginning of April, the entire crop of bloom expands and is soon over, the price falls to its lowest point, and the soil produces nothing more for the next eight or nine months. Such a winter as the present is most disastrous for Violets, there being no blooms and the leaves are destroyed wholesale. When the crop does come it will be all at once, and with a glut the returns will be very low. An average profit of £20 to the acre is esteemed a very satisfactory one.—A. D.

Lily Bulbs.—In reply to "B." (p. 157) allow me to say that so far as I could see, the bulbs were the identical ones planted in April, for they occupied the same spots; and the nature of the position which they occupied, coupled with the totally undisturbed condition of the ground, quite precluded the possibility of any person having changed them.—T. SMITH, *Neury.*

A NEW PAMPAS GRASS (*GYNERIUM JUBATUM*).

ORNAMENTAL-LEAVED AND BERRY-BEARING PLANTS FOR MARKET.

PLANTS grown expressly for the beauty of their foliage are at all times in great demand, and many growers devote the greater part of their space to them. Ferns, Palms, Dracænas, and similar plants find a place in the flower market at all seasons of the year, and, as they last for a much longer time uninjured by exposure than flowering plants, as a rule, they fetch more regular prices, inasmuch as growers can take them back again and still grow them into larger and more valuable plants, whilst if flowering plants be not disposed of soon after they come into bloom they become comparatively of little value, and have to be sold for what they will fetch.

FERNS.—These constitute the most important fine-foliaged plants grown for market; they are cultivated both for sale in pots and for furnishing fronds for mixing with cut flowers. The kind most in demand is the Maiden-hair Fern (*Adiantum cuneatum*), and with this—so great a favourite is it—it would be difficult to overstock the market. It is of medium growth, and stands well in rooms when not subjected to the influence of gas-light. In is, in fact, everybody's Fern. It is increased by division of the roots and by spores or seeds, which are sown in September and October, in pots filled with light sandy soil. A little finely-sifted brickdust is generally placed on the surface of the pots, because it soaks up moisture, and prevents the plants, when making their appearance, from damping off, which they are very liable to do. The pots are plunged in beds in which there is a little heat, and they are covered with bell-glasses, small lights, or circular pieces of glass. When well established, they are pricked out thickly in small pots, and afterwards divided and potted on until they are in 5-in. or 6-in. pots, or larger as desired. All Ferns are increased and grown in the same way, excepting such kinds as British Maiden-hairs (*Adiantum Capillus-Veneris*), which have creeping rhizomes, and these are usually increased by cutting up old plants into small pieces and potting them at once in 5-in. pots. To furnishing green fronds of *Adiantum cuneatum* for cutting, a grower near Tottenham devotes several houses. The plants for this purpose are grown in 12-in. pots, in good peat loam and sand, and the fronds which they produce far surpass any which I have seen in any other establishment near London. When these large specimens become exhausted from constant cutting, they are pulled to pieces and potted into 8-in. pots, and are replaced by a batch which has been thus treated previously and become well-established in large pots. In this way a continuous succession of fine healthy plants is kept up. The house set apart for plants for the present cutting is kept much cooler than those in which they are being brought on in succession, and by this means the fronds become hardened, assume a deeper green colour, and last in good condition after being cut for a much longer period than if they had been subjected to a warmer temperature. Each large plant is expected to furnish sufficient fronds during the year to bring in 15s., the average price being 9d. per bunch of about a dozen fronds. *A. gracillimum*, which is a variety of *A. cuneatum*, is now becoming popular as a market plant, on account of its light and graceful fronds, which are excellent for bouquets. It seeds readily, comes true to character from spores, and is, therefore, a favourite with growers. A larger variety, named *A. concinnum latum*, has during late years been held in high estimation; and this has been so far fortunate for growers, as it can be raised to any extent by

means of spores, the produce of which in one year may be grown into beautiful specimens, well furnished with large and graceful, rosy-tinted fronds. A kind similar to this, but in some respects better, named *A. Flemingi*, is likely to be grown ere long to a considerable extent; as yet, however, it is scarce, and, in addition to its requiring more heat than other kinds, it is questionable if it can be raised in as large quantities in so short a time as would be desirable. Indeed, neither of the two kinds last named can be grown anywhere but in a warm house, and their fronds when exposed to the air soon become shrivelled up, both in a cut state and on the plants. *A. decorum*, an old variety not unlike *A. cuneatum*, still maintains its value as a market Fern. It is a fast grower, and an universal favourite. *A. scutum* is also a good variety, resembling, when well grown, the beautiful *A. Farleyense*, but it is much more easily grown, and it lasts long in perfection. With some growers *A. hispidulum* and *A. formosum* are favourites, and so are also the stronger-growing, broad-leaved kinds, such as *A. trapeziforme*, *macrophyllum*, and *Catherinæ*; in fact, most of the *Adiantums*, when grown into neat little specimens, soon command purchasers, but many of them are useless for cutting, and too slow growers to be remunerative. Next in importance to the Maiden-hair Ferns are the different kinds of *Pteris*, of which *P. serrulata* and *tremula* and their varieties are most in request. The common *Pteris serrulata* is a graceful little Fern, but it takes a long time to grow into a good specimen. The advantages belonging to it are that it can be grown in small pots, and, either in a cut state or on the plants, its fronds stand well for a long time, even when exposed to a cool temperature. Of this species there is also a variety in cultivation named *P. serrulata major*, which, when grown in 6-in. pots, is one of the most graceful of Ferns. It has fronds from 2 ft. to 3 ft. in length, branched and beautifully arched, so that a well-grown plant of it forms a grand object for room or table decoration. It is somewhat scarce, owing to the large demand for it and the difficulties experienced in raising it from spores. There is also a crested form of this Fern (*Pteris serrulata cristata*), which is very valuable for market purposes. It grows quite as freely as the original form, and is very pretty. As a pot plant, however, *Pteris tremula* is, perhaps, grown to a larger extent than any other belonging to the genus. It will stand for a long time in heated rooms, and excellent specimens of it can be obtained from seed in twelve months. A new kind of *Pteris* raised in Mr. Ley's nursery at Croydon, named *P. Leyi*, is one which will, no doubt, in time, be largely grown to supply fronds for cutting. As a pot plant, it is unsuitable for market; but its fronds, which resemble in shape a bird's claw, are valuable for placing at the back of button-hole bouquets. To the above kinds may be added *Pteris serrulata cristata grandiflora* (a handsome form), *Adiantum pubescens*, *Phlebodium aureum*, *Blechnum corcovadense* and *braziliense*, *Nephrolepis exaltata* (a useful kind for baskets, and very popular), and *Adiantum Farleyense*. Some of the *Gymnogrammas* are also much grown, but they are difficult to manage when in a small state during winter, and require, perhaps, too much attention to be as remunerative as some of the kinds above named. *Dicksonia antarctica* and some of the *Lomarias* and other forms of Tree Ferns make excellent market plants in a small state, and command a ready sale. They are easily raised from spores. Many other kinds of Ferns are also grown for market, but those just enumerated are the kinds principally cultivated for that purpose. Very large quantities

of the small-growing Ferns are sent to market in April in 2½-in. pots, and in this state they find a ready sale. *Adiantum Farleyense* is propagated by division of the plants, which are cut up in winter and spring. This fine Fern is marketed all through the year, and, owing to its fine appearance and its comparative scarcity, it always fetches good prices. Its fronds are of little value for cutting, as they wither in a few hours; but, as a table plant, this Fern is much sought after. As yet, it has not been raised from seed—a fact which is detrimental to its being propagated quickly, and hence the cause of its being sold at higher prices than most Ferns.

PALMS.—There is always a large demand for Palms in the market; therefore, at all seasons of the year, we find them liberally associated with flowering plants in the florists' shops. They are principally raised from imported seeds, sown in pots and pans, and placed in bottom-heat. When the young plants are up, they are pricked out in other pans or boxes, until they get again established, when they are potted off singly into 3-in. and 4-in. pots in good rich loam and peat. Plenty of heat and moisture are given them; as they progress, they are potted into 5-in. and 6-in. pots, and, before being sent to market, they are exposed to a cooler temperature, in order to harden them a little. Some are potted in large pots, but the pots generally used are 6-in. ones, and in these large and healthy plants are grown. Among the best and most appreciated market Palms is *Livistona borbónica*, a kind easily raised from seed, and one which grows rapidly, good saleable plants of it being obtained in three or four years from the time when the seeds are sown. *Corypha australis* is a common kind also largely grown; it is hardy in character, and, being neat in appearance, is largely in demand for room decoration—a situation in which it lasts in a healthy state for a longer period than most other Palms. *Livistona altissima* is likewise largely in demand, but, as seeds of it cannot be obtained in very great quantities, it is seldom found in the market in large numbers. Another good Palm, equally difficult to procure, is *Rhapis flabelliformis*; it has a graceful habit, and, when grown to a height of 2 ft. or 3 ft., is very handsome. Another excellent Palm is *Cocos Weddelliana*, a light and elegant kind which has not been very long in commerce, but, seeds of it having been obtained in large quantities, it will, no doubt, be largely grown for market in years to come, if it will but stand the rough usage to which such plants as are taken there are subjected. *Areca crenata* and *A. Herbsta* are both dwarf, compact growing Palms of great value for market purposes; their stems are furnished with sharp, black spines, their stalks are of a reddish-bronze, and the under sides of the leaves are beautifully glaucous.

CLUB MOSSES.—These are grown by thousands by growers for market. The bulk of the plants, however, are not sent to market, but are disposed of to decorators on a large scale, such as Mr. Wills, of South Kensington. They usually consist of *Selaginella denticulata*, grown in damp places under stages, and similar positions where little else would succeed. One of the best cultivators of *Selaginellas* near London is Mr. Elliott, of Fulham, who makes a speciality of them. He grows his plants in heated pits, close to the glass; they are never shaded except during very hot sunshine, and more bushy or sturdier plants could not be. Old plants are divided into small pieces, and four or five of them are pricked into 5-in. pots at equal distances apart. They are then subjected to a warm, moist temperature until fresh roots are emitted, and, as soon as they begin to cover the surface of the pots, suffi-

cient soil is added to form a mound, into which the plants soon root, and, when they have become well established, they are copiously watered overhead daily through a rosed watering-pot, and are freely exposed to light and air. The best plants are picked out as required for market, and the vacancies are filled up with younger ones. *Selaginellas* grown in this way are greatly preferred by purchasers for decorative purposes to those grown in damp and sunless situations, because they better withstand the heat of rooms, and, under any conditions, last perfect for a much longer period. *Selaginella formosa* is grown largely in 5-in. pots, both in the shape of bushy little plants and pyramids. Plants of it in the latter form have a very handsome appearance, and are much used for room decoration, as, if kept warm and moist, they last good for a considerable time. The soil used for Club Mosses is rich sandy loam, peat, and leaf-mould or rotted cow manure, with broken bricks or pots added to keep the soil porous. As regards culture, abundance of water at the roots and overhead, and a warm temperature, are the chief points to be observed.

DRACENAS.—These are favourite market plants, and always command a ready sale at good prices. In addition to their fine appearance, they withstand the heat of rooms and comparatively rough treatment for a long time without apparent injury; hence their popularity. Growers for market propagate them with remarkable rapidity, *i.e.*, when they have a good stock of old plants on which to operate. The old *D. terminalis* still remains the best of the genus for market work; it is harder than any of the newer kinds, and its foliage is bright and lively. *D. Cooperi* is also a good graceful-leaved kind, and *D. Shepherdii* is considered an excellent plant for all purposes. Several of the green-leaved kinds are likewise grown, but those with coloured foliage are most remunerative. A new sort, with green and white variegated leaves, has lately been introduced by Mr. Wills, of Anerley. Its habit of growth is similar to that of *D. terminalis*, of which it is a variety. This kind, which has been named *D. t. alba*, will, no doubt, be grown to a large extent when the stock of it has become plentiful. Market growers propagate *Dracenas* by cutting up the stems of old plants into pieces, each of which contains an eye. These are placed in Cocoa-nut fibre, on a strong bottom-heat, and, thus situated, they soon commence to push young shoots. Here they are allowed to remain until the shoots have attained a height of 2 in. or 3 in., when they are separated from the parent stock and placed singly in small pots filled with sharp sandy soil and plunged in a brisk bottom-heat. In this way they soon take root, and are afterwards potted on until they are in 5-in. or 6-in. pots, sizes in which they are always taken to market. Some propagate *Dracenas* by taking off the leaves with an eye at their base and a piece of the old wood, while others take the full-grown tops off old plants and strike them at once in pots of the proper size for sending to market. Abundance of water, heat, and air are the chief essentials as regards the successful culture of *Dracenas*, and the large, handsome plants that are grown in such small pots are quite marvellous.

SOLANUMS.—About Christmas time there is a ready sale for these, and, indeed, throughout the whole of the winter there is a large demand for them. Market growers possess several varieties of them, but none are greater favourites than Weatherill's Hybrid, which is dwarf in habit and produces masses of large, bright scarlet berries. Some plant out their young plants in the open ground and

PLATE CLIX.

RHODODENDRON CINNABARINUM.

Drawn by J. N. FITCH, F.L.S.

pot them in autumn, but the most successful way is that of striking them in spring from cuttings which are obtained from old plants introduced into heat early in the year. The cuttings are inserted ten or twelve together in 5-in. or 6-in. pots, and are plunged in bottom-heat, in which they soon form roots; they are then potted singly in 3-in. pots, and, after having become well-established, their shoots are stopped, which induces them to break and form bushy little plants. They are next shifted into 5-in. and 6-in. pots into good holding loam and sand. They are then arranged on wide, airy stages, on which they are allowed plenty of room, in order to induce them to grow short-jointed—a condition in which they yield more berries than they otherwise would. Thus circumstanced, they remain until their fruit is set, a free circulation of air being afforded them whilst they are in blossom. When the berries are fairly formed, manure water is given them, which imparts to the leaves a healthy, deep green appearance, and helps the berries to swell. At this stage the plants are placed out-of-doors in the sunniest position that can be found for them; here the berries soon colour, and, when that occurs, the plants are taken to market. Late batches are finished off in houses in a moderately warm temperature.

ASPIDISTRA LURIDA VARIEGATA.—This is one of the most valuable of market plants; its leaves are beautifully striped with green, yellow, and white, and plants of it will continue to thrive in the same pots for a great length of time, and the heat and dust of rooms affects it but little. It is, however, a plant of comparatively slow growth, and few cultivators can obtain enough of it. It is increased by cutting up the roots in spring, potting them, and plunging them in a brisk bottom-heat until well established, after which the plants grow perfectly well in a greenhouse temperature.

C. W. S.

Large v. Small Plants of *Eucharis amaranica*.—This is such a general favourite, either in the form of cut flowers or otherwise, that whatever course of culture yields the best results is the one that should be followed. I have hitherto thought it best to grow good single bulbs in small pots, and by resting batches of plants in succession, I have had a constant supply of fine blooms; but where large numbers of flowers for cutting is the object in view, I think that large pots filled with bulbs will, as a rule, yield the best results, and if required for decorative purposes, there are few plants that combine the good qualities of a flowering and fine-foliaged plant so well as this *Eucharis*. We have at the present time several large specimens of it coming into flower, each furnished with, on an average, twenty spikes of bloom. They were in full bloom in November last, and were kept quite cool until near Christmas, in order to preserve their flowers, which we used in large quantities for table decoration. Since that time they have been subjected to ordinary stove temperature. Being starved from want of pot room, we have supplied them with an unlimited quantity of tepid liquid manure, which few plants like better than the *Eucharis*. Many of the old flower stalks have not yet decayed, but I find that fresh ones are shooting up vigorously beside them.—J. Groom, Linton Park, Maidstone.

Sowing Sweet Peas.—Sowing these where they are to bloom is much to be preferred to sowing them in pots or boxes; and if I were asked to name a time on which to sow them, I should say the middle of March, if a good long season of bloom be wanted. Last year I sowed at the time just named in the open ground, and also a few in pots, for the sake of experiment, in fact, they bloomed till the flowers were killed by frost. I find that if one wants them to bloom for a long time continuously, it is a good plan to cut off any pods that may form on them as soon as they are visible, as the pods if left on the plants exhaust them, and they soon cease blooming profusely.—J. C. F.

The name *cinnabarinum*, by which this *Rhododendron* is popularly known, has been printed on the plate, but its proper name is *Blandfordiaeflorum*, a species, although closely allied, and perhaps even connected by intermediate forms, very distinct, if we confine ourselves to the typical forms. This, however, is the true *Blandfordiaeflorum*, which is as superior to any of the varieties of *cinnabarinum* known to me as some of the hybrid varieties are to *ponticum*. If the coloration of *R. cinnabarinum* has undergone no deterioration in Hooker's "*Rhododendrons of Sikkim Himalaya*," t. 8, then the name would indeed appear to be more appropriate for the present plant than for typical *R. cinnabarinum*. Nevertheless, our plant could not have a more suitable appellation, for its flowers forcibly recall those of the magnificent Australian Liliaceous genus *Blandfordia*. As *R. Blandfordiaeflorum* has got into cultivation under the name *cinnabarinum*, it may be worth while pointing out how they differ. In the first place the flowers of the latter are scarcely more than half the length of those of the former, and they are of a more open bell shape. In the shape of its flowers *R. Blandfordiaeflorum* reminds one more of the *Malayan Island* species. *R. cinnabarinum* is a variable plant, and Sir Joseph Hooker says that "neither of the figures in his '*Rhododendrons of Sikkim Himalaya*' (that is to say plate 8 the type, and plate 7, under the name of *R. Roylei*, now regarded as a variety of the other) gives a good idea of the plant, which forms a rather elegant bush, about 8 ft. high, conspicuous in May and June, on account of its elegant blossoms, which form very loose and graceful heads of long, pendulous flowers. The figures are from stunted specimens in very exposed situations. The leaves are not usually reticulated, except under these conditions. It is universally considered poisonous to cattle and goats; of the latter I have seen many die from eating either of this or of a species of *Andromeda*. If employed as fuel the smoke causes the eyes to inflame and the cheeks to swell." This rather long quotation is from the "*Botanical Magazine*." It is given in the text accompanying plate 4788, which is a representation of *R. cinnabarinum* var. *pallidum*, a variety grown in the Horticultural Society's garden under the name of *R. theaeiflorum*. A part of this quotation, that relating to the poisonous properties of *R. cinnabarinum*, I remember having seen in the second volume of Hooker's "*Travels in India*," but not that relating to the "long, pendulous flowers," and I cannot help thinking there is some mistake, because all the specimens and figures I have seen of the varieties of *R. cinnabarinum* have open, bell-shaped flowers. Moreover, this opinion is strengthened by the fact that Sir W. Hooker subsequently, and, shortly after its introduction, figured *R. Blandfordiaeflorum*. In the "*Botanical Magazine*," at the place quoted, three varieties of *R. cinnabarinum* are distinguished, namely, the typical variety, the variety *Roylei*, and the variety figured, *pallidum*. It seems probable that Sir Joseph Hooker's notes got mixed in some way through not having the plants before him at the time of writing. Both species inhabit the same region, at an elevation of between 10,000 ft. and 12,000 ft., or nearly up to the snow line; they are, therefore, amongst the hardiest of the Sikkim *Rhododendrons*. Respecting the plant here figured, Mr. Garland, Killerton, Exeter, writes as follows:—"Some fifteen or sixteen years ago, having several Sikkim *Rhododendrons* in pots which did not flower satisfactorily, I determined to plant them in warm, sheltered situations in the pleasure grounds, and accordingly planted them in a high, perfectly-drained south slope, the soil being chiefly decomposed vegetable matter and leaf mould, and the subsoil rock of volcanic origin. They have grown luxuriantly ever since. *R. Blandfordiaeflorum* has flowered for several years past as freely as the common *R. ponticum*. The plant is now 9 ft. high and from 6 ft. to 7 ft. through, the leading stems being erect in habit and the side branches rather pendent. The trusses of flowers from the latter are somewhat like large bunches of *Fuchsia* flowers; they are also sweet scented. The plant withstood the severe winter of 1866 unsheltered with impunity, and it

RHODODENDRON CINNABARINUM

remains uninjured by the severe weather of the present winter, as I have to-day (January 20) examined the wood, leaves, and flower-buds. All lovers of *Rhododendrons* should give this unique and hardy species a prominent position in their collections, however small these may be, as I feel sure they would not be disappointed. It is also very beautiful in the form of cut flowers. It is spoken of by those who have seen it here as one of the prettiest plants in the pleasure-grounds. I hope this season to send you some good trusses of *R. Thomsoni*, as it is well set with flower-buds. Both the above have a sunny situation, and are well sheltered from cold winds—north, east, and west—by other evergreens."

Such is Mr. Garland's account of this fine shrub, but it must be remembered that he writes from that part of the kingdom, where the climate is eminently favourable to the growth of *Sikkim Rhododendrons*. W. B. HEMSLEY.

GARDENING FOR THE WEEK.

Stoves.

Potting.—Such plants as were started earliest should now be potted, for in the case of stove subjects that have attained about the size to which they are to be grown, the usual course is to remove a good portion of the soil to admit of its being replaced by new material, in carrying out which many of the roots must be disturbed, and some sacrificed, and, where too much young growth has been made before this work is done, it naturally receives a severe check, which, for a time, has a stagnating influence that prevents the free development of the shoots essential to the production of an abundance of bloom. With all such plants as the twining section of *Clerodendrons*, that show their flowers almost simultaneously with the commencement of growth from the ripened wood, where the limited root space which they at present have necessitates larger pots, there should be no disturbance of the roots further than the removal of the old socks, as this would almost be certain to have the effect of limiting the amount of bloom produced. The room given to the various species of plants grown that naturally attain a considerable size will, to some extent, need to be regulated by the space at command, but free-growing subjects like *Allamandas*, *Bougainvilleas*, *Clerodendrons*, *Vincas*, *Tabernaemontanas*, *Hibiscus sinensis*, and others of similar habit, where expected to produce the full complement of flowers of which they are capable, need to be grown to a good size, to secure which they must have sufficient root space.

Propagation of Autumn and Winter Flowering Subjects.—Plants of such kinds as *Plumbago rosea*, *Sericographis Ghiesbreghtiana*, *Thyracanthus rutilans*, *Eranthemum*, *poliochellum*, *Euphorbia jacquiniiflora*, and *Aphelandra cristata*, that were recommended some weeks ago to be headed back with a view to producing cuttings, may shortly be expected to have made sufficient growth for the purpose. In the case of all subjects of the above description, I have found that when cuttings are taken off with a heel—although this is not absolutely necessary with more than a few—they will make stouter plants, with less disposition in the cuttings to draw up weakly before roots are formed, than when severed at a joint in the ordinary way; for though it may be argued that there is time enough for the newly struck stock to acquire strength, if a little observation be directed to the subject, it will be seen that plants from the stout, sturdy cuttings, will always keep ahead of those that were weaker at the commencement.

Dichorisandras.—There are several species of these that deserve to be much more generally grown than they are. Their distinct erect habit is held by those who want to make every plant conform to the dwarf, bushy shape to be an objection; but in reality it is an advantage, as in assemblages of plants either large or small, diversity of general character is the greatest charm. Upright plants, such as the *Dichorisandras*, forming as they do stout cane-like shoots from 2 ft. to 3 ft. in height, well furnished with handsome leaves and terminating in conspicuous heads of beautiful flowers, are among the most telling subjects that can be grown for late summer and autumn blooming. For those who are not acquainted with them, I may say that their habit is not unlike that of a miniature *Canna*, the shoots being produced very similarly from a fleshy sort of crown. Where they have been kept tolerably warm throughout the winter, these *Dichorisandras* will now be pushing shoots of sufficient size for cuttings. These should be taken off from the base, inserted in small pots and struck in the usual way. Old plants that bloomed last year and that have several stems may be divided, so as to confine them to one, two, or three, according to the intention of the cultivator. *D. mosaica*, and *D. vittata tricolor*, are both handsome kinds.

Aphelandra aurantiaca Roebli.—The flowering of this plant, like that of most others, is considerably influenced as to time by the treatment which it receives, but, where it has been kept tolerably warm, it will shortly be in bloom, and will form a conspicuous object in the stove or intermediate house amongst plants of dwarf habit, and also for intermixing with *Orchids*. The ease with which it can be made to produce its fine heads of orange-red flowers in small pots when only a few inches high bestis it more than most subjects for growing in quantity. As soon as the earliest-bloomed exaulps are out of flower they should at once be placed under conditions that will induce them to produce cuttings for propagation.

Francisceas.—The beautiful, distinct, violet-purple flowers borne by most of these plants sufficiently recommend them to the attention of cultivators, who, moreover, find them to be easily grown and propagated. *F. calycina major*, *F. eximia*, *F. Lindenii*, and *F. confertiflora*, if well managed, will give a succession of flowers from the commencement of the year up to midsummer. *F. Lindenii* is one of those plants that have been for some time in cultivation, but which many growers have doubtless not seen, or it would be more generally met with. It is a compact-habited kind, as free in the production of bloom as *F. confertiflora*, and one which retains the colour of its flowers better than that species. Cuttings of any of these put in now and grown on freely through the summer will make nice small flowering plants in 6-in. or 7-in. pots next year.

Æchmeas and Billbergias.—These may now be propagated by division of the crowns, which, if slipped off with a piece of stem attached to each, and placed in 5-in. or 6-in. pots, well drained, and filled with a mixture of either peat and sand or loam and sand, with a liberal sprinkling of pot shreds or charcoal, will soon root and form young growth from the dormant eyes at the base of the lower leaves. Nothing is more useful than these *Æchmeas*, which retain the colour of the bloom stems and seed vessels for so long a period unimpaired after the flowers are absolutely over, as to be scarcely distinguishable from plants really in bloom. They are also useful either for standing about amongst fine-leaved plants on the stages of the orchid house or conservatory, and through the autumn in halls, corridors, or wherever small-flowering subjects are required. The large-growing *A. Mariæ Reginæ* is a very distinct and handsome variety, a striking object when either in or out of flower. The *Billbergias* have a like habit of growth, but they are much taller and do not last nearly so long in bloom. Some of the largest growers with their reflexed, drooping, long, strap-like leaves are very beautiful when not in flower.

Bertolonias and Fittonias.—It is not unusual to see these elegant small-growing plants lost sight of amongst things of larger stature; yet, independent of their individual beauty, they add much by contrast to the larger growers when associated with them. *Bertolonias* require a good deal of warmth to bring out their true colours, but, when well managed, the markings of such kinds as *B. Van Houtteana*, *B. margaritacea splendens*, and *B. superbissima*, are scarcely surpassed by those of the best varieties of *Anæstochilus*. They will strike root freely now in the shape of cuttings made of the half-ripened shoots kept moderately close, moist, and warm. The *Fittonias* root as readily as weeds, and, in addition to their adaptability for cultivating in suspended baskets, small pots, or pans, they may with the best advantage be used as edgings for stages in stoves or intermediate houses, or for covering out-of-the-way corners, where few plants can be found to thrive freely under so little light. In the case of all such plants as the above, care should be taken to see that the stock from which the cuttings are obtained is free from insects, especially scale and bug.

Orchids.

few indoor cultivated flowering plants admit of the time of blooming being varied so much as *Orchids*. Such portions of the spring and early flowering stock as are required to be kept a little later than usual should at once be put in somewhat cooler quarters; this applies to such as *Cattleyas*, *Lælias*, *Dendrobis*, *Epidendrums*, *Brassias*, *Angulos*, *Chysis*, *Oncidiums*, and *Trichopiliis*, that bloom from the mature growths after resting, as any attempt to retard the flowering of plants which bloom from the current growth now in course of formation would be certain to result in imperfect development and injury to the plants. With what retarding is attempted care must be taken not to keep the plants cooler than each respective species can bear, and in consequence of their being in a lower temperature there should be comparatively less moisture given both to the roots and in the atmosphere. At the same time no cold air should be allowed to come in contact with them, for I found when I was growing *Orchids* for exhibition that many species could be retarded a considerable time in a somewhat lower temperature than is usually considered necessary, providing the other conditions which I have mentioned were complied with, but that they would not bear cold external air being admitted to them. Whilst such plants as the above are

at rest, it gives an opportunity for going several times over them, with a view to eradicate any scale with which they may be affected.

Scuticarias.—The long, drooping, thong-like leaves of these plants render them worth a place in any collection of Orchids, even if they never produced a flower, so distinct are they from everything else. S. Steeli and S. Hadweni are both well worth growing; they are often considered difficult to bloom, but I never found them so, if the blocks to which they were attached were kept hung up during the growing season near the roof, wherethey got plenty of light, and the plants were afterwards submitted to a long rest. They may now be expected to be about pushing up their large, singular-looking flowers, and care must be taken that much water be not allowed to lodge about them. It is necessary to allude to this for those who may not have previously grown them, as I have frequently seen the young flower buds destroyed by syringing before it was noticed that they were in existence. This may be avoided by moistening the roots, which will usually be met with extending below the block. Plants of these not yet strong enough to flower, and that require re-blocking, ought to be attended to at once before any growth commences; nothing but the hardest and most enduring wood should be used, for their roots adhere remarkably fast to whatever they may cling, and live much longer than those of many others.

Bulbous Calanthes.—There are few plants that exhibit so much difference between being well grown and indifferently as these. A monard Orchide, there are not many that need so much light as they do, although the foliage is too thin to bear the direct rays of the sun. There is no situation in which they succeed so well as hung up near the roof over the paths, and where they can be so accommodated, they should be grown in pans. They will very shortly require potting, which will be seen by the growth buds beginning to swell at the base of the pseudo-bulbs; their roots are altogether of an annual character, and those produced last year will be all decayed; but instead of cutting them wholly away, it is better to shorten them to about 1 in. in length, the portion retained, being made firm in the new material, will hold them in position until fresh fibres emitted from the bottom of the young growth get hold of the soil.

Shading.—The sun is often very powerful at this season, if only for a short time. It is not at all advisable to shade the plants sooner than is absolutely necessary, but the position of the house in which they are grown will determine how soon it is requisite to put on the blinds, which by all means should be movable. Houses that stand with the ends east and west expose the occupants in the middle of the day very much more to the sun than when in the contrary direction, and with such it will frequently be found needful to get on the blinds at once.

Roses.

Where a sufficient stock for growing on in pots with a view to forcing next winter, has not already been potted, this must no longer be delayed. Young plants in small pots that want more room should at once be shifted, placing the whole in cold pits or frames, and keeping them a little closer for two or three weeks, until the roots have begun to act; but in the case of plants that are thus undergoing a preparatory process, there must be no attempt at hurrying them on into growth, as the stouter they are the better they will fulfil the object for which they are intended. A slight syringing overhead in the afternoons, when the weather is bright, will help to keep down insects; to still further effect the destruction of green fly, dip any plant that is found infested in Tobacco water. A vigilant eye must be kept on the general Rose house, to detect aphides and red spider, fumigating, if there becomes a necessity for this, very cautiously, otherwise the foliage will be injured. Ventilation should yet be confined to the roof, as the external air is still much too cold for admission at the sides.—T. BAINES.

Flower Garden.

Auriculas.—Airing and watering must now be carefully attended to. The offsets that were taken off require some care; many of them being small and having but slight hold of the soil, are apt to be washed out of the pots when applying water. We use very small pots, smaller than 2½ in.; they are such as are used by raisers of seedling Orchids. Offsets that were placed in these pots last autumn have wintered very well, and we are now potting them off singly into small pots. Last October, or early in November, we planted out a large collection of the choicest Alpines, and not one plant has been injured by the severe weather, showing that they are neither affected by wet nor cold; they are now growing away very freely, although we had 9° of frost the other night, after nearly 6 in. of snow had melted over them during the previous day.

Carnations and Picotees.—The few fine days which we have had have started these into active growth, even though it is cold at night; thus showing as how eager vegetation is to escape from the trammels of winter. We would not start to pot them as yet, but the plants have not been well treated during the winter, owing to want of time to pick off dead leaves, and to stir the surface soil in the pots. We must either do this now or pot them, and it will save time as well as forward the work by doing the latter. It may be as well to say that 8 in. pots are large enough for a pair of plants. The soil should be good loam, well enriched with rotten manure and a fourth part of leaf-mould, with the addition of a little sand; press the soil in with the fingers. Many turn the plants out of doors as soon as they are potted, but it is better to keep them under glass for a few weeks, if possible.

Dahlias and Hollyhocks.—It may be as well to remind cultivators that as these are now entirely under their control under glass, a few days' inattention to their requirements may ruin the prospects of a good display of flowers. I have seen them placed in close Vineries, overhated by the leaves until the growths had spindled up very weakly. Wherever they are, therefore, they must be placed close to the glass, and after they are well rooted, admit as much air as possible. If they are well established and healthy, shade is injurious. Inure them to stand in cold frames with the lights removed as soon as weather permits.

Pansies and Pinks in Beds.—The named varieties of the former certainly do not stand well during a severe winter, unless they are well established; our beds look very miserable. By far the easiest way to make a good display of show Pansies is to sow seeds of them in August or September; perhaps August is the best month. In that case the plants may be set out in beds before the weather is severe; or they may be wintered in boxes and planted out early in spring, under which treatment they make a grand display. Pinks are looking fairly well, and when a few blank spaces are made good, they will be all right.

Phloxes, Delphiniums, Pyrethrums, &c.—If these, or any plants of a similar character, in beds or borders have to be increased by division, no time should now be lost in doing so. They are all beginning to start, and their growth will experience less injury now than if the work of division were left until later. Although many have no other way of propagating their Phloxes than by chopping up the clumps with a spade, it is a shiftless plan, and never gives good results, such as may be obtained by taking cuttings, as has been previously recommended.

Polyanthuses.—As I write, the first flowers of these are opening, and how very beautiful they are when they first expand! the clear golden edge and centre and the black body colour are most striking. The Polyanthus does not seem to go so entirely to rest as the Auricula, inasmuch as we generally have a few flowers open before March comes. They require plenty of water at the roots now, but care must be taken not to wet the leaves so much as to cause them to damp off. Mats must be placed near the glass to prevent injury from frost.—J. DOUGLAS.

Spring Bedding Plants.—These have been greatly injured and retarded by the protracted winter, and any reserve stock there may be should now be utilised in making good all blanks, or as supplementary plants to any that do not seem likely to start kindly into growth. Well press the whole of the plants into the ground; such as have not large roots the frost is sure to have upheaved, and, if not made firm, the first dry day will cause incalculable injury. Beds of Pinks and Carnations also require similar attention, after which a rich top-dressing of loam and manure should be applied over the entire surface of the beds. If the weather should prove severe it will be desirable to protect beds of Hyacinths and Tulips that are far advanced in growth; a few evergreen branches laid over them will prove an efficient protection. Now that the bulbs that usually fringe shrubby borders can be seen, all such borders should be lightly "pointed" over, i.e., if the shrubs have previously been trimmed, not in too formal a manner, but simply so as to induce an equable balance of branches or shoots. Coniferous trees may also now be trimmed; a denser growth is ensured if occasionally vigorous-growing trees have the tips of the longest branches cut off. Picea Pinnapo, P. cephalonica, P. nobilis, and Cryptomeria japonica are specially liable to grow straggly if not thus pruned occasionally. The symmetry of the smaller-growing shrubs is also much improved by occasionally taking off the point of a shoot that is outdistancing the other, or a crooked or duplicate leader. Hedges and other fences that are kept clipped may now all be operated on. Turf levelling and verges trimming should now be proceeded with; also laying and relaying Box and other edgings. The long and severe frost has found out the weak places in walks; therefore, these should now be well drained and re-

gravelled; indeed, the whole of the walks should be thoroughly consolidated by frequent rolling before the drying winds of March set in. We now, surely, may anticipate freedom from very keen frost, therefore the hardy Fernery and rock garden may be thoroughly cleaned up, the dead fronds of any Ferns that were left for winter protection may be cleared off, and the ground dug or pricked over, adding fresh peat soil where requisite, and filling up any gaps that may have been caused through the severity of the winter. Rock plants, in common with others, have suffered to a certain extent; *Andrietta Campbelli* and *Phlox vernae*, which, as a rule, are amongst the hardiest, are, according to present appearances, the most injured; all require pressing firmly into the soil, and, where necessary, fresh soil added. Many kinds will now bear division, and if done now the parts severed will have time to get root hold before drought sets in. Cannas that were lifted in the autumn and stored in sheds may now be divided, potted, and started in gentle warmth. It is to be feared that those wintered in the open ground, if not killed, must be seriously injured; so that it is necessary to make the most of the reserve stock. Dahlias should be placed thickly together in boxes filled with vegetable mould and put in a warm house, say in a warm temperature of from 65° to 70°, when they will soon produce shoots, which, if taken off when about 3 in. long and inserted singly in 3-in. pots in a compost of leaf soil and loam, and plunged in a bottom heat of 75°, will strike root in a week or two, and make the finest of plants for putting out at the end of May. *Alternantheras*, *Coleuses*, and *Iresines* should all now be encouraged to produce cuttings by giving them good positions and abundance of heat; the former strike freely in any warm place. The system which I like best is to make up a hotbed, not more than 2 ft. in thickness, and, having placed the frames on it, the compost is put in; it consists of half loam and half leaf mould, the whole being made firm, and as soon as the heat is up the cuttings are inserted and root in from five to ten days; here they remain until they are transferred to the flower garden at the beginning of June. Those put in at this early period have to supply the bulk of cuttings for the thousands of plants that are required, but there is no difficulty about this, for under such conditions they grow like weeds.—W. W.

Indoor Fruit Department.

Vines.—There having been no sunshine to put the sap in motion, or sufficiently hard frost since the fruit was out to necessitate the firing of late Vineries, the Vines are this season having a more effectual rest than has been possible for several seasons past, and they may be expected to be proportionately benefited. Since harvesting the fruit by the end of the old or beginning of the new year has been adopted, there has been a general improvement in what were once called the coarser varieties of Grapes, the reason being that such Grapes had not, under the old *végété*, a sufficiently long season in which to ripen, and, as a rule, even now the Vines are not started early enough for them to get fully ripe as they should be by the beginning of October. All late Vineries should be closed by the end of this month; therefore, let the necessary cleansing and top-dressing of borders be done forthwith, and, presuming that the borders are inside, they should have repeated soakings of tepid water, in order to thoroughly moisten every particle of the soil. If the drains be clear, there need be no danger of an over supply; at all events, it is better to err on the side of giving too much than too little. The same remark is applicable to early houses that have inside borders, only it is advisable that the water applied to these be of the same temperature as that of the house; even a few degrees warmer is preferable. There is still a lack of sunshine, consequently, there is very little progress in growth, and, though the season is advancing, be content to proceed slowly rather than risk the permanent injury which the Vines will receive by continuous hard firing. As soon as it can be seen which bunches are best formed, cut off all others not intended for a crop; one day's waste of the energies of the Vines, were such bunches allowed to remain, would be injurious to those left to ripen; and the same may be said in reference to thinning out the berries; all such thinning should be finished by the time when they attain the size of Peas. Such constant firing as has this season been required, will lay the foundation for attacks of red spider; therefore, as a preventive, keep the atmosphere charged with ammonia, either by occasionally sprinkling the walls and floors with manure water—particularly when closing up—or by keeping a supply of fresh stable litter strewn on the floor of the house. The ammonia-charged atmosphere thus engendered is inimical to insect life, and in the highest degree beneficial to the Vines. Some care and judgment is, of course, needed in the application, both as when to apply it, and in what proportion. With regard to the former, the only time that it is likely to be injurious is when the Vines are flowering (as it must be obvious that a drier atmosphere is then required) and also when the Grapes begin to change colour, when its application should be entirely

withdrawn. Then as to proportion. No one would apply so strong a dose as to make the eyes water on entering the Vinery, and yet I once heard of this being done, the result being that the foliage got injured. Pot Vines will require incessant attention as to moisture; usually they are placed in close conjunction with hot water pipes when, if not plunged, they soon get dry. Where such provision can be made for them after the fruit is set, they would do best placed on a bed of rotten manure, and the roots which protrude from the bottom of the pot might be allowed to ramify in it. Vines that have been cut back for the purpose of making fruiting growth for next year should be scrupulously prevented from rooting beyond the limits of their pots. As soon as Vine eyes have formed roots, take them out of bottom heat and grow them on without it. The succulent, fleshy rootlets that are made in bottom heat soon perish if a check of any kind occurs, and though the growth of the Vine may not be so rapid without bottom heat, it will be far more lasting and fruitful.

Pines.—After such a long spell of sunless weather it will be advisable to have some slight shading material in readiness to be applied for an hour or two when the sun is brightest till the plants get inured to the change, when it must be entirely dispensed with, except in the case of newly-potted plants, which may require shade till the roots get to work in the new soil. With more daylight an increase of air moisture is necessary, more especially to plants that have done flowering, and that are swelling their fruit. In the case of any plants that have missed fruiting, if convenient, let them be placed by themselves, and be kept comparatively dry, both at root and top. Such treatment will soon have the desired effect, when they may be returned to their former quarters. Succession plants that have been wintered in 6-in. or 8-in. pots, should not be allowed to get root-bound, but should be at once transferred to their fruiting pots. When doing this be particular that each ball is thoroughly moistened previously, for if put into the larger pot in a dry state it will remain so. If a few of the largest suckers, taken from Queens, now swelling their fruit, be potted and grown on freely, they will make the finest fruiters twelve months hence. Bottom-heat for fruiting Pines should now range from 85° to 90°, in other stages 10° lower will be ample. The atmospheric temperature should be allowed to fluctuate somewhat with the weather. With sun heat 85° or 90° are none too much for fruiters and those that are growing freely, but on cold windy days 15° or 20° lower will be sufficient.

Figs.—These when in full growth are impatient of the slightest approach to dryness, either in the borders or in the atmosphere; a check thus given frequently causes the fruit to drop prematurely, therefore guard against this by keeping them well supplied with tepid water, and ply the syringe freely whenever the state of the outside air admits of it. Give to plants in pots liberal doses of tepid manure water about twice each week, and keep the growths restricted and fruitful, by continued pinching out of the points at every fourth or fifth joint. All houses should now be started, or at least as soon as the weather will admit of the borders having had the needed top-dressing, which should consist of rich loam, well decayed cow manure and lime scraps, made very firm, in order that a certain amount of resistance may be given, to induce the roots to throw out lateral rootlets.

Peaches.—Red spider will be almost certain to get a lodgement on the earliest forced Peaches, owing to the fire-heat that has had to be applied to keep anything at all like a forcing temperature. As soon, therefore, as the fruit is set, syringe the trees freely with clean water of the same temperature as that of the house, and the walls and floors with manure water. Our early houses when in blossom were badly attacked by ants, which, in search of honey, ate out the pistils of many of the flowers. After trying several remedies, the most effectual was that of surrounding the stems of each tree at the base with soft guano, and now there is not a single ant to be seen in the house; those that were previously in the blossoms were waylaid and killed. Forcing should still be proceeded with slowly; lost time can be made up when better weather sets in. Trees in flower, in the absence of sunshine, will need to have the pollen artificially dispersed, either by means of a camel's hair brush, or by well shaking the trellis when the atmosphere is dry. The temperature should be kept in as equable condition as possible; say about 55°.

Strawberries.—As soon as the fruits are set and it can be seen which are likely to swell off most kindly, remove all superfluous berries, about eight to a plant at this early season, will be sufficient. *Vicomtesse*, *Héricart de Thury* and *President* are the only three kinds yet forced, and for several years they have never failed, whilst other varieties have done so, hence our determination to abide by those two sorts. Plants now being introduced into heat, if intended to ripen in the position in which they are first placed, should be set on turves which have received a sprinkling of wood ashes, soot, or bone dust. Into this, by the time the fruit has set and requires extra assistance

the roots will have found their way, and less feeding and watering will therefore be required. Any that have to be shifted from place to place may be similarly treated by using a second pot, placing a good crock over the bottom, and on this one of the above-named manures, mixed with loam in sufficient quantity to form a foundation for the plants to stand on. This is a better plan than saucers, which have no drainage, and consequently the soil often gets sour and stagnant. With the continued absence of sunlight artificial fertilisation is still indispensable.

Melons.—These are sun-loving plants, and if grown with a superabundance of moisture and fire heat, the flabby growth made will not withstand the sun heat, so essential to their well-being. It is, therefore, imperative that they should have as little air moisture and water at the root as is possible to keep them slowly growing till brighter weather arrives. Give air whenever the outside atmosphere is favourable as soon as the thermometer registers 70°, and close as soon as it begins to recede from that figure, giving the plants a gentle dewing overhead when closing up. Sow for succession in bottom-heat, and, as soon as germination takes place, give them a warm position as close to the glass as possible, in order that they may develop a sturdy foundation on which to build a successful growth.—W. W.

Parks and Open Spaces.

Lawns.—During March, if the weather be favourable, Grass seed should be sown where it is desired to form new turf or renew old. This is especially the case on large open spaces, in order that the young Grass may have a reasonable chance of becoming established before they are much frequented, as it is neither practicable nor desirable to enclose portions for this purpose. The first condition necessary to ensure success is that the ground should be efficiently drained, and the whole surface broken up to a sufficient depth to allow of its being levelled, great care being taken that should any portions require a considerable amount of filling up, that the soil be well rammed in thin layers. This would occur in filling up trenches where drain pipes have been laid. Where the surface is composed of gravel or poor soil, it is desirable to give a dressing of good soil, at the rate of twenty cart loads per acre, or more where it is easily obtainable. Having spread this evenly over the whole area, it should be harrowed and rolled until thoroughly pulverised, and any large stones or other rubbish should be gathered off before the seed is sown. Although in favourable situations three bushels of seed is considered ample to sow per acre, I am of opinion that not less than four bushels should be the quantity sown in public parks and open spaces on all those portions to which the public have access. Care should also be taken that the seed is of good quality. From 1 lb. to 5 lb. in weight of white Dutch Clover, mixed with the quantity of Grass seed recommended to be sown per acre, will be found an improvement on dry soils. After the ground has been prepared in the manner described above, the seed should be sown evenly over the surface. To do this a calm day must be chosen; this done, the best way without exception, with which I am acquainted, to bury the seed is to use steel forks, drawing them backwards and forwards until the seed is properly covered. This any ordinary workman will do; neither harrowing nor raking will bear comparison with forks for this purpose. A light bush harrow may then be drawn over the surface, and all stones, sticks, or other rubbish which may have been turned up, picked off, and, lastly, the whole area thoroughly rolled; in fact, the surface cannot be too much consolidated, unless it be of a clayey nature. Lawns treated in the above manner are sure to succeed, and, with favourable weather, may be fairly green in about a month.—CHARLES DENNIS, *Southwark Park*.

Extracts from my Diary, March 3 to 8.

Pruning and nailing Pears. Digging vacant ground. Thinning Grapes. Fainting Vines in late houses. Propagating bedding plants. Pruning Apples. Pruning and nailing Marchal Niel Rose and Clematis. Preparing Pine stove for planting Cucumbers, by making a ridge of manure 8 in. thick and 2½ ft. wide. Earthing up Potatoes in frames. Thinning Grapes in pot Vinery. Propagating Verbenas. Emptying Cucumber house of winter plants and getting fresh plants in. Filling bed in Cucumber house with manure for Melons. Getting in soil for planting Cucumbers in Pine stove. Looking over Apples in fruit room. Sorting Potatoes for growing for exhibition. Sowing Begonia and Amaranthus seed, and potting Palms. Earthing up Peas in boxes in cold houses. Laying turf in hotbed for Melons 4½ in. thick. Preparing Strawberries for forcing. Starting Figs in pots. Rearranging plant houses. Sowing first batch of White Spanish Onions, also of Tom Thumb and summer Cos Lettuce between the Onions. Propagating bedding plants. Preparing house for Melons. Sowing cold frame with Ivory, Marjoram, and Sweet Basil. Sowing Peas in pots for starting in cold houses; also sowing first batch of Brussels Sprouts and Cauliflowers out-of-doors.—R. GILBERT, *Burghley*.

OBITUARY.

DEATH OF MR. NIVEN, OF DRUMCONDRA.

ON Tuesday, February 18, death removed from amongst us one whose name has been intimately connected with horticulture in Ireland for the past half century. The groundwork of the late Ninian Niven's fame was first laid in the gardens connected with the chief secretary's official residence in the Phoenix Park. These he remodelled. Introducing a new and methodic system in all departments, he soon made them worthy of the brief but expressive criticism of the late Mr. Loudon, who, when making a professional tour in Ireland, said "they were the best managed gardens in that country." Mr. Niven's residence here extended over some nine or ten years, during which period he carried off a vast number of prizes at the horticultural shows. About this time the Curatorship of the Royal Dublin Society's Gardens became vacant, and he was then asked to compete for this, the premier post of his profession in Ireland, and was successful in the competition. For five years he discharged the duties that here devolved upon him so entirely to the satisfaction of the Council, that when in 1839, he resigned his post, he received, at the hands of the Royal Dublin Society, a very handsome presentation. During the above period the grounds had been thoroughly remodelled, and great and important improvements made—improvements which have been since further modernised, and, which under the skilful management of his successor, the present curator, Dr. Moore, render the Glasnevin Gardens a credit alike to the profession and to the country.

During the latter part of Mr. Niven's curatorship his time was occupied to a considerable extent in carrying on professional work, and, after resigning his post, he devoted his energies entirely to the career of a landscape gardener, and has since been employed in that capacity in all parts of the country; and it would be easy to point out numerous instances where his art has assisted Nature in a manner only possible to one who was a born landscape gardener. During the thirty-four years of his life devoted to this delightful employment, he further organised horticultural and experimental nursery grounds at Drumcondra, not far from Dublin, where, besides an admirably managed nursery, containing the finest collection of fruit trees in Ireland, are to be found a choice assortment of botanical specimens, and Alpine and herbaceous borders containing mementos of the olden time, when the countess scarlet and zonal Pelargoniums, Verbenas, Lobelias, and other florid elements of the modern system of flower gardening had not seen the light.

Amid the many claims on his time in connection with his professional career, as well as the entire management of his home nurseries and experimental garden, he was a not unfrequent contributor on botanical subjects to the periodical literature of the day, more especially in early life, and we find his name constantly occurring in "London's Magazine." A valuable essay on the cultivation of the Potato, written many years ago, carried off the gold medal offered by the Royal Dublin Society; this was succeeded by a second pamphlet on the Potato disease, and, just before the close of Mr. Niven's residence at Glasnevin, he published a popular guide to those gardens, the first, we believe, that had been attempted of any botanical garden. With the "Guide" proper was incorporated a text book on practical botany, the object being to popularise a science that, at the period we speak of, had but few votaries among the general public. To these may be added one of the best practical treatises on the cultivation of Asparagus, the value of which is fully appreciated even at the present day.

Mr. Niven had attained a ripe old age—eighty years. During his long and useful life he had an almost perfect immunity from illness, rarely having been confined to the house previous to the attack which ended in his death; and the very day previous to this attack, he had been out marking trees in his garden. Up to a few months since he was, for his years, the halest and healthiest of men, looking as though years of work and wonted energy were still in the future. The symptoms of an insidious disease in the course of last year unexpectedly manifested themselves. Born in Scotland, nearly all the years of his manhood were spent in Ireland. We need hardly add that Mr. Niven was the father of the present curator of the Hull Botanic Garden, so well known to many of our readers.

The Weather in Somersetshire.—We have had another return of severe weather, the thermometer being down to 26°, 24°, and 25° Fahr. on Friday, Saturday, and Sunday nights respectively, and we also have about 2 in. of snow on the ground. The latter circumstance is fortunate, as it will protect the young growths which so many of the herbaceous plants had made during the sunny days last week.—J. A. OXLEY, *Innos Hill Cottage, Frome*.

The Weather in North Notts.—The weather still continues here of the most wintry character; it has been snowing all day (Feb. 24), and it now lies to the depth of 4 in. Yesterday-morning

(the 23rd) the thermometer registered 8° of frost, and it seems likely to last, for the barometer is rising rapidly. This second setting in of severe cold will do great injury to vegetation, especially vegetables. All the Broccolies here withstood the severe frost in January very well, having been laid down close to the ground in the autumn, and some of the early sorts slightly protected with litter. Brussels Sprouts and Cabbages for sprouts are, however, all injured and rotting, having been with their long stalks exposed to the cold east winds in December and January. Young Cabbages, Winter Spinach, and Onions are safe as yet, being close to the ground under a covering of snow. Unless we have a very dry and fine March the spring will be a backward one and vegetables very scarce and dear. I am afraid that the fruit tree blossoms will likewise open weakly and the fruit set badly after such a protracted and severe winter and early spring.—W. TILLERY, *Wellbeck*.

GARDENER'S FRIENDS.

THE GOLDEN-EYED FLY OR LACE-WINGED FLY.

(CHRYSOPE PERLA.)

THIS insect which is generally tolerably common in gardens and orchards, is one of the gardener's best friends, for its grubs are most deadly enemies to the green fly, a fact which cannot be too generally known, as they should be encouraged in every possible manner. The grubs are not at all particular what kind of aphids they attack, for they have been found among

Chrysopa perla.

many different species, from the common green fly of the Rose to the nearly black species found on Poppies and other plants. It is difficult to recommend any particular course of action by which these useful insects may be protected, but every gardener should make himself familiar with them in their various stages of development, so as to avoid injuring them when they are met with. If any of the grubs are found whilst cleaning a plant infested with green fly, they should be carefully removed and placed on some plant where they can be of use. The genus to which this insect belongs, and a nearly allied genus (*Hemerobius*) contain a considerable number of species whose habits and economy are very similar to those of the one I am now describing. The Natural Order to which they belong is called Neuroptera or "nerve-winged," from the great number of nervures or veins in the wings, which form a delicate network. The lace-winged fly is a very beautiful insect, with four large, transparent, lace-like, green wings, which in certain lights give lovely rosy or golden reflections, and brilliant golden yellow or green eyes. When touched it emits a most disgusting odour, which is probably some protection from its enemies, for otherwise, it is a most helpless insect, flying very slowly, and having no visible means of defence. The perfect insects make their appearance in the spring, and may be found throughout the summer, during which season there are several generations. They are very short lived, only living a few days. They arrange their eggs in very curious clusters on the leaves and stalks of plants infested with aphides; every group contains

about a dozen eggs which are each placed on the top of a long transparent, hair-like stalk, sometimes 1 in. long. They have often been supposed to be of vegetable origin, as they much resemble the seed vessels of a Moss or some Fungus. It is not known that the females have ever been found in the act of laying their eggs, but it is probable that they touch the leaves with a viscous fluid, of which they have a supply near the extremity of their bodies, which they then raise, drawing out a thread to which the egg is attached. The eggs are thus elevated, probably for security, and particularly from their future prey, which at times are in such numbers on the leaves, &c., that the eggs might otherwise be destroyed. The grubs are hatched in a few days, and immediately commence a war of extirpation against the helpless green flies; they are furnished with a pair of long, powerful jaws, with which they seize their prey, the contents of whose bodies they instantly suck out. They are very voracious, and will empty the largest aphid in less than half a minute. Mr. Curtis placed two in a box, which fought desperately; the conqueror feasted on the vanquished, and soon afterwards sucked the contents from a caterpillar $\frac{3}{4}$ in. long. They

Grub of an allied species.

generally cover themselves with the skins of their victims, or with pieces of Lichen, &c., so that they are very difficult to find. The grubs of some species so clothe themselves with the skins that they are almost as round as balls. They are fully grown in about a fortnight, and then, selecting some fold in a leaf, spin a little round cocoon, about the size of a small Pea, of whitish silk, in which they become chrysalides. The thread is not produced from the mouth, as it is with caterpillars, but from the end of the body. Except in the case of the chrysalides of the last brood, which remain unchanged until the next spring, the perfect insects appear in about three weeks; they are about $\frac{1}{2}$ in. long, and measure from $1\frac{1}{4}$ in. to $1\frac{1}{2}$ in. across the wings. The males are somewhat smaller than the females. It seems almost impossible that such comparatively large insects should come from cocoons no larger than small Peas, but such is undoubtedly the case. Their heads are furnished with two delicate antennæ about $\frac{1}{2}$ in. long, composed of a great number of very fine joints. The eyes are very prominent, and, as before stated, are of a brilliant golden hue; the legs are short and the body soft and slender; the wings are long and oval, very large in proportion to the rest of the insect. When at rest they cover the body like the roof of a house, but they are not folded over one another. The general colour of the insect is pale green or yellowish-green, but there are very beautiful coloured reflections from the wings in some lights. The grubs, when fully grown, are about $\frac{3}{4}$ in. long. Their bodies have eleven very well-defined joints, with a tubercle on either side, from which springs a bunch of hairs, except the last two joints, which do not bear tubercles. They have only three pairs of legs, one being on each side of the first three joints; the last joint, however, is generally used as a foot. Their colour is usually whitish or pale brown with orange or brown spots. The cocoons have already been described. S. G. S.

THE FRUIT GARDEN.

VINES IN RELATION TO ROOT TEMPERATURE.

I HAVE, during the past winter, and up to the present time, made some observations on the progress of Vines in several of the Vineries here, in relation to the temperature of borders. Early in September last I had thirty-six pot Vines from two nurserymen—eighteen from each. They were strong and well-ripened, and were shortly afterwards pruned and rested till the middle of November, when half the number were started at ordinary temperature, and the remainder followed in the same house the first week in December. The pots were not plunged in a hotbed, but simply set on the floor, as closely together as they would stand, and a bandful of leaves was stuffed in between them to keep them moist; all along the roots have just had the same heat as the tops. Owing to the constantly dull weather which we have experienced they are not so forward as usual,

but those started about November 15 are coming into flower at this date (Feb. 21), and those started in December are close at their heels, but they will not be in flower for a week or so; yet another house of second early Vines that have ripened their wood in June last, and that were pruned early in the autumn and started December 1, or at the same time as the second lot of pot Vines, have now shoots about 6 in. long at the hottest end of the house, while at the coolest end the shoots are hardly 1 in. long. Inside the Vines have been treated exactly the same as the pot Vines, but differently at the roots, which are all outside, except a fractional portion inside the front wall that we do not take into account, either in watering or manuring, the roots outside extending 14 ft. from the Vinery, and lying near the surface of the border. When the Vines were started the border had upon it 4 in. of dry litter, and the temperature of the border, 18 in. and 1 ft. from the surface, ranged from 40° to 45°, the weather having been cold, and snow and frost prevailing. More leaves were added to the border and mixed with litter, and later the materials were again turned, but, owing to the small quantity of them, they did not ferment actively and no more were at hand, the demand being greater than our supply for various purposes, no leaves having been procurable since November till ten days ago, owing to snow lying deeply. The result was that the temperature of the border rose but slowly, and when tested, on Jan. 18, the thermometer stood only at 49°, which is about 10° lower than it was last year at the same period, and the Vines are, I should say, quite three weeks behindhand. They are, however, strong and in excellent health, and have not been started earlier than they have been for years back. Of course, the long continuance of dull weather has had a retarding effect upon the Vines, but so has it also had upon the pot Vines, yet the latter are at least a full month in advance, and are looking strong and well.

Now, what can be the cause of the difference in the progress of the two houses? I can attribute the backwardness of the second Vinery to nothing but the colder root temperature. The Vines in both cases consist of the same variety; they have been treated alike, are about equal in vigour, and the second early Vinery had the advantage of being earlier ripened and pruned, and therefore readier for a start. Take another instance. A mixed Vinery, which has in previous years been started in March, was this season started at the beginning of February; the roots are all inside and cannot get out, and the border was standing at 50° at the time of starting, and it is now (Feb. 21) 55°, and sometimes a little under it. The result is that the Vines have responded at once, and the bunches of such kinds as Duke of Buccleuch, Golden Champion, and Hamburgs are just showing themselves, and if they progress as fast as they promise to do the crop will be ripe about as soon as that in the second early Vinery before mentioned.

A good deal has been said about the inutilty of fermenting materials. They have been said to be almost non-effective in communicating heat downwards to the soil, and as rather preventing the escape of heat than communicating any of themselves. This matter I have also investigated during the past winter. Early in January a Muscat Vinery border outside was covered with 1 ft. of leaves and litter in equal quantities, and about the end of the same month the bed was increased to a clear depth of 18 in. by adding more leaves and litter, which were carefully turned and mixed, and since then it has not been touched. When first covered, the border stood at 45°. After being covered, the temperature began gradually to rise, and after the second addition and turning the heat of the fermenting materials rose to 75°, and that of the soil, 18 in. below the surface, to 60°; the temperature was also still going up, and this week a thermometer inserted in the border, 8 ft. from the Vinery front, registers 68° 2 ft. below the surface, which is higher than I want it, the temperature of the litter close to the soil being 70° exactly, and now declining. These observations have been verified over and over again, and by others besides myself, and the temperatures were registered by a proper bottom-heat thermometer, 2½ ft. long, in a copper case.

Though perfectly well aware of the effects of fermenting materials in heating the soil, I did not think that so gentle a heat would communicate such a high temperature to it, to the depth of 2 ft., but the fact is as I have stated, and shows how groundless are the suppositions of those who have, on the one

hand, asserted that the litter burns the roots, and, on the other, that it does not heat the soil to any sensible extent.

J. S. W.

— In January last I visited a friend whose early Vines were in a bad state. They had been started in the end of November, and had broken very irregularly, some of the shoots being much longer than others; the leaves too were small and weak, and the shoots the same, showing but small, deformed bunches; in fact, they looked wretched. I asked what had gone wrong with them, as the wood of last season seemed to have been well ripened. I was told that the heat had been kept at from 50° to 55° at night, with a corresponding rise by day; but as the Vines were planted outside I began to examine the border, which had not been covered. I found it to be a raised one, the greater portion of it being above the ground level, the situation being damp. It was well drained and the soil good. The usual method, until this season, had been to put on it a good coat of dry leaves previous to starting the Vines early in November, and then to thatch it with dry straw. But this year no such protection had been given, and when the border was inspected we found it to be frozen some 6 in. or 8 in. deep; and as the Vines had been hitherto fed on the top by mulching, &c., during the growing season, and covered up early, of course there was a good portion of roots near the surface, which, I need not say, were hard frozen. Not much relation between root and branch here thought I. I shall, therefore, be interested in seeing how the Vines succeed. I may just mention, however, that I am no believer in extremes of any kind. I would not pile high heaps of fermenting material on a Vine border, nor would I leave it bare as just named. I ought to add that these Vines always broke well, and furnished fine crops every season when protected. The above has been written believing we often learn as much from our failures as our successes. W. X. Y.

SAUCERS OF SOIL FOR FORCED STRAWBERRIES.

I REFER to this matter again just to assure Mr. Cornhill (p. 159) that allowing the plants to root through the bottom of the pot before they flower does not cause an undue "luxuriance of the foliage" at the expense of the fruit, as I am sure he will find out if he tries the plan fairly. It is not like treating the plants to strong doses of manure, for I only recommended sifted loam and sand with a sprinkling of Standen's manure, which consists of bone dust principally. Too much heat will cause an over-production of foliage more surely than anything I know, and not only in the case of Strawberries, but in that of some other fruits; but an additional rooting area cannot have that effect upon Strawberries in pots any more than it can upon Strawberries growing in the open ground. I find that young autumn-planted runners in a good, deep, well-manured soil always produce the finest fruit and the heaviest crops proportionately. My object in using saucers filled with compost was to save time in watering, which it does in our case, and to avoid using liquid manure which is apt to be spilled on the fruit and foliage by drip or otherwise, and also to cause a disagreeable smell in the house; whereas, the saucers of soil are perfectly inoffensive, the Standen's manure being quite inodorous when mixed with soil, or even when scattered on the surface of a pot. To me this appears a far cleaner and more convenient plan than watering the plants frequently with liquid manure of any kind. I was last year in a Strawberry house where all the plants had just received a dose of liquid manure made from drainage of the cow-houses and pigeries, and the smell was simply intolerable. I once knew a lady of high rank who would not taste forced Rhubarb after seeing how it was grown under pots covered with stable litter, till she had a forcing house, heated with pipes erected for the purpose; but I think a Strawberry house soaked with the drainings of manure is a still more objectionable feature of garden practice. According to my experience the Strawberry house is one of the places in the garden most frequented by ladies and gentlemen during March and April. They come simply to see the Strawberries growing. It is desirable that the house should be clean and free from offensive smells at such times.

J. S. W.

Pear, Leon Leclerc de Laval.—This is a good baking or stewing Pear, but worthless as a dessert fruit, although the late Mr. Thos. Rivers speaks of it as being often half melting and agreeable as such. This may be so in the soil and climate of Sawbridgeworth, but not here. I merely direct attention to it now for the purpose of pointing out its free bearing character, either in the form of pyramids or bush trees. We have had good crops from a bush tree during the last two seasons, and they keep well and are of good size. The tree is hardy and grows well here, and the fruit is fit for use from January till June.—J. C. F.

NOTES OF THE WEEK.

Camellias from New England.—Mr. C. M. Hovey, the well-known Boston horticulturalist, has just arrived in London, bringing with him some of his most remarkable gains in new Camellias, in the raising of which he has been for many years most successful. He has also brought a box of cut flowers of many of his own varieties, and these, which we saw in London the fifteenth day after they were cut in Boston, were in excellent condition. They were packed loosely in a cardboard box, there being five or six inches of shoot to each flower. Some of Mr. Hovey's new varieties will doubtless soon be seen in flower in this country.

Fuchsia splendens.—This fine Fuchsia is well grown, and flowered during the winter and spring months by Mr. Cannell, of Swanley. It is one of the best of Fuchsias for winter flowering, coming readily into bloom without much forcing. Indeed at all seasons of the year, under proper management, well flowered plants of it may be obtained. In habit it is graceful, whilst its Correa-like scarlet yellow-tipped blossoms are freely produced on every young shoot. In a cut state, sprays of it are very useful for small glasses or vases—a condition in which they last in perfection even in warm, close rooms for several days. Mr. Cannell has large specimens of this Fuchsia in flower at the present time in his nursery.

Spring Flowers.—I see in Somersetshire that hardy Cyclamens, slightly protected, are in flower. I have had the white Cyclamen hederifolium in a south corner, unprotected, in flower for the past fortnight; also Crocus Imperati, several sorts of Hepaticas and Galanthus Imperati, Violet Victoria Regina, and Helleborus colchicus and abasicus, are well in bud. Veronica Blue Gem I find stands the cold well, the temperature having dropped as low as 16° Fahr. Other kinds of Veronicas seem to have been cut back decidedly, the mean temperature for January being 32° Fahr. I have forgotten to mention that Daphne indica alba is also in bloom; notwithstanding the cold and snow resting upon it, the leaves are only slightly browned.—A. B. T.

Early Spring Flowers in Kent.—The frost having here relaxed its hold of the soil, spring flowers have made a sudden bound into full beauty, and, although the Snowdrop bears the Palm for chaste and quiet beauty, drooping its head as if to hide its charms, the Golden Aconite on the contrary spreads wide its yellow petals the moment the sun looks through the drifting clouds. We have here spring flowers such as these scattered in unlimited quantities on banks, under trees, and in semi-wild positions, and they seem to rejoice in being left undisturbed by spade or scythe.—J. G.

Cannell's Dwarf Ageratum.—This is the best Ageratum for pot culture which we have seen. In habit it is compact and branching, and plants of it grown in 5 in. pots make neat pyramidal bushes, that are masses of dark bluish-purple-coloured blossoms during the winter months, and form good associates for Primulas cyclamens and similar plants. In such company we found the other day a quantity of plants of it blooming profusely in Mr. Cannell's nursery at Swanley, where the stock originated.

Dracænas for Table Decoration.—Narrow-leaved Dracænas are found to be the best for table decoration, and when these combine a graceful habit with finely-coloured leaves they are doubly valuable. Amongst narrow-leaved kinds in Mr. Wills' nursery at Anerley may be mentioned D. Earsesi and D. Sydneyi, both of which have gracefully-arching and highly-coloured leaves. A kind to be sent out shortly, too, named D. Jaconda, promises to be one of the very best kinds in the narrow-leaved section ever raised at Anerley.

Fruit Prospects in Kent.—These, at present, are very favourable, for, in addition to a protracted spell of frost and snow, we have had scarcely a break in the clouds for weeks together; consequently buds of all kinds are still dormant. We can scarcely now have an early spring, and, considering that fruit trees have not generally been heavily cropped for some years, we ought, if the season prove at all propitious, to have an exceptionally fruitful year in store.—J. G. Linton.

Hardiness of Erica gracilis.—This pretty little winter-flowering Cape Heath has borne the Arctic rigours of the present winter with perfect impunity, planted out and quite exposed to the sea breeze at Sorrento Lodge, Dalkey, the residence of Sir Francis William Brady, Bart. The only trace of the effects of the frost is the slight discoloration of the young growth at the extremities of the branches, which are densely clothed with its pretty flowers, fresh looking as possible, and much brighter and more highly coloured than those on plants of the same growing under glass.—"Irish Farmer's Gazette."

Crotons in Winter.—A large house devoted to these in Mr. Wills' nursery at Anerley is just now remarkably attractive. The plants, which consist of almost every known kind, are grown in the form of

pyramids—a way in which they are much more graceful and ornamental than when tied and twisted into baloon shapes, as is too frequently the case with Crotons. The variety and beauty of colouring in the leaves, too, is such as is rarely seen in any one place, and at this comparatively flowerless season of the year the effect of such plants is more striking than at any other time.

Seeding Amaryllises.—These make a fine show just now in Messrs. Henderson's nursery at Maida Vale, where a large quantity of them are in bloom, and some thousands of them are coming on in succession. Amongst them we noticed several fine new kinds, notably one named Virgin Queen, which is almost pure white, and therefore a great acquisition.

Gloxinias at Anerley.—These are now coming freely into bloom in Mr. Wills' nursery at Anerley. Many of the flowers indeed have already opened, which is unusually early for Gloxinias. The plants on which they are produced are remarkable examples of good culture. They were raised from seed sown in the early part of last year, grown on, flowered, ripened off early, and started into growth early in winter. Plants of such easy culture as these can hardly be too highly prized, as, under proper management, they afford a variety of richly-coloured blooms from February till the end of summer. In another house some 10,000 or 12,000 seedlings are being grown on for use next year, a circumstance which shows how highly Mr. Wills prizes Gloxinias for decorative purposes.

Gardeners' Royal Benevolent Institution.—We understand that Mr. Sergeant Cox has consented to preside at the next anniversary dinner in aid of the funds of this institution, and that he has appointed Wednesday, the 2nd of July, for that purpose. The dinner will take place at The Albion, Aldersgate Street.

Prizes for Auriculars.—We are informed that Mr. W. J. Barnes, of Bristol, the maker of the patent square hand and cap glasses, proposes to supplement the prizes of the National Auricular Society's exhibition of April 22, next ensuing, as follows, viz., Class I, fifty plants, first prize, a 20-in. hand-glass; Class A, twelve plants, first prize, an 18-in. hand-glass; Class B, six plants, first prize, a 16-in. hand-glass; Class C, four plants, first prize, a 14-in. hand-glass; Class D, two plants, first prize, a 12-in. hand-glass; Class K, twelve plants, first prize, a 21 in. cap-glass; Class L, six plants, first prize, a 21-in. cap-glass; Class N, six plants, first prize, a 20-in. cap-glass.

NOTES FROM KEW.

Greenhouse Plants. The numerous and highly ornamental group of Rhododendrons which inhabit the high regions of Sikkim-Himalaya are now beginning to adorn the temperate house with their magnificent heads of blossom. The earliest amongst them is the Bearded Rhododendron (R. barbatum), so named on account of the long brown hairs with which the short leafstalk is thickly covered. The blossoms are large, of a very rich crimson with a dark centre, and are collected into dense globular heads, which terminate the branches. The Hairy Rhododendron (R. ciliatum), from the same region, shows the same peculiarity in the hairy leafstalk, though in a less degree; it is of dwarf habit. The flowers are 3 in. across, bluish-white, with striking brown stamens, and each head consists of six or seven blossoms. R. procer is a first rate shrub for forcing into flower early; it is very showy, dwarf in habit, and produces abundance of deep purple flowers. Gillies' Azara (A. Gilliesii), when not in flower, reminds one of some of the smoother leaved forms of the Common Holly; but the branches are tinged with red. The flowers are small, of a rich yellow colour, and produced from the axils of the leaves in oblong catkins 1 in. long. It is a native of Chili, where it grows at considerable elevations on the Cordillera of St. Iago, and forms handsome bushes from 10 ft. to 15 ft. in height. This extremely handsome shrub will also thrive and survive our average winters in the open air in some of the southern counties. Amongst the showiest of cool house climbers is the Toothed Hibbertia (H. dentata), a species with small oval leaves, possessing a ruddy tinge, and bearing a profusion of flowers 1 in. across, of a bright canary-yellow. The fact that it keeps in a flowering state during the greater part of the year much enhances its value. It is a native of New South Wales. The White-spotted-leaved Hamamthus (H. albo-maculatus) is a very desirable novelty from South Africa. The bulb measures 2 in. through, has green fleshy scales, and the leaves are three in number, leathery in texture, 9 in. long, 2 in. wide, blunt at the point, of a shining bright green, and studded here and there with white spots. The flower stem is short and stout, terminated by a dense head of pure white blossoms bearing yellow-tipped stamens. This is, we believe, one of Messrs. Henderson's introductions.

Stove Plants.—The Palm house is at present enlivened by several kinds of Francisca, small shrubs belonging to the Figwort family

and natives of South America. Amongst them are *F. eximia*, a kind with an erect, branching habit, lance-shaped leaves, and profusely studded with blossoms of a beautiful violet-purple colour fading to a lighter hue, each being about the size of a crown piece. *F. latifolia* differs from *F. eximia* in having broader leaves, smaller flowers, and a short calyx. The large-flowered kind (*F. macrantha*) is dwarfier in habit, and, as its name implies, it produces flowers of a superior size to the others. This, like the last, was found in Brazil. The value of these charming shrubs for stove decoration can scarcely be over-estimated, more especially as they are of such easy culture and flower so early, and by retarding the growth of some of them, a continuous succession of flowering specimens may be kept up for a long time. *Hebeclinium ianthinum* is a very handsome Mexican Composite, of bold aspect, having large, heart-shaped, coarsely-toothed leaves, and broad, terminal-clustered flower heads of a pale violet-purple colour, much resembling those of the common *Ageratum*. Though strictly a stove plant, this may be advantageously employed for the decoration of cooler houses, the plants for which should be grown in heat and introduced there when in flower. Two splendid species of *Strelitzia* have for many weeks past adorned the cool end of the Palm house with their gorgeous blossoms. They much resemble each other in general aspect, differing chiefly in the size and form of the leaves; both produce several flower stems that rise above the leaves and bear dense clusters of blossoms of most peculiar structure, of a deep indigo blue colour, accompanied by large-pointed floral leaves of a rich orange colour. Being of noble port, and producing flowers during many months of the year, they are highly desirable plants for greenhouse decoration, and are, moreover, very easily grown. Both are natives of the Cape of Good Hope.

Orchids.—In addition to those previously mentioned there are still several beautiful kinds that deserve notice, such as the large-flowered *Hyled Ocacidium* (*O. oculatum* var. *grandiflorum*), which is a little gem in its way, and certainly one of the handsomest of the family to which it belongs. Its flowers, which are large, have sepals of a greenish colour, the lip being nearly the size of a shilling, white, and copiously spotted with purplish-rose. The blossoms last a long time in perfection. It is of South American origin, being found growing on the trunks of trees in shady forests on the western declivities of Pinchicho. There are several other beautiful varieties of this fine epiphyte, all highly desirable for cultivation. *Dendrobium lateolam*, a native of Moulmein, cannot be considered a showy kind, as its flowers are wholly cream coloured and unaccompanied by a vestige of foliage. A far more attractive and graceful kind is *D. Pierardii*, the blossoms of which have a yellowish tinge with the inside of the hooded lip more or less heavily pencilled with carmine streaks. They are produced thickly on slender, pendulous stems, thereby rendering the plant admirably adapted for basket culture. This elegant kind is an old introduction from Barmah. The long-leaved *Lady's-slipper* (*Cypripedium longifolium* syn. *C. Reichenbachianum*), though not showy, is remarkably curious. It has very long, gracefully arching foliage, and sends up branching flower stems bearing blossoms 6 in. across; they have long, narrow, twisted petals of a pale green, and a lip 2 in. long of a green and dull purple colour. The rare *C. Lowi*, from Brazeo, is also finely in flower. Its spreading side petals measure 5 in. across, and are covered with short hairs, the outer half being of a violet-purple colour the inner greenish copiously spotted with deep purple; the lip is also of a purplish hue. One of the most desirable of the *Lady's-slippers* is the hybrid *C. Sedeni*, as it is remarkably floriferous, and has almost continually several expanded blossoms on it. Though its colour is not showy, the violet shade of the whole flower is very pleasing. It is a cross between the small-growing *C. Schlimi* and *C. longifolium*. W.

Ill Effects of Using Creosote Paint under Glass.—I notice that one of your correspondents recommends that the under sides of the laths intended for the paths in Vineries should be tarred. Last autumn, having to make, some I had all the laths painted twice over with creosote. This was done in an out-house, and they were allowed to stay there for three weeks so as to allow the smell to pass off. The effect under glass was disastrous. Grapes that were hanging were so flavoured as to be useless, the leaves were burnt, and several stove plants standing there lost all their leaves, and, in some cases, died. I offer this as a caution to others inclined to try it.—W. B.

Dielectric spectabilis.—If at this season, when this plant is pushing up its early growth, good strong clumps of it be lifted and placed in a very gentle heat, they will soon make beautiful plants for indoor decoration. Out-of-doors, a very sheltered position should be chosen for this plant, as, starting early into growth, it is liable to suffer from spring frosts.—J. G. Linton.

ANSWERS TO CORRESPONDENTS.

Finely-flowered Oncidium excavatum.—In answer to "An Amateur" (p. 173), allow me to say that, according to my experience of this species, I consider his plant to have bloomed unusually well. A small plant of it here threw up two spikes in November last; the larger of the two produced 280 blossoms, and the smaller one 190. It is quite probable that, had we removed the smaller spike in a young state, the larger one would have borne a much larger quantity of flowers. Does "An Amateur" use peat as his staple compost? If so, that may account for his obtaining so good a result. I find that this species does much better in peat than in anything else.—T. W. S.

Broken Mercury in Thermometers.—When thermometers get the mercury or spirits disarranged or broken up into several parts, there is no better way of rectifying them, than I am aware of, than taking the upper part of the glass in the hand and giving it a few sharp swings in a downward direction, the swiftness of which is generally sufficient to at once force the atoms together again. I have had many thermometers out of order, and I never get failed to rectify them in the above-named manner, and if your correspondent (p. 153) will adopt the same means, I have no doubt that he will be able to put the one he has, in a broken condition, into proper working order. If there be any difficulty with the index, a magnet applied to the tube just over it, and moved along, will cause it to follow, as it reaches the vacuum, where it will stop, a plan of setting that saves moving the glasses.—S. D.

Orange Trees.—The shedding of the leaves of Orange trees in the way stated (p. 153) does not mean that something has gone wrong with the roots, and, as these are most likely diseased or perhaps dead, it will be advisable to shake out the soil and substitute fresh material. That most suitable for Orange trees is a yellow, fibry loam that has been stacked for a few months; to this should be added about one-tenth or so of its bulk of thoroughly decomposed cow manure that has got dry enough to be rubbed up fine so as to admit of being incorporated with the loam, and to which, if not naturally a little gritty, some sharp sand ought to be added to keep the whole porous. Before repotting, however, a thorough examination of the roots should be made; all the decayed portions, if any, should be cut away, and, in case of disease or fungus showing itself, it will be best to give them a thorough washing by repeated dippings in a bucket or tub of water, for, unless the fibres are clean, it will be next to impossible to restore the plants to health again. With the roots overhauled in this way it will be necessary to reduce the top, which may be done either by a general shortening back or thinning out of the branches. This effected, and the potting complete, the next thing is to plunge the plants somewhere in a gentle bottom heat, or to place them in any forcing house or mild stove, where they can be frequently syringed overhead and have the benefit of a mild, genial atmosphere. In such a situation Orange trees soon break and become refurnished, but, till they get some fresh foliage, the soil must have but very little, if any, water, or young rootlets will not be able to take to it kindly. In order to lighten the work which plants thus treated have to perform, any blossoms that show themselves ought at once to be taken off, as they are a great tax, more particularly if allowed to set and develop into fruit.—S. D.

Names of Fruits.—*D. L.*—Your Apple is unknown in Covent Garden; indeed in its present condition it is indeterminate. Can you send us a fruit or two of it in a sound state?

Names of Plants.—*Capt. M.*—*Senecio Petasites*, sometimes called *Cineraria platentifolia*. *Anon.*—Your specimens, without fruit or flowers, are difficult to name, two, however, are recognisable, viz., the *Ruscus*, which is *R. Hypoglossum*, and the little *Barbican*, which appears to be *B. empetrifolius*. *W. C.*—*Asplenium falcatum*.

Books.—*Captain B. and R. F.*—"Hobday on Cottage Gardening," Macmillan, Belford Street, W.C.

Questions.

Magnum Bonum Potato.—Will some of your correspondents give their experiences with regard to this Potato? I had good seed, and was rewarded by a great yield; but the Potatoes are white, waxy, and watery—quite unfit to eat. A gardener 3 miles from here grew some with no better results, and they have been given to the pigs. Is this the fault of the Potato or the soil? and will it be of any use to give it another chance.—B. H. J. S.

Monstera deliciosa.—Would any of your correspondents kindly tell me how best to grow *Monstera deliciosa* for its fruit? Would a three-quarter span roofed forcing pit, 12 ft. 6 in. wide and 16 ft. long, with a back wall 8 ft. high, be suitable for the purpose? How should I plant and train the plant to the best advantage? The house would face the south.—E. G. L.

Camellia Donkelaari.—What treatment should be followed in the case of this plant with the view of ensuring its having the flowers bloated. A large plant of it in my possession has had them self-coloured for twenty-five years. Thinking the variety which I possessed might not be true, I obtained a plant in bloom, which, after the first potting, went back to the self-coloured flowers.—T. B.

Growing Plants in Fruit Houses.—Will "S. D." (p. 94) kindly state the method which he employs to have *Liatris*, *trigynum*, *Scierographis Giesbreghtianus*, and *Schizanthus Papiomaceus* well in flower during the winter months.—M. F.

ICE HOUSES AND ICE STORING

THE annexed plan of an ice house may possibly be of service to those who are contemplating the erection of such a structure. It will be seen that the "well" is entirely under ground. About most places it would not be difficult to find a spot where the whole building could be thus sunk, and being under ground it is less liable to be effected by variations

Ground plan of Ice Well.

Ground plan and elevation of small house over mouth of Well.

of temperature, and, moreover, the more effectually to guard against this, the "well" is constructed with double walls, between which a space is left to act as a non-conductor of heat to the inner wall from the outer wall and ground. The walls consist of 9 in. work, and the bricks ought to be laid in Portland or Roman cement. Some might think the inner 9 in. wall too weak, but if they reflect for a moment they will see that it is strong enough, inasmuch as the stored ice, unlike water or other fluids, has no lateral pressure, and, unlike the egg-shaped

Section of Ice Well.

"wells," the whole weight of the congealed mass presses on the bottom. The floor of the "well" ought to slope towards the centre, as shown in the annexed woodcut, in order that the water may be induced to pass quickly from the ice into a drain, where it may be found necessary to make one, as shown in the plan by the dotted line. The trap with which the drain is connected need not be very large; about 1 ft. square will be sufficient, and on the top of this an air-tight trap ought to be placed in order to keep back from the ice well any current of air which might enter it from the mouth of the drain. Over this trap a

few rough slabs should be placed, and over these should be put a covering of clean straw, which will prevent any sediment from getting to the trap and drain. The latter may consist of a 3-in. or 4-in. tiles, either of which will take away far more water than will drain away from the ice. Where, however, the ground is found to be gravelly or porous at the bottom of a well, I have no hesitation in saying that it is unnecessary to make any drain. A good large hole dug out and a few cartloads of rough stones packed into it, finishing off with a much smaller size, and laying on the top a good coat of gravel with the sand well taken out of it, will be found to be drainage enough in a porous bottom. It may be added that where the foundation is "sound" it is, in my opinion, quite unnecessary to concrete the bottom of an ice well. Turning now to the top, 1 is the ground plan of a small house to be built over the mouth of the well (2); 3 is a cross section and elevation of 1, showing a doorway in the roof into the well, through which the ice is to be obtained for use. On the ridge a beam ought to be placed lengthways, as shown in the section, to which a block and tackle should be fastened for raising the ice in buckets or boxes, and also for lowering and raising the person or persons who go down to fill them. The doorway will be found to be most convenient if made to open the whole length of the house, and it should form one-half of the roof; the other part of the roof would be best made of one large Yorkshire or Arbroath flagstone cut of sufficient strength to carry a few inches of soil on the top of it, as this side of the house, along with its roof and both the ends, could be easily covered out of sight. If the well were placed on a slope so that nothing would be seen but the front elevation (5) with its roof doorway, for the purpose described, and a small doorway (6) through which the well is filled from the shovels. It requires no barrowing along a passage, as close to the front of the little house a platform, either temporary or permanent, ought to be made, to which the ice is to be brought and pounded. This little door ought to be made as tight as possible to exclude air. A close-fitting trap-door ought also to be placed on the mouth of the well, which, by-the-way, can be filled to the top with ice. The little house should then be filled up with straw, the roof-door shut down, and all will then be finished. Thus far, I have tried to describe the accompanying plan of an ice-house, and to point out some of its advantages over those that are built about half out of the ground, and I think its superiority over either the "square" or "egg-shaped" forms will also be apparent, inasmuch as its storing capacity is greater than either of these, the circumference and depth being equal. It is drawn to the scale of 1-10th of an in. to 1 ft. As to the storing I have nothing to add to what Mr. Dennis recommends; as to the pounding of the ice, this can scarcely be too well done, but I do not believe in the straw up the inside of the house, and moreover a foot in thickness of straw all round the house lessens its storing capacity very considerably. I have a house to fill here, just such a one as that which Mr. Dennis describes, which I used to pack with straw, as he recommends, but I found the ice to keep no better, nor, in fact, not quite so well as without it. I store in this house sixty cartloads of ice every year when it is to be got, and it is consumed long before the summer is over. I also stack about 170 cartloads, which, when well covered, keeps for twelve months. This season there were about six loads of old ice when we began to put in the new. I may just add that I find light Oak mallets much better implements for pounding ice than sticks or clubs.

JAS. FAIRWEATHER.

Halston.

— Whilst thoroughly agreeing with Mr. Williams (p. 161) and others that ice may be safely stored in a "rough and ready manner," I cannot admit that it is a desirable method, unless the question of expense be paramount to all other considerations. Mr. Williams has said that he had nothing to add to my description of a well-constructed ice house (p. 59), and forthwith affirms that, as a rule, they are needless and often useless, and that the palm is to be bestowed on the "rough and ready manner." With regard to Mr. Williams' assertion that straw tied tightly in bundles is superior to the same laid in loose I entirely disagree. He says that "strawing ice wells is too often done in an ineffectual manner," but surely that is no reasonable objection, as those who have charge of the work

should see that it is properly done. When well done, it will be found to be far better than straw packed in bundles, and it will act exactly in the same manner, as far as drainage is concerned. The central column of straw seems worse than useless, unless, indeed, the suggestion that ice should be stored without being thoroughly broken is adopted, in which case it would certainly be necessary. Ice, if properly packed, will, in melting, form a cone for obvious reasons, and thus insure drainage from the centre. That ice houses or pits should be constructed as near the water from which a supply is to be taken as is possible is self evident, and, therefore, my suggestion that a convenient spot in the pleasure-ground or wild garden should be selected for the purpose, as, in the majority of instances, in places which have been laid out with taste and judgment a lake exists either in the pleasure ground or in proximity to it; and although filling icehouses is rough work the approaches to them are generally in the best condition for carting during hard frost. By the term pleasure ground I include woodland walks, drives, bridle paths, and all other positions which may be used for promenades. With regard to filling I maintain that ice cannot be pounded too small, as therein lies the secret of success in preserving it in suitable structures. The ice becomes a compact mass in a short time, and may, if desired, be cut out in solid blocks for use. That Wenham Lake and other ices are imported in blocks is easily accounted for, blocks being convenient for transport. Some hundreds of tons of it are generally unloaded within two minutes walk of this park; this ice is usually for immediate use and not for storing any considerable length of time. There cannot be the slightest doubt that the method described by Mr. Williams of filling ice wells with ice and water would recommend itself where practical, but I venture to ask how often would an opportunity occur in our variable climate of carrying it out; perhaps once in twenty years? I speak advisedly so far as the southern counties of England are concerned; those in higher latitudes may be more fortunate in this respect.

Southwark Park.

CHARLES DENNIS.

THE KITCHEN GARDEN.

POTATOES WORTH GROWING.

The information sought by "J. D. H." (p. 151) is identical with questions which have been put to me scores of times in a twelvemonth, and no wonder, for the immense number of Potatoes that have been brought before the public within the last dozen years, nineteen-twentieths of which are worthless to eat, is enough to perplex anyone who has not had an opportunity of trying them, or seeing and tasting them as grown in different parts, and from different soils throughout the country. I may here remark, too, that I do not consider a Potato worth growing that requires to be coaxed into a condition fit to eat, by only planting it on the very best picked soil. Any Potato that will not come good in quality on such land as "J. D. H." describes, and where he grew his Rivers' Ashleaf and Victorias so good as he says, is a useless lumberer of the ground. For many years I made Potato-growing a hobby, and a few years back, when quantities of the new varieties came out, I began to grow all of which I could hear anything like a favourable account. Every one of the American sorts I had enough of the first or second year, except one or two, which on good Potato land are just fairly good and nothing more, being always too soft for my liking; and by far the greater portion of the English-raised seedlings I found of a like description, although almost all will find some one to recommend them. With those who have space and care to grow a quantity of sorts for the sake of novelty, or to mark the differences in their character, and have plenty of pigs to give the bad ones to, there is no objection to growing any number of kinds, but to those who only want such of the best as will give a supply all the year round, the interminable number brought under notice is a positive nuisance. There is not one of the very early round sorts that I would now grow, for the reason that I never yet met with any equal to the Kidneys. If "J. D. H." has one good Kidney, such as Rivers', of which he speaks, Myatt's, Veitch's Improved, or Lee's Hammersmith, Dalmahoy, York Regent, and Patterson's Victoria, he has all that anyone can require who wants a good-flavoured, dry, mealy Potato that, when well boiled, shows, by its glistening look, that it is full of starch, and this, I think, is about

the description that comes up to the standard which most people like. There are some, I know, who say they prefer the soft ones that stick to a knife like a piece of new cheese. Those who like the latter have no difficulty now in meeting with plenty of such as will suit them.

T. BAINES.

Patterson's Victoria Potato, for which "J. D. H." (p. 151) substituted Climax, is one of the best Potatoes for winter use in existence, and I would recommend "J. D. H." to plant it again. Climax we regard as about one of the worst Potatoes for eating amongst all the American kinds; still, it is not naturally sweet, and probably those which taste thus may have been touched by frost. Rivers' Ashleaf, Gloucestershire Kidney, Early Mealy, and Patterson's Victoria are four excellent Potatoes for all seasons and situations. I do not think that it is generally known that Potatoes pretty smartly touched with frost will become as good as ever again if they are kept covered up and in the dark until they have become thawed. Some of ours were quite sweetened by the frost, but, owing to adopting the precautions just named, they have quite regained their natural flavour.

CAMBRIAN.

Winter Spinach.—When sown on a dry, warm border, about the middle of August, this is a valuable crop. It should either be sown thinly, or be thinned out at two operations—first, by drawing the hoe through it in the same way as turnips are hoed out; and then a short time afterwards, singling out the plants by hand to 7 in. or 8 in. apart. If the supply be required mainly for winter, it is better not to pick any leaves off in autumn, as that would, in a measure, retard and weaken the growth. If the plants have been allowed to grow on unchecked, there will be an almost unfailing supply in winter, which will prove invaluable in a season like the present. I have never known frost injure the prickly-seeded variety when grown on a warm, well-drained soil. Where green vegetables are much required, winter Spinach should be made a speciality, as it is sure to be in demand, and may be relied upon often when other crops fail in severe winters.—E. H.

Transplanting Onions in Spring.—Onions are often sown too early in autumn, and, as a consequence, are rendered more liable to bolt in spring. Some allowance should be made for latitude, but in most places the end of August will be early enough to sow Onions for transplanting, with the view of securing bulbs for summer use. I have at various times tried to ascertain, by experiment, if there were any advantage in transplanting at any particular period, or whether the autumn-planted crop, or those transplanted in February or March, did the best; and I have come to the conclusion that, except on dry, warm soils, the best time to transplant is in March, as early as possible after the first of the month. The removal from the seed bed to fresh, well-prepared land tends to encourage very rapid development and secures mild-flavoured bulbs. To obtain very large bulbs they must have plenty of space—9 in. or 10 in. square for each plant will not be too much, and this distance permits of the hoe being used freely in the early stages of their growth; but, if Onion beds are hoed after the bulbs begin to form, a very careful hand should hold and guide the hoe, as a very slight touch from the hoe or any other other implement may break the skin of the fast-swelling bulbs, and cause damage and deformity. In securing large bulbs for exhibition or other purposes, rich top dressings, accompanied by frequent waterings in dry weather, will play an important part, and must not be neglected by those who wish to excel. I saw very fine samples of a kind called Magnum Bonum at some of the exhibitions last year. It is globular in shape, and appears a remarkably fine variety, and likely to be a good keeper.—H. E.

Lettuces under Glass.—The glass roof in winter and early spring, whether it be a handlight, cloche, garden frame, or lights temporarily fixed, creates an artificial climate, and wards off, so to speak, the cold, cutting winds that usually do more havoc than still frosty air. The latter can always be rendered harmless by a thin covering of dry litter over the glass, which may remain on for weeks, if the low temperature continue, without the plants sustaining any material injury. It has been said that Lettuces do not force well. But how are we to define the term "forcing"? If it means simply forwarding crops by artificial means, then I say Lettuces can be easily forced; and I have always found that from this time onwards a little bottom-heat is of great advantage to them. Lettuce plants pricked out now on a bed of leaves, where a steady warmth can be secured for five or six weeks, will come on rapidly, and will probably fill up a blank and be highly appreciated. No doubt when, from a severe winter or any other cause, a scarcity of salading exists, a kind of express system of salad growing can be adopted by sowing Lettuces in boxes in a high temperature, and using them in a small state. The Early Paris Market I find the most suitable of the Cabbage kinds for this purpose, and any good white Cos follows well in succession.—E. H.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

NATURAL SITUATIONS FOR VIOLETS.

VIOLETS are ever welcome, and the demand for them is generally found to exceed the supply. Where wood and shelter in any natural form exist, there should be found Violets in abundance. The Mossy bank, the woody dell, are the natural homes of the Violet, and most readers of THE GARDEN will have vivid recollections of some such favoured spot, where they were wont in the sweet springtide to search for their flowers, laden with perfume and dripping with dew. Violets, shunning the free light and hot glare of the sun, retreat beneath the friendly shelter of some overhanging bough; there, nestling amongst the Grass, they are little affected by periods of drought, and grow freely and flower profusely. Where lies the difficulty in finding situations in pleasure grounds, where Violets would grow freely and increase in strength, extending themselves with each succeeding year? Such spots would not only be a source of interest in themselves, but would furnish such a quantity of bloom as would prove at times of great service. Some little care would of course be needed in the first instance, such as a little good soil in which to start them, and an occasional watering during the first season. There are some plants which never seem to fit into ordinary garden arrangements, and I have always considered that planting Violets in open flower-beds was inconsistent with good taste. They seldom look happy there, and often refuse to thrive. Violet culture in open situations requires experience, and a considerable amount of labour and attention, to bring it to a successful issue, especially in hot, dry summers; and the inexperienced, often failing to bestow the necessary care, are apt to make the complaint that they "cannot get Violets to last any time, the plants die off." Had some sequestered nook been chosen for them, screened from harsh winds and scorching sunshine, they would have shown their gratitude for the selection by an abundant harvest of bloom. In the more unfrequented parts of the grounds, where the scythe is seldom used, in the park and in the orchard, are to be found situations in which Violets would flourish and feel quite at home. They are impatient of confinement, but place them where they enjoy a free and constant circulation of pure air and they will grow and flower in perfection. Some of our newer kinds are strong growers and would undoubtedly naturalise well, but I do not see why even the most delicate should not be thus treated. I remember once admiring a large bed of that glorious double kind, so popular in France, called *Violet de Parme*. The plants had evidently escaped from some garden, and, running through a hedge, had established themselves in the Grass of an orchard, where they enjoyed the partial shade of some Apple trees. I never saw more healthy plants nor finer bloom than these produced, and their fragrance was something to remember. The hand of man had placed them in an unsuitable position, and they had instinctively discovered a new home for themselves. I have never forgotten that bank of Violets, and have never since seen anything so good. I do not think that Violets are very particular as to soil, so long as it is free and well drained; they never grow naturally where stagnant moisture exists. Soils of a loamy character, in which a considerable portion of decayed vegetable matter is present, are probably best, and when naturalisation is attempted on poor or sandy soils a top dressing of good mould might be annually afforded them, an amount of labour which they well repay. J. CORNHILL.

Byfleet.

Border Polyanthus.—These have stood the frost better than any other spring flowers, and, except the destruction of some of the old leaves, no harm has been done. Now nothing is showing bloom

earlier, all sorts, kinds, and colours are pushing into flower, but the earliest in all cases are the seedling plants of last spring. This is an indication that it is well to raise seedlings every year; the trouble of raising them is slight, and the advantage manifest. Not the least charm in the border *Polyanthus* is the great variety of colours which the flowers possess.—A. D.

HOW TO RAISE ANEMONES FROM SEED.

SUCH was an inquiry in THE GARDEN last autumn. The following method will enable anyone to raise them with complete success, provided the soil be suitable—namely, a moist loam. The seed may be sown at once. To save time I always sow it as soon as it is ripe, taking care only to select it from the very brightest-coloured flowers. First, as to preparing the seed; pains must be taken to separate it thoroughly. Spread a newspaper on the table, pour over it a quart of sand, or dry ashes, or fine earth; sprinkle the seed over this, and rub the two together till the separation of the seed be complete. As to the seed bed it need not be larger than 3 ft. by 9 ft. Choose the sunniest part of the garden. Dig and rake till the surface is very fine, tread it down, and give it a good watering. Wait until the surface is dry enough to scratch with a fine rake; sow broadcast, covering the seed about the thickness of a shilling; beat flat with a spade, and give a light sprinkling of water. Now comes the most important point in my method. Never let a ray of sunshine reach the bed; cover it with newspapers, spreading a few Pea sticks or something to retain the covering in its place. Keep the surface of the bed always moist. In about twenty days the young plants will begin to appear; when all seem up remove the covering, and no further care will be needed except watering. This must be strictly attended to, for if the bed becomes once thoroughly dry, the plants are apt, after forming small bulbs about the size of Peas, to stop growing, the foliage to die, and the bulbs to lie dormant for months, but if kept well watered through the summer they will go on growing all through the winter, and begin to blossom the following spring. Some young seedlings from seed sown as soon as it was ripe last year, removed to a box placed outside a south window, without any protection, are now (the end of Feb.) showing young blossom buds, and before March is out they will be in flower. The seedlings may either be left to blossom where they were sown, or be transplanted in September or October. Anemones are among the hardiest as well as the most beautiful of our hardy spring flowers. In spite of the late long and severe winter, a bed in my kitchen garden has never been without a few blossoms upon it. H. P. JESTER.

GERMINATION OF PRIMROSE SEEDS.

THE germination of seeds is, as your correspondent says (p. 161), an important subject not too well understood, and a matter in which one requires oftentimes to exercise patience. For instance, I have at the present time two kinds of shrub seeds, just appearing above ground, that have been sown as nearly as possible two years. In the ordinary course of affairs many people, not understanding their nature, would have thrown them away at least eighteen months ago, and blamed their seedsmen for sending them bad seeds. Your correspondent's account of his Primrose seed is a case in point; there is no ordinary everyday seed with which one requires to be more patient, and yet I should say that his plan of allowing the Primrose seed to sow itself amongst the weeds was one of the worst of all ways to get up a stock, for by this plan a large number would in all probability succumb to the exigencies of the situation. Notwithstanding this, he probably secured more than he would have done had he sowed the seed and kept it "nice and dry" till spring—another bad plan. The seeds of many kinds of Primula, if sown the instant they are ripe, will germinate at once, and make good plants before winter sets in. Others, if sown as soon as gathered, will remain in the soil till the following spring, and come up as regularly as Mustard and Cress (*P. japonica* for instance). In any case the seed is safer in the soil than in a paper bag, and much time is gained thereby, for, as in the case of *P. japonica*, if the seed be kept over till spring or until it has become thoroughly dry, it will not germinate for at least a year, and sometimes two; and the same holds good in the case of many hardy plants. The best plan is to sow at once as soon as the seed is ripe. Of course there are cases, as in those of seeds of easy germination, where this would not do, but in the case of all seeds where the period of germination is long or uncertain, sowing at once should be practised. A common error with sowers of Primula seeds is to cover them too deeply; as a rule they will come up much sooner if sown on a moist surface and kept so, than if they were covered, but the error is by no means confined to the seeds of Primula. Those of a large number of other plants are also lost through the same course of bad treat-

ment : almost any seed will grow on a uniformly moist surface, while many will not succeed if covered with soil.

Newry.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Winter Aconites and Snowdrops.—Much has been written respecting the undergrowth of Beech trees. Where this difficulty really exists, I would recommend the above to be planted thickly, as, when seen in large masses, as at this place, they are exceedingly pretty at this comparatively flowerless season. They will thrive even where Grass will not grow under the densest of deciduous trees.—W. G. B.

Hardiness of Terrestrial Orchids and one or two other Plants.—It will now be very interesting to hear of the success or failure of *Dia grandiflora*, *Orehis foliosa*, various *Cypripediums*, *Sarracenia purpurea*, *Darlingtonia californica*, and similar subjects which have of late years been planted out in bogs or peat beds in cool, moist situations. The past few winters have been exceptionally mild, but the present one has been severe, and yet I am pretty well sure that the snow covering which low-growing plants have had will have preserved many that would have perished if exposed to anything like the same amount of frost and cold cutting winds without the snow. It has always been a suggestive fact to me that, as a rule, aquatic and bog plants suffer less during frost than any others. During the past winter I have seen the Cape Apogonotet frozen hard in the ice, like a fly in amber in fact, for weeks, and yet the plant is now green and floriferous; *Sarracenia purpurea*, too, seems to enjoy a snow bath, being as fresh as ever. I am anxious about the scarlet *Dia*; perhaps Dr. Moore, of Dublin, or Dr. Wallace will give us some information respecting this anon.—B.

Japanese Methods of Packing Plants.—Those who have seen a shipment of Japanese plants unpacked cannot fail to believe that painstaking is a Japanese characteristic. Sometimes little baskets of split and woven Bamboo are used, in which the plants are closely packed, after having had Moss tied about the roots. The tops are protected by long Bamboo splints, and perhaps covered with straw matting and tied with straw rope. The most valuable plants are packed in long boxes, which outwardly present an appearance similar to those used in Eastern nurseries; but, whoever attempts to open them, will find a curiously elaborated system of wrought nails and almost unassailable fastenings. We do not think that the Japanese take sufficient care to secure their small painted labels to the plants. We have observed shipments in which half the labels were, on unpacking, found in the bottom of the box.

Lilies in Mud Balls.—Lilies from Japan usually arrive in perfect condition. This is owing to the method of packing. Instead of using sand, or sawdust, or dry Moss, the bulbs are "puddled," each separately in a thick clay mud, until each one is coated $\frac{1}{2}$ in. thick. Thin paper is, in most cases, then wrapped around to keep the mud from cracking off. These Lily mud balls are then packed in a box and some light material sifted in between them, and in this way they travel safely.—"Californian Horticulturist."

Hardiness of *Erica gracilis*.—This is not quite so robust a plant as the notice of it (p. 189) would lead one to imply. It is true that I have had it out of doors for two winters within a stone's throw of the sea, and without protection from frost, but between it and the sea blasts there is a bank of earth, which protects it from the fury of the winds. Thus situated, it has been more or less in bloom since Christmas. The snow has fallen round it, and, after a thaw, has been frozen into ice, but this bright little Heath has withstood all this hardship without injury. It is growing in a sheltered nook, protected from the north wind by a hill, and by the low bank which I have mentioned from the violence of the gales off the sea. *E. hymenalis* is also comparatively uninjured and in bloom out of doors, where it has been for two winters unprotected, except by a hedge, from the sea winds. There are many places in the south of England and Ireland much more favourably situated as regards shelter than this, and where, I have no doubt, many of the Cape Heaths would thrive well with suitable care. As to plants of any kind withstanding the full south-easterly gales off the sea, I know of very few indeed.—SARRENTO, Dublin.

A Handy Plant Frame.—Messrs. Ripplingville, of 118, Holborn, have invented a frame which is likely to be much used when better known by those who wish to raise their own plants in spring for window or garden decoration where room is limited. The frame in question is so simple in construction, that it cannot readily get out of order. In the interior is a strong galvanised iron tank, extending the whole length of the frame, and about two-thirds of its width, covered

with stoneware slates on which to place the soil or plunging material. The water in the tank is heated by a patent oil stove, which will burn without attention for twenty-four hours. The products of combustion do not enter the frame, but all the heat available is completely utilised; the stove is disconnected from the frame for trimming, &c. The tops of the frames slide off either way. This is very convenient for planting or removing the cuttings, or ventilating. The heat can be regulated at from 70° to 90° Fahr., which is a temperature high enough for propagating purposes.—S.

GARDEN LABELS.

No doubt many cultivators will readily endorse the remarks of "Brookhurst" (p. 145) with regard to the want of durable plant markers, and more especially is the want felt where there is the naming of a large collection of hardy perennials to be kept in an efficient state, as we all know that it entails a considerable amount of time and labour to do it thoroughly. Durability is the main point to be looked for in labels required for the outdoor garden, where they are expected to stand all weathers, and many kinds, both patented and unpatented, fail to give full satisfaction in this important quality. This is strikingly apparent after the recent severe weather, for those made of terra cotta are nearly all broken asunder and shattered, and those with porcelain faces, mounted on iron legs, are very much injured by the porcelain falling from the iron. Labels made of wood, whether deal or teak, are not durable, even when the lower halves are previously steeped in tar or creosote, unless they are made of such a size as to render them very unsightly. The most durable written labels I find to be those made of strips of zinc, with the names written on them with sulphate of copper, generally known as indelible ink. These stand for a very long period, and remain perfectly legible. Putting aside the matter of expense, of course, the most efficient labels are those of iron, carefully painted with several coats of white paint, and the names written in black. These are only suitable for public gardens, as, from their necessarily large size, they form a very objectionable feature in those belonging to private establishments. The suggestion of "Brookhurst" as to the desirability of having progressive numbers to correspond with a catalogue, instead of the written names, is not new, but, in my opinion, should be practised more extensively. As far as my experience goes, the best material for this mode is lead, with the numbers stamped in it. These will last for generations, and may be altered at will, simply requiring the number to be hammered out, or the portion containing it to be cut off. Their cheapness is another and not inconsiderable recommendation, for by using what is technically known as 4-lb. lead, i.e., 4 lb. to a square foot, the average market price being $\frac{1}{2}$ p. per cwt., and by cutting the labels in a triangular form, 6 in. long by 2 in. wide, which is quite large enough for ordinary purposes, 336 could be cut from 1 cwt., costing about $\frac{1}{3}$ d. each, and, when discarded, they may be sold as old lead for half the original value. If stouter lead, such as 6 lb. or 8 lb. be used, and the labels of larger size, the additional expense would be but trifling. A set of $\frac{1}{4}$ in. number stampers is all that is required, and a man may stamp several hundreds in a day. A stout pair of scissors to cut the lead to the required size is of course indispensable. It is a general plan for a private grower to arrange the numbers corresponding with his own manuscript catalogue, but I think it a pity that owners of large collections of hardy plants do not adopt an analogous method to that pursued by British botanists in arranging their collections of dried plants for purposes of exchange, &c., that is, they follow one recognised printed catalogue, known as the "London Catalogue of British Plants," where there is a number accompanying each name, and, therefore, specimens of each person's herbarium corresponds with those numbers, thus facilitating very considerably the usual tedious task of reference, exchange, &c.

W.

Distribution of Fruit Trees and Seeds amongst the Working Classes.—In the annual report of the Grantham Horticultural Society, the members are congratulated on the success which has attended the Society's operations. The result, says the report, may in some measure arise from the annual gratuitous distribution of fruit trees of the finest kinds amongst the working classes, to which, last year, gifts of thirty-five collections of vegetable seeds, each containing fourteen varieties of Sutton & Sons' stocks, were added. During the present winter a double distribution of trees (268 in number) has been made, Lord Brownlow and Sir W. E. Welby-Gregory having very kindly contributed to that special fund; and it may be added that the late Mr. Ostler contributed towards the seed distribution fund. The total number of trees that have been distributed is 818, and in this work the clergy and others have given very valuable assistance.

TREES, SHRUBS & WOODLANDS.

THE WOOD OF CONIFERS.

THE wood of most Coniferous trees may be distinguished even in the dark, at least, when recently cut, by its strong odour of resin. Moreover, its lightness for bulk serves to distinguish it from most kinds of timber in common use, and then a cross section of a trunk does not exhibit prominent medullary rays

Fig. 1.—A vertical radial section of the wood of the Spruce Fir. The longitudinal cells are studded with bordered pits, and a portion of the tissue of a medullary ray is shown in the middle of the section, traversing the longitudinal cells. Very much enlarged.

—lines running from the centre to the circumference—characteristic of the Oak and numerous other woods. Nevertheless, although inconspicuous, they are present; but Coniferous wood may almost invariably be recognised when highly magnified. A longitudinal section of the wood shows something like the accompanying figure, that is to say, the cells are studded with disc-like markings, called bordered pits. It should be mentioned, however, that this kind of marking, though characteristic of Coniferous wood, is not absolutely

Fig. 2.—Diagrammatic representation of the formation of bordered pits of the spruce Fir. The circles represent sections of bordered pits.

peculiar to it; indeed, similar markings are not uncommon in the tissue of herbaceous plants. These bordered pits originate from an unequal thickening of the cell wall. Spaces of the wall remain thin through very little of the thickening matter being deposited thereon. As the thickening of the other parts proceeds in two contiguous cells from the inside, it is projected from both sides of the thin part until the two projections nearly meet as an arch over the thin part. This occurring on both sides of the thin part separating contiguous cells, there are eventually two nearly enclosed spaces separated by the

original thin part. Should the wood cells lose their protoplasm (the active or vital substance), and the cells become filled with air and water, the thin partition is destroyed, and thus there is free communication, through the circular openings of the pit, between the cavities of adjoining cells. Seen from the front, the thin part and the thickened dome, with its orifice, appears as two concentric circles (fig. 2). Associated with this peculiar structure, in Pines and Firs, at least, is a remarkable substance, the value of which has only quite recently been determined. This is coniferin, which occurs in the cambium liquid or elaborated descending sap. It was first discovered by Hartig, in the Larch, about twenty years ago. It is obtained by boiling, filtering, and inspissating the sap to one-fifth of its volume, from which, after cooling, the coniferin separates in crystals, which have to be pressed and recrystallised from water or alcohol, with the addition of animal charcoal. Treated with chromate of potash and sulphuric acid, coniferin is converted into vanillin or vanillic acid, the aromatic principle present in the seed vessels of Vanilla, for which it appears to furnish a perfectly efficient substitute. During the past two years coniferin has been collected for this purpose in North Germany by hundreds of pounds. The price varies from 50s. to 60s. per kilogramme, and the operations of collection and preparation can be easily and economically performed by women. When the trees are cut down in spring or summer the branches are at once lopped and the trunk stripped of its bark; the trunk is then scraped with a sharp instrument and the sap is collected in sponges and expressed into pails. A healthy tree, of medium size, yields from 7 to 9 pints of sap, and each pint of sap contains from 100 to 125 grains of pure dry coniferin. W. B. HEMSLEY

ORNAMENTAL FORESTRY.

THE department of the planter's labours which more than any other displays his taste and judgment, is the selection and disc position of his single trees, and the arrangement of his small groups or clumps; for, while large masses of plantation should be characterised by simplicity, groups require variety, which may be obtained in one place by an admixture of species, in others by the arrangement of the trees in close or open order, or by differences of height, foliage, and general habits of growth. Wherever the area to be planted has been obtained from arable or pasture lands by the removal or grubbing of hedges and laying field to field, the necessity for planting single trees will seldom exist; here the difficulty will generally be so to thin out and group the remaining ones, as to eliminate their hedgerow character, and, at the same time, maintain the continuity of the plantations. As I have before remarked, the close-headed tree is by no means the most picturesque; its effect, like that of a very dense plantation, is lumpy. Those which give alternations of canopy and recess, and consequently of light and shade, are to be preferred in most situations, and for landscape effects trees with pendulous branches, twisted trunks, and contorted arms, as the Wych Elm; with sweeping and recurvate branches, as the Ash; with towering tops and wide-spreading and sweeping base, as the Silver and Spruce Firs; with a glorious mass of blossom, even though somewhat close-headed, as the Horse Chestnut; with overhanging and receding branches, as the Plane and Sycamore; and the Poplar, in some situations, are much more serviceable. The play of the branches in these gives endless varieties of light and shade, while very dense and close heads maintain nearly the same uniformity throughout the greater part of the year. Wherever dense shade is required, the planter can have recourse to the Beech, Spanish Chestnut, Oak, Elm, and Sycamore, all of which are highly effective, and upon good soils produce stately single trees. As subjects for landscape effects by means of pollarding, he has the Ash, Willow, Oak, Elm, Lime and Poplar; for giving seclusion the Spruce Fir and Scotch Pine, as well as the Larch, Willow, Poplar, and Birch, which may be cultivated with undergrowths of Holly, Yew, Hazel, Portugal, and Common Laurel, Dogwood and Box, or, if within the direct influence of the sea, the Elder and the Sycamore. For beauty of form combined with odoriferous qualities, there are the Birch, the Plane, and the quick-growing but short-lived Balm of Gilead Fir.

It is unnecessary, and, indeed, impossible, to particularise trees best adapted for standing singly in the various situations for which the aid of such ornaments is required. The planter must be guided by the character of the place as well as by the soil. To attempt to lay down rules without considering the real requirements of the situation would be like naming a tree for introduction to a landscape painting and at the same time utterly disregarding its accessories. Thus, the straggling ramifications of the Spanish Chestnut, which flourished upon the mountains of Calabria, where Salvator Rosa painted it in all its stages of decay, eminently fit it for the wild and desolate scenes into which he has introduced it, while the beautiful forms and the profuse foliage of the trees in the groups of Claude are equally well adapted to the rich balustrades which they overhang and the magnificent columns and porticos with which they are intermixed in his paintings. The Spanish Chestnut, as a single tree, is highly effective in park scenery, particularly where there are groups of Oak, with which it harmonises in colour, while the forms of its branches and the twisted trunk, the deeply-furrowed bark and the size of its leaves, produce the necessary variety. In July the heaviness of its head is relieved by the blossoms, which appear upon long catkins, and are followed by spiked clusters of the liveliest green, from which the seed is obtained in autumn. The Horse Chestnut has a growth so close and compact that its head would appear intolerably heavy, with its foliage in a round mass, quite destitute of lightness and airiness were it not for the profusion of pink and white flowers which adorn it in May. In a foreground this tree, even in full bloom, cannot be considered otherwise than as a glaring object; for, though each flower is intrinsically beautiful, the effect of the whole mass is heavy from want of variety. Its proper place is amongst a mass of other trees, to give density to distant scenery, or it may be serviceable to screen objects near at hand.

The Lime is seldom seen to perfection as an avenue tree, where it is generally clipped or elbowed and thus disfigured; but when allowed free growth it forms an elegant tree. Its warm tints give it a charm in winter, particularly in a snow scene. The variegations of the stem of the Birch, consisting of patches of brown and white intermixed with long stripes of a silvery lustre, the deep brown of its spray, combined with a lightness and elegance of form and graceful foliage, eminently fit it for the lawn and the park. In old age its bark becomes rough and furrowed, and generally uniform in colour throughout. The Acacia is too brittle for situations of great exposure, and its liability to accidents from storms makes it a tree not to be depended on for any length of time, either as a screen or an ornament. It should be planted only in situations fairly well sheltered. The beauty of its blossoms, the rapidity with which its quick growth repairs damage done to it by wind, and the luxuriance of its growth from suckers when planted near water are its greatest recommendations. The Plane and Sycamore are often highly picturesque in their forms of growth, and the effect is considerably increased by their habits of scaling or throwing off their bark in large flakes. Their leaves receive and reflect great masses of light and both kinds afford good shade, which, in the case of the Sycamore is almost impenetrable. The Walnut retains its leaves for so short a time that it is best planted singly or in groups unmixed with other trees. The warm russet hue which it assumes in May renders it highly effective as a contrast to the almost universal verdure which prevails at that season. The ramifications of its branches render it one of the most beautiful and interesting of deciduous trees, the blunted and partially-rounded ends contrasting well with the lighter and more graceful spray of the Beech and Elm. In the Beech the trunk is generally the most picturesque part, as it is often deeply fluted, while its smooth bark is generally variegated with irregular patches of Lichens. The beauty of its head is often marred by branches which shoot out in straight lines. A young Beech is, however, generally a free-growing and elegant tree. In its autumnal dress of sober brown and glowing orange, which often only partially hides an inward wealth of lingering verdure, it presents a contrast to the Horse Chestnut, upon which the outermost leaves are the last to turn yellow and drop off.

The pendent branches of Wych Elms sometimes give to their heads the most fantastic forms, producing the perfection of jutting promontory and reeving cove, aspects which are frequently heightened by accidents to the branches in consequence of their brittleness. In the production of masses of light and shade the Common Elm far surpasses both the Oak and the Ash. In situations where this tree either connects other plantations or breaks their abruptness it harmonises better than almost any other with the Fir tribe during the summer, and with the orange of the Beech and the russet of the Oak in autumn. Upon a good and suitable soil it also rises into a stately tree. In the Ash beauty of foliage generally accompanies elegance of form. The way in which the branches first start off with a growth close to the stem, then gradually assume a graceful sweep, often ending with a recurvate form, is highly effective. When fairly sheltered, the Ash retains its leaves of a lively green in a mild autumn longer than most other trees. It is seldom very handsome in old age, as the new growths which start from broken branches and from the trunk after accidents do not harmonise with the ruin.

The Oak combines in itself stateliness of form when young, with majesty in its prime, and grandeur in old age. Its head is fairly light and open. When the young tree is unpruned, the branches appear to divide the trunk instead of merely springing out of it, and this gives it a distinctive character. Whether as the aspiring young tree, the king of the forest or the "unwedgable and gnarled Oak," this tree everywhere commands admiration. After a severe winter and a cold spring, the Oak comes into leaf before the Ash, but during a warm spring the Ash, which is shallower rooted, sooner feels its influence and bursts forth first.

A. J. BURROWS.

GLOSSY-LEAVED LAURUSTINUS.

(VIBURNUM LUCIDUM.)

OF the numerous varieties of the *Laurustinus*, this has the boldest foliage and the largest flowers, and it has altogether a more robust habit of growth than the ordinary varieties. At the moment of writing I have not fresh specimens of this fine *Laurustinus* before me, but among the numerous dried specimens of *Laurustinus* in Kew herbarium, there is one of *lucidum* collected by the late Dr. Bromfield in the Isle of Wight. It is so distinct from all the others in its larger flowers and smooth shining leaves of great substance, as to at once attract the eye. Bromfield collected it "from a finely flowering and very large bush in the grounds at St. Clare, Ryde, February 5, 1846." There it appears to have developed its full beauty, and I believe this shrub can only be recommended for the southern and western parts of the kingdom. My experience of it in the heavy soil of the weald of Sussex is that it is less hardy than the common *Laurustinus*, but on the chalk it succeeds perfectly. In fact, all the varieties appear to flourish well in chalky soil, and I never saw more floriferous and healthy examples than those growing almost on the bare chalk near the sea in the south of England. Loudon says of this variety, "When the winters are sharp, the flowers are killed, and never open unless they are sheltered." He adds that it is a native about Algiers and on Mount Atlas, which would account for its being tender. With regard to its native country, Lawson is probably right, for the wild specimens in Kew Herbarium, nearest this, are from Morocco. This variety is also called *grandiflorum* in some gardens. It is noteworthy that a shrub which has been cultivated in British gardens for a century or more should remain comparatively rare, and it is also singular that it should never have been figured before. Probably this is not only because it is not so hardy as the common *Laurustinus*, but also in part due to the fact that it is not so easily propagated. For several reasons, independently of its constitution, this variety should nowhere altogether replace the ordinary one. It does not usually flower so freely, neither does it flower so early, and its flowers, though larger, are not so suitable for cutting, on account of the stoutness and rigidity of the branches. Again, it is of taller growth, and does not form the neat, dense bushes of the ordinary *Viburnum Tinus*. The specimen from which the annexed illustration was prepared was supplied by Mr. Scott, of Merriott, Crewkerne, Somerset.

W. B. HEMSLEY.

LARGE GLOSSY-LEAVED LAURUSTINUS (*VIBURNUM LUCIDUM*).

CAMELLIAS OUT-OF-DOORS.

I THINK it will probably be found that Camellias are hardly less hardy than the common Laurel in any part of the country, but whether they will bloom successfully, or with any degree of certainty is another matter. I presume the prospect of flowers is the only inducement to make the Camellia an outdoor shrub, for there are plenty of other shrubs that are quite as handsome and more readily procurable for forming shrubberies. We have a plant of the old single red variety that has been growing outdoors here for forty years or more. Whether it has at any time been killed down or cut down I do not know, but it seems to have been cut back once to near the ground. I have, however, known it for fourteen years, and it had not been meddled with for a long period before that as far as any one can remember. I moved the plant about ten years ago to an exposed south border, and it is now a squat-headed bush about 5 ft. high, and always sets a great quantity of buds, which expand freely after mild winters. The plant is in perfect health at the present time, and does not appear even to have been browned, as some of the Portugal Laurels have been. I doubt, however, if the buds will expand, as they appear to be black in the heart now, though, to all appearance, right enough outside. I believe this same plant was mentioned by Harrison, some forty years ago, when he was gardener here, either in the "Transactions of the Royal Horticultural Society" or in the old "Floricultural Cabinet," of which he was the conductor, and then, as now, the hardiness of the Camellia was under discussion. When I was at Drumlairig Castle there were several Camellias of a good size planted against a north wall and in good health, though, so far as I remember, they did not flower during the five years I was there. They were only protected by a mat in winter, and the thermometer frequently dropped during hard weather nearly to zero. In Dorsetshire, I am told, the trees frequently bloom pretty freely, though the frosts are severe enough in winter sometimes to kill the Broccoli in the kitchen garden quarters. A few years ago I saw a shrubbery of Camellias in a garden not far from Bournemouth. I think there can be no doubt about the hardiness of the plant, but the question is, Is it worth while planting it out-of-doors except in situations where it will flower freely?

J. S. W.

—It would be unfortunate if the remarks made (p. 177) upon the present appearance of Camellia buds on plants in the open air, should deter any one from planting these noble and singularly hardy ornamental shrubs. That the flower buds may after the recent severe weather be damaged to some extent there can be little doubt, but then how many other hardy shrubs have suffered in a like degree. Have we not often had seasons, when even the hardy Rhododendrons have had their flower-buds almost destroyed, and yet who would make this an objection to planting them as much as ever? Most people who have Camellias in the open air, find that they flower freely and well five out of every six years, and that the plants are perfectly hardy.—Indeed, much harder than many shrubs that make their new growth early in the year. Rhododendrons, Laurels, and many kindred shrubs often have their young shoots cut back by late spring frosts, but this does not happen in the case of Camellias, simply because their young growth is made later, and is thoroughly ripened and seasoned by the summer's sun. A free exposure to sunshine is not essential; indeed a little shade during the hottest parts of the day is rather beneficial than otherwise. The greatest enemy to the flowers is fierce winds, which break them about; but then all flowering shrubs are subjected to the same danger when storms abound. Any one planting out Camellias for the first time, will do well to plant first some of the commoner kinds, and in somewhat sheltered situations; then, when these are seen to thrive, continue with more valuable sorts, and extend the radius of exposure. In this way both experience and confidence are gained. The soil should consist of a good admixture of peat and a little rotten manure, but it is not desirable to excite rank growth.—A. D.

—I have seen a very fine specimen of the old double white Camellia in front of a private residence in High Street, Battle, beautifully in flower, the blooms being quite as perfect, as regards form, as those grown under glass. It would be best to plant Camellias against a wall in situations where they required protection, as in that case it could be more effectually applied.—A. H., *Ragley*.

RABBIT-FENCES AND FRUIT-TREE PROTECTION.

I AM afraid we rather underrated the rabbit's powers of leaping, a question which determines, to some extent, what sort of fence will be required to keep them out of places where they are not wanted. I have seen a rabbit jump up upon the top of a stone fence 3 ft. high, and jump down on the other side, and it had not been driven or frightened in any way. We have had considerable trouble with them

here, both in the woods and pleasure-grounds, and to test their abilities in getting over a wire fence, I enclosed some young wild rabbits about a month old, and just tame enough not to be frightened at any one's presence, within a ring fence of galvanised wire, 2½ ft. high, set up with stakes on the Grass in front of my house. They were hardly two hours in this before they were out again; they were put back over and over again, always with the same result. They scrambled up the wire like a cat, and let themselves tumble over on the outside. Whether rabbits would act in the same way, if they wanted to get to a plant, I do not know, but it is quite probable they would, if pressed for food. The suggestion of "A Soldier" (p. 168), to lay a piece of wire flat on the ground in erecting wire fences is a good one, but it is better simply to bend a piece of the upright sheet of wire out than to put down a separate piece, as holes are apt to be made at the junction. Such a fence is better than a stone wall. Rabbits are sometimes very troublesome in orchards during severe winters, gnawing the bark off the stems of the trees and killing them. In such cases, when the trees are not over numerous, wrapping the stems round with paper, just a little higher than the rabbits can reach by standing on their hind legs, will be found an excellent and perfectly effectual preventive. The paper should be tied on pretty securely, otherwise the winds and rains will tear it off.

D.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS

Gorse or Furze.—Land intended for Gorse seed should be prepared much in the same way as Turnip land, that is, deeply stirred and finely pulverised; it should also have a dressing of good lime compost or a little well-rotted manure where a quick growth is desired, though it is a plant that will eventually flourish even upon a poor soil. From the middle to the end of April about 4 lb. of good seed per acre may be either sown or lightly drilled in; this will be found sufficiently thick either for cover or for cutting as food for stock. Where Gorse is intended to form a hedge about 1 lb. of seed to the 100 lineal yards may be sown upon the top of a well-worked ditch bank. This plant is more permanent if it be not allowed to seed, and the best time for trimming it is directly after the flowers are shed, generally about the middle of June. During the severe weather of the present winter rabbits have in many places made great havoc among the young Gorse of last year's sowing.—A. J. B.

Sowing Broom Seed.—Most kinds of Broom, but more especially those of the largest growth, known as Portugal Broom, flower early in May, and ripen their seeds by September; and the sooner these seeds are committed to the ground after they have been gathered, the better plants will they make the following summer. They may, however, be sown with Gorse in the spring, or transplanted amongst it as seedlings. It is difficult to say in what proportion these seeds should be sown together for ornamental purposes, but we would recommend a trial of 1 lb. of Broom to 3 lb. of Gorse.—A. J. BORELWS.

Spruce Fir Timber.—In alluding to useful Conifers (p. 143) "S. D." speaks of the Spruce as a worthless timber tree. This surely cannot apply to the Norway Spruce! The Spruce will thrive and produce useful timber on boggy ground, where few other trees will succeed. As a shelter or nurse tree, too, at suitable elevations, it is of great value. In Scotland and in Ireland the thinnings of Spruce sell as readily as those of Larch for fencing purposes, and for pit props. For roofing farm buildings Spruce has long been used in Scotland. I need hardly speak of the value of imported Spruce timber for scaffold poles, spars, masts, white deal, Baltic deal, &c.—CHAS. McDONALD, *Garden House, Stokesley*.

Cercidophyllum Japonicum.—This very rare and choice tree was, as far as I can learn, first introduced to America by Mr. Thomas Hogg, who sent it from Japan to his brother, Mr. J. Hogg, of New York, at least as early as 1863. This very tree stands in Mr. Hogg's garden at Harlem to-day; and its ornamental value, as there indicated, is very great. The outline is pyramidal and the foliage rich, glossy and beautiful, resembling the heart-shaped leaves of the Japan Judas tree, only smaller. Indeed, we may reasonably expect that the attractions of the Cercidophyllum will, in time, gain for it among deciduous trees a reputation similar to that possessed by the Japan Judas tree among shrubs. At present, however, it is almost, if not entirely, unobtainable in this country. Practically it cannot be grown from cuttings, and little or no seed seems to have been sent from Japan. An anomalous tree, its relations with other plants are peculiar; for, though said to be of the Magnoliaceae, it cannot apparently be grafted on any stock known in America.—"Rural New Yorker."

PLANTS AND FRUIT FOR MARKET.

CURCULIGO RECURVATA.—This is a plant which sells readily in the market, but at present it is rather scarce. It will, however, in time probably be one of the most extensively cultivated of ornamental-foliaged plants. Its leaves are beautifully recurved, bold, and striking, and well-grown plants of it in 6-in. pots, furnished with from six to ten leaves, make admirable subjects for vases, dinner-table, and similar decorative purposes. Its enduring properties constitute one of its chief advantages. There is also a variegated variety of it, but this is more tender than the type and, as yet, too expensive to be remunerative. Indeed, it is a question if ever it will be appreciated as much as the green-leaved form. The *Curculigo* is increased by means of offsets, which are thrown up from the roots of old plants. These are torn off, placed singly in small pots, and plunged in a brisk bottom-heat; when well rooted they are potted, after which water (overhead and at the roots), heat, and air are all that are required in order to induce the plants to grow rapidly. In eighteen months excellent marketable specimens are obtained, and sometimes in much less time, and, as the plants take up comparatively little room and fetch high prices, their culture is remunerative. Any good soil, well drained, suits the *Curculigo*, but rich fibry loam mixed with leaf-mould or rotted manure and a little road or silver sand, makes the best compost for it.

CROTONS.—These are good market plants, but they are not generally grown to the same extent as *Dracænas* or India-rubber plants. Some of the old kinds, such as *C. variegatum*, *C. undulatum*, and *C. Weismanni*, are those principally grown at present, but there has of late years been so many new and attractive kinds with long, gracefully-drooping leaves that we may expect *Crotons* soon to rank among the most popular of market plants. They are increased by means of young shoots, the points of which have been previously pinched out and have again started into growth. In this way, bushy tops are obtained, which, when taken off and placed in small pots, soon take root, and in twelve months make handsome little plants. Heat and moisture are the chief essentials to success, as, in order to have well coloured leaves, too much heat can scarcely be given them, provided moisture is supplied accordingly. *Crotons* are, however, not good room plants, as the effects of gas soon cause them to shed their leaves.

FICUS ELASTICA.—Of all plants grown for their foliage for market purposes this is the most popular. It is the best London window plant in existence, and a plant which will grow and keep healthy in the same pot for years if well supplied with water. Nearly every florist around London grows as many plants of it as he has room for, and yet it keeps up its price in the market. It is propagated by means of young tops of growing shoots, which are taken off and struck in the same way as those of *Dracænas*, old plants being generally grown to provide them.

YELLOW-FRUITED CAPSICUMS are now grown for market purposes, and sold for decorative purposes alone. The seed is sown early in spring, say in March, in pans or shallow boxes, placed in a gentle bottom-heat. When up, the seedlings are potted and grown on in a warm pit or frame. They fruit ten weeks after sowing, and have a very effective appearance, especially when associated with scarlet-fruited kinds. When grown close to the glass, and allowed plenty of air, they form dwarf, shrubby plants, 12 in. or 18 in. high, each bearing from thirty to forty shining yellow fruits, which last in beauty for several months.

CYPERUS ALTERNIFOLIUS is also a favourite market plant; it is easily increased by division of the roots, and it can also be raised from seed. Heat, rich soil, and water are its chief requirements. The variegated kind is seldom seen in the market.

Myrtles, Scented Verbenas, Ardisia crenata, and Coleus are all grown for market, the two former being always in demand.

GREVILLEA ROBUSTA.—This is a capital market plant, and one which is much valued for room or table decoration. It is raised from seeds imported from Holland, which, if obtained new and good, soon germinate. It is sown in heat early in spring, and the plants are potted on until they occupy 6-in. pots, when they are placed in an intermediate temperature until they attain a height of from 18 in. to 20 in., when they are sent to market. Seed sown at the time named produces good marketable plants in autumn, which is the time when they are most plentiful.

Hardy Shrubs.

Green-leaved *Euonymuses*, *Yews*, *Retinosporas*, *Arbovitæ*, and many other compact-growing shrubs are sold by thousands for window decoration during winter. The Golden Yew is a favourite plant, as are also the green and golden-leaved *Thujas*. Most of these are imported from France. Many thousands of *Thuja aurea* are, however, raised from seed yearly, and one grower near London has a method by which he can get the seeds to germinate in a few weeks. When once up the plants grow rapidly, and, by being potted on, soon make handsome little bushes which never fail to find a ready sale at remunerative prices.

EUONYMUS JAPONICUS and its golden variegated variety are grown by the thousand in cold pits, and good, bushy plants of them in 5-in. pots fetch from 12s. to 18s. per dozen. *E. radicans* is also grown for the beauty of its foliage. *Euonymuses* are easily propagated, and soon grow into saleable plants. They withstand the dust and smoke of London better than most other plants, and on this account are readily bought up for the decoration of balconies and window-sills. Cuttings of them strike readily, and, if grown on in a warm house or frame, soon become bushy little plants.

ACUCUAS.—These rank amongst the most important plants in the outdoor department, and many valuable seedling varieties of them have been raised by market growers. They are chiefly grown in pots, and by introducing male plants amongst them they become loaded with large clusters of brilliant scarlet berries. The variegated form, too, may be found heavily laden with berries, and at Christmas time such plants find a ready sale at high prices. When standards are required, grafts of a free-fruited kind are placed on stocks of the common variety, grown to the desired height. By this means handsome plants with fine round heads from 2 ft. to 3 ft. in diameter, and studded with scarlet berries, are rapidly obtained, and fetch from 10s. to 15s. per pair in the market. Young, dwarf plants of *Acucas* are obtained by pegging down on the ground branches of established plants; in this way they soon strike root. They are then severed from the parent plant, potted, and placed under cover to come into bloom in order to be fertilised. After the berries are well formed, the plants are taken into a warm temperature in order to get the berries well coloured.

Fruit.

The demand for fruit in this country has during the past few years increased to an enormous extent. Both for hardy and indoor fruits there is always a ready sale, and,

notwithstanding that the quick and cheap means of transit enables Continental growers to send their produce to London in such large quantities and in such good condition, the extension of fruit culture in England is on the increase. It would be difficult to form any estimate of the amount of fruit consumed yearly in London alone; but that it must be something enormous we may judge from the fact that nearly £6,000,000 is yearly sent out of the country for foreign fruits. If we suppose that London consumes only one-twentieth of this, it costs us £300,000 to supply the metropolis with fruit, irrespective of what we ourselves produce. Forced fruits from France and the Channel Islands come at times to our markets in such quantities as to render English produce anything but remunerative, and it is only by attentively watching and ascertaining the requirements of the markets at all seasons of the year that our indoor fruit growers can make that industry profitable. The price paid now for fruits deviates but slightly from that paid half a century ago; although the quantity which we receive is fifty times greater, yet the demand has increased accordingly, and thus the price has been kept up. Much has been written on the subject of the extension of fruit culture in England as a profitable industry, and, whilst some have recommended our railway embankments, which, at a rough estimate, represent nearly 200 square miles, to be planted with Apple trees, Pears, or Cherries, the fact seems to be overlooked that in a plentiful fruit-season the grower's profits are almost trifling compared with those realised in a year when the crop is only moderate. It has been said that a profit of £100 per acre can be obtained by fruit culture, and that such an amount has sometimes been realised there can be no doubt, but seldom of late years has that been the case. Even in a plentiful year hundreds of bushels of good Plums, Apples, and similar fruits are allowed to rot because the market is so well supplied from abroad that they would not pay for the gathering.

Early Plums have been tried on a large scale by several growers near London, but, when we look at the present state of the market, this seems a bad investment, because, in the first place, the blossoms of early Plums are fully expanded just when spring frosts, of which we have had ample experience during the past few years, overtake them, and the consequence is only a partial crop. Then, in the second place, suppose the crop to be a plentiful one, the fruit is ripe just at the time when the "glut" comes from abroad, and the prices are, therefore, low. Now, if late Plums, to come in after the bulk of the foreign produce is over, were grown, there would be a good chance of profit arising from their culture, because the blossoms would be more likely to escape spring frosts, a better crop might be depended upon, and the fruit, being fresher and in better condition than that from abroad, packed in barrels and tubs, would meet with a readier sale at remunerative prices.

To Apples and Pears the same remarks, to a great extent, apply. When, in plentiful years, there is a "glut," the price obtained hardly repays the cost of gathering, storage, and cartage; therefore, the best fruits are kept back until later in the season, when sound-keeping Apples and Pears fetch fairly good prices. It has been stated that fruit culture ought to prove more profitable than meat culture. "In order to fatten a bullock," it is said, "we require at least the produce of 2 acres of good land for three years, after which the animal is worth from £20 to £30, while, on the same ground, we could have grown at least £100 worth of vegetables and fruit." This statement, however, fails to fairly represent the case. In the first

place, the expenses connected with 2 acres of Grass land for bullock feed would be little or nothing compared with those incurred in the production of fruit and vegetables on the same space, and the cost of marketing the two commodities would be also greatly in favour of cattle feeding. If farmers who fatten bullocks were to devote the ground on which they feed them to vegetable and fruit culture, and it came a good year or two for these crops, they would certainly have cause to repent the change which they had made. Fruit trees, too, it must be remembered, take several years to become established. If, as has been stated, £100 per acre can be gained by fruit culture, it is surprising that so little fruit is grown. I have no doubt that if ten people were to start fruit and vegetable culture on a large scale for, say, ten years, they would realise good profits, but I am persuaded that if 10,000 people started in the same kind of culture, the result would be a failure. If, in the neighbourhood of towns, the public could buy direct from the growers, we should have good results, but, where the produce has to pass through several hands, just the reverse is the case. Fruit culture, as it now is, pays fairly well; but, if it were greatly extended, prices would become so low as to be unremunerative. C. W. S.

THE FRUIT GARDEN.

HEAT FROM FERMENTING MATERIALS FOR VINE STARTING AND FORCING.

ONE can almost fancy some cultivator of the very old school exclaiming—why, what does that mean? heat is heat! What matters it how produced, or where it comes from? Stay, was the heat of flues equal to that of hotwater pipes? Well, for some purposes, perhaps better, when we had it pure and without smoke and sulphur. Just so, and I am willing to admit, to cut the matter short with our older cultivator, that I have seen as good Grapes grown by the heat of flues as by that of hot water or any other mode of heating. Smoke and gas-light flues surmounted or crowned their whole length by evaporating troughs of water-tight cement, gave out a heat at once pure and genial, soft and sweet. But then there were serious risks, for smoke has a wonderful power of escaping through the tiniest flaw in flues, whereas it often seemed as if sulphurous gases discharged their broadsides into the houses through the bricks themselves. Hot water is pure and inoffensive, neither can it subject the pipes through which it passes to such extremes as to burn or change the chemical properties of the air, and hence it may be described as the most perfect mode of heating that has yet been invented. But, nevertheless, the heat evolved during decomposition is undoubtedly better for some purposes than that obtained from any other source. It is also so cheap that it may in fact be said to cost nothing. Of course there is the labour and expense of purchasing, or, at least, collecting and carting manure and leaves, Cocoa-fibre refuse, tan, sawdust, or other substance that yield considerable heat during the process of decay. But the products, that is, the manure left as a residuum, pay the cost of labour and material, and the heat may be said to be presented free of cost to the cultivator. Decomposition is not only the cheapest source of heat but the heat so generated is of the highest quality; it is genial and feeding, as well as warming. There is no known means of generalising the air of houses so effectually as the introduction of a mass of manure and leaves on the floor and bed of the house. The whole decomposing mass raises and distributes moisture in the finely-diffused form of visible or invisible vapour. It is probable that this is one great cause of the superiority of the heat of decomposition. Many of the means of generalising the atmosphere of Vineries or other hothouses may be described as far too gross and ponderous, the latest teachings of science being to show that the leaves of plants do not absorb water. Be that as it may, it is certain they cannot absorb the huge drops

which are frequently applied to the delicate leaves of Vines through the rose of a syringe. In striking contrast to this is the gentle vapour that rises softly from the surface of a decomposing mass of leaves and manure. The constancy of the supply of vapour, too, adds to its potency and its value. Most modes of vapourising the atmosphere of hothouses are more or less fragmentary or intermittent. They are apt to be neglected just when attention is most needed. The vapour may be said to vibrate, as it were, between the extremes—dryness and saturation. By the use of hot manure or other material, the two important processes of warming and vapourising are linked together by natural laws, and the one cannot proceed without the other. Every degree of heat raises its proper modicum of moisture with it; thus the whole air of the house is genialised in the most efficient manner. Probably, too, the wide area of the evaporating surface has something to do with the greater efficiency of the mode of heating rendering the atmosphere genial. It is customary to cover a large proportion of the floor of Vineries with decomposing matter; this entire surface becomes a large evaporating pan of the most approved sort, neither too hot nor too cold, under good management. Much evil has been wrought by evaporation being overheated by fires, &c. Tender leaves may enjoy vapour but a very little steam fetters their functions or destroys their life. An excess of vapour may also arise from decomposing materials if they are used in too rank or too moist a condition; but, properly sweetened and all excess of moisture sweated out before being introduced into Vineries or other houses, the vapour and heat alike will be sweet as a Nut. Then such heat is feeding as well as soft and genial; even the vapour is more or less charged with carbonic acid gas and ammonia and other plant food, and the heat diffuses these through the atmosphere, lifting the heavier gas by its buoyant power and bringing it into direct contact with the stems and leaves of the hungry Vines, and these immediately turn them to account.

No other source of heat within reach of the cultivator thus simultaneously feeds and also warms plants. It may be fancy or it may be fact, but it almost seems as if one could see Vine leaves consume the food thus offered them; the leaves are larger, greener, grow faster, as a rule, where decomposition is employed as a source of warming. Not only this, but the Vines break more kindly and with greater regularity and stronger vigour. So generally is this admitted, that many cultivators use a bed of decomposing matter merely for this special purpose; as soon as the Vines fairly break into leaf and shoot the manure is removed. The mere fact, however, that such materials furnish the plants with a full supply of gaseous food suggests the importance of using them with caution and skill. An excess of carbonic acid gas or ammonia would blight or kill, not feed, their tender foliage. Some, who have not carefully guarded against this, have mixed rank London or other manures with that already in use, and the whole "mass has gone off like a cannon" to use the expression of an experienced gardener, who lost a most promising crop of Muscats through the indiscretion of mixing part of a truck of such manure with an exhausted mass of decomposing leaves and manure in a Vinery; but, with careful preparation and use and a bi-daily turning of this mass, there is little or no danger. The heat evolved is also strong and constant. Full half the amount of coal may be saved in the early forcing of Vineries by a judicious use of decomposing matter in association with other necessary warming. This is an important point, as the cost of coal is one of the most serious drawbacks to early forcing and to the more extensive production of tropical fruits and flowers. Neither is there anything new in this utilisation of a cheap and natural source of warmth. It has been almost universally employed in the culture of Pine-apples and other tropical plants, for the entire hot-bed, used as a means of bottom-heat, also becomes, and is, one of the most potent means of warming the atmosphere also. And if so useful and powerful in Pine culture, there seems no good reason why it should not be more generally used for Vines also. And, indeed, it is very generally used. Many of our very best Grape growers look upon the genial heat arising from decomposition as the most potent factor in their success, and seldom start an early house without their bed of leaves and manure. About

two parts of the former to one of the latter keep a steady heat for a long time. A week or ten days preparation should take place in the open air, during which the mass should be turned over, upside down, and inside out three or four times, at least. A bed or ridge 4 ft. or 5 ft. in thickness will generally prove sufficient. Where such materials are not available, tan is perhaps the next best substance to use. It gives out a good heat, but its vapours are less kindly, and its gases less feeding than those already indicated. Cocoa-nut fibre refuse, sawdust, &c., are less suitable, and can hardly be called feeding. Unless, in fact, leaves, manure, or tan can be had, it will hardly be worth while to employ other substances as sources of heat in the starting or forcing of Vines; but with these at command, the cheap and most efficient source of heat derived from decomposition should be employed in all cases where there is sufficient room or proper conveniences for their use.

D. T. FISHER.

TEMPERATURE OF VINE ROOTS.

THE unsatisfactory way in which the Vines described by "W. X. Y." (p. 188) have broken, with their roots in an outside border wholly unprotected, is just what might have been looked for, especially in such a winter as this, and is another evidence of the mistakes generally committed by following extreme courses. I have received several communications from different parts of the country relating to early started Vines with their roots outside. In one case a moderate amount of fermenting material was put on the border at the starting time, and some was added subsequently to keep up the warmth, but the shoots moved so slowly and unevenly that an examination of the border was thought to be the wisest course. The small roots near the surface were found to be rotten, and the cause was attributed to the saturated condition of the soil from the great quantity of snow that had fallen there, and which, as it melted, settled through the covering material. This conclusion is most likely to be correct, as the fermenting matter, I understand, was never above 70°; consequently, there was no excess of heat to injure them. In another instance the mulching of dry leaves and dry litter was put on as heretofore, early enough and in sufficient quantity to keep in the stored-up summer's heat, but with nothing on the top to throw off the wet. In this case the shoots are strong, but have come slower than usual. In other cases, where the dry covering material was put on, and means taken to ward off the wet, the condition is described as in every way satisfactory. This all points in one direction, the necessity for taking means to keep in the accumulated summer's sun-heat by putting on the covering sufficiently early, and the equal need for keeping out the winter rains and melted snow from the soil in which the roots of early forced Vines are placed. This is not a costly operation, nor difficult where the roots have not extended beyond the limits of the border.

Twenty-one years ago I had a quantity of shutters made of 3-in. boards, 9 in. wide, cut from ordinary American Spruce deal; these were nailed four together, edge to edge, to cross pieces of the same material, and on the joints were put strips 3 in. wide by 1 in. thick. The whole received two coats of boiling gas-tar on the upper side, and they were again dressed with the tar two years afterwards. Nothing has been done to them since; they have been exposed to the weather all the time, and I have now a number of them forming the roof of a shed, and they look as if they would last a good many years longer. They were made by the garden men, were cheap, and evidently have been durable. After the dry material was put on the borders, these shutters were laid on the top, with their bottoms resting on an ordinary spout made of boards like them, and which carried off the water that otherwise would have settled in the border, just at the point where the greatest quantity of feeding fibres were located.

When the roots of Vines have to any considerable amount got outside the prepared border, it is obvious that little can be done for them either in the way of protection, keeping in the earth heat, or supplying more to it; and few who have had much to do with Vines, are unaware that by far the greater quantity of such as have been established for any length of time, and that are not subjected to root-lifting, and thus their roots to a great extent kept within the prescribed space, have often very few feeding fibres, except such as are far out into the ground beyond. Nothing is more common than to hear roots spoken of which are supposed to be in the border, when, on examination, all that have direct influence in sustaining the heads of the Vines, are found to be quite outside the situation allotted to them; and in this way are as incapable of being influenced by the well-meant but useless attentions given to the prepared borders, as if they belonged to another set of plants.

T. BAINES.

PLATE CLXX.

A GROUP OF DAFFODILS.

Drawn by Mrs. ROBERT MILES.

Up the mountains the Greeks buried their dead, and there they lay o'ershadowed by a canopy of Asphodels, whose flowers twinkled on their branches like evening stars—a fit type, the Asphodel, of the Resurrection, with its dead blooms, and blossoms, and buds, as of days that were, and days that are, and days that are to come. And so these dreamers came to think that when a new life was come to the sleepers they would wake in Elysian fields, in meadows one mass of ever-blooming Asphodels. And whoever is responsible for our English name "Daffodil" thought that these saffron flowers were the Asphodels of the Greeks, and so called them "Fleur d'Asphodel," from which we get the corrupted name Daffodil. Let us keep to this beautiful derivation beyond all others, and learn humbly from it that our own churchyards might be as full of Daffodils as the Elysian fields were of Asphodels. We ought to plant the commoner kinds in such numbers that the village children might pick and pick, and yet could not pick them every one. Of those kinds to be planted by the thousand are the common Lent Lily (*Narcissus pseudo-Narcissus*) and its giant variety (*N. maximus*), with the large two-coloured Daffodil (*N. bicolor*), and the small form (*N. minor*), which is one of the first flowers of spring. The Poet's Daffodil (*N. poeticus*) and its double form can be obtained by the thousand from orchards near London for a mere trifle, and the Peerless and Scented Daffodils (*N. incomparabilis* and *N. odoratus*) will soon be very common. Of the Daffodils in the accompanying plate, the nearest on the left is the large form of the two-coloured Daffodil, known as Bicolor Horsfieldi; it is hardly represented as large as life. The Empress is a larger form still of *N. bicolor*, and the Emperor is the largest of all Daffodils. Next to Horsfieldi, at the top, come two portraits of a pale form of the Peerless Daffodil (*N. incomparabilis*); on the left, half-way down the page, is the Poet's Daffodil (*N. poeticus*), whose double form is as lovely as a Gardenia. Immediately next to that comes the rare Cyclamen-flowered Daffodil (*N. triandrus*), some forms of which have white crowns. That pale, self-coloured one in the middle is *N. cernuus*, a fine companion for *Anemone fulgens*. Lower still comes the rare white Hoop Petticoat (*N. Bulbocodium monophyllum*), which is certainly not easy to grow. I don't think this has been properly represented before. Observe the deep lobing on the fringe of the petticoat—a flower opening here, of the purest white, full of light, like frost on a window pane. If one person, by this picture and these notes, has been seized with a fancy for Daffodils, our labour will not have been in vain.

FRANK MILES.

Bingham.

Daffodil Culture.

There are but few species or varieties belonging to this family that are not perfectly hardy, or that will not succeed under ordinary circumstances in the open border. A few kinds, principally from Algiers, Spain, and the islands in the Mediterranean, consisting of *N. pachybulbos*, *viridiflorus*, *calathinus*, *Broussonetti*, and the various forms of *Corbularia*, and some others, flower mostly during the autumn and winter, and consequently are not adapted for out-door cultivation, except in very favourable situations. I have made several attempts to grow some of these out-of-doors, but have always failed. I have flowered them, it is true, but their blossoms and foliage get so much injured by the weather that the bulbs become emaciated, and in the second or third season disappear. Fortunately there are, as I have said, but few of this character; the great bulk are not only perfectly hardy, but will grow in almost any soil or situation, and increase in numbers rapidly. By means of hybridisation, too, it is possible to obtain varieties much superior to any yet in cultivation, and the process is so simple that any one may practise it with a fair chance of success. Most of the *Narcissi* prefer a good, rich, friable loam, annually enriched by a top dressing of manure. I believe in heavily manuring for all bulbs, Lilies especially, but care must be

used to keep the manure away from the bulbs while in a fresh state. For the small early flowering kinds, such as *N. rupicola*, *N. Bulbocodium intermedium*, and others of like character, I would recommend a sandy loam, and the bulbs to be planted in rather drier positions than the vigorous forms of *bicolor*, *Telamonius lobularis*, &c. All this family require replanting every three or four years, some even in two, but this depends a great deal upon the condition under which the bulbs are placed. The best criterion as to when they require replanting, is the production of small, weak foliage and a scanty proportion of flowers. When that occurs, one may make sure that

White Hoop-petticoat *Narcissus* (*N. Bulbocodium monophyllum*).

the bulbs have exhausted the soil, and that they have not sufficient room and strength to fully develop themselves.

Hale Farm Nursery, Tottenham.

A. PERRY.

***Myosotis dissitiflora* Injured by the Severity of the Winter.**—This usually beautiful spring garden plant is now in a deplorable condition. I have never seen it so much injured, and fear that it will make but a poor display, although it now shows evidence of breaking up afresh from the roots.—A. D.

ROSES.

PROTECTING AND FORCING.

PROTECTION FROM FROST.—Let us now proceed to describe the various ways in which Rose trees are protected from frost. The Brier in its natural state is not hurt by frost, but the grafted varieties are more or less tender. Rose trees, however, like other plants, are differently affected by frost, according to the circumstances in which they are placed. For instance, a shrub which would bear cold amounting to 15° or 20° below the freezing point, provided the thermometer fell gradually and in dry weather, would perish if such a degree of cold were to set in suddenly before the sap had begun to flow, or after its shoots had been swollen by rain or a thaw. Again, if the same Rose tree were planted in light, sandy, dry soil it would not be injured by cold some 20° below the freezing point, while in a strong, clayey soil, capable of retaining a good deal of moisture, it would perish at a much higher temperature. In order, therefore to be prepared for danger, we must inquire into the different kinds of Roses which we are cultivating, the nature of the soil, the aspect of the beds, and the general state of the climate of the locality.

SHELTERS FOR DWARF ROSES BUDDED AND ON THEIR OWN ROOTS.—Dwarf Roses are generally planted in beds or in borders. During the first fortnight in October we earth up each bush as far as the first branches. The earth used for this purpose should be fresh, and rather light than heavy. The watery shoots which project beyond the prescribed limits are cut back. The interstices between the branches are then filled in with leaves, so as to form a heap round each Rose of from 14 in. to 16 in. thick. This mound of leaves and soil is kept in its place by covering it over with branches of some green shrub, such as Broom. If necessary, a layer of straw, forming a kind of slanting roof, may be constructed over the leaves so as to throw off the wet.

SHELTERS FOR STANDARD AND HALF STANDARD ROSE TREES.—When the stem of the Rose tree is sufficiently flexible to allow us to bend down the head to the ground, we bring it half under and half above the level of the soil, covering it over with a heap of leaves as above described. The stem is surrounded with a packing of dry Moss or Hay, kept in its place by a straw covering, and, finally, the base of the tree is earthed up and surrounded with a mass of dry leaves. The whole is kept firm by means of a training stick, which is inserted in the ground at the highest part of the curve made by the bent stem, the two being firmly tied together in the usual way. When the stems cannot be bent without danger of breaking them, we must begin by cutting the principal branches of them even with each other. Their ends are now brought together and tied, and the empty spaces between them filled up with dry Moss, the whole being kept in its proper position by a second tying. The head is now surrounded with Moss, and the lower part of the stem is earthed up and covered with Rye straw, beginning from the bottom. The ears of the straw, if it has any, should be upwards, and the lower part should spread like a thatch over the surface of the leaves forming the mound. The upper portions, in the same way, should spread out and project beyond the head of the tree, and be brought together above the head, and firmly tied together in the form of a double cone. The apex of the cone should be covered with a flower pot, the hole of which has been closed by a cork, the whole being firmly attached to a wooden support driven into the ground. It must be understood that if a single length of straw is not sufficient, we must use two layers instead of one, taking care to begin at the bottom. As soon as all danger of frost is over the coverings are taken off; but it is as well not to be in too great a hurry over this operation, because, on account of the trees having been kept so well covered, they will have put forth numerous delicate shoots, which are not accustomed either to the least cold or to the hot rays of the sun, so that in any case we should take away the coverings when the sun is not shining. All the precautions which we have described above are not sufficient to guard against the effects of frost on dormant shield-buds which have been grafted at the latter end

of the season; we must, therefore, protect them further by surrounding them with a dry Maize leaf, with oiled paper, or with grafting wax.

ROSE FORCING.—The varieties preferred for forcing are Rosier du Roi, La Reine, Jules Margottin, Madame Boll, Souvenir de la Reine d'Angleterre, Louise Peyronny, Blanche Laiffé, Bengal Cramoise Supérieur, Tea-scented Roses, such as Souvenir de Malmaison, Madame Falcot, Mârchal Niel, Safrano, Madame Lacharme, Mrs. Bosanquet and Lamarque. These varieties are grafted on low stocks at about 4 in. from the ground, and form dwarf Rose trees fit for pot culture. Before potting, the roots must be trimmed and the suckers cut off; they are then planted in 6-in pots in a mixture of equal parts of fresh mould and well rotted night soil, which has been passed through a fine sieve. The potting generally takes place in November, and the potted Roses are buried in the borders of the garden, placing the pots on their sides, and protecting them from the cold with an abundant layer of litter. In the month of April these Roses are planted out in borders, so that each border may contain five rows. They are then pruned, the strongest branches being chosen and cut down to within 8 in. of their base, all weak shoots, producing nothing but leaves, being got rid of. The surface of the bed is now covered with a layer of manure, which will do much to keep the roots of the Rose trees moist. The trees, however, must be copiously watered during summer. In the November following these operations they are taken into the forcing house. The tips only of the branches must be pinched off, for in this case quantity is of more importance than quality. The pots are placed either in the frames of the forcing house, or on a layer of stable manure about 8 in. thick, made up on the surface of the tan in the frames without plunging the pots, which must be kept at a certain distance from each other, otherwise the plants are apt to become weak and "leggy." To keep the soil in the pots constantly moist, their surface is covered with a good layer of stable litter, and watering is kept up during the whole time of forcing. One very essential point is to keep in the forcing-house several barrels filled with water, which must be always kept at the same temperature as the house itself; that is to say, at from 60° to 65° . According as we want to force the growth of our Roses, and obtain a supply of blooms for a certain predetermined date, we must allow a period of forty or fifty days for the plants to flower fully. If we notice any aphides on the tops of the shoots, we must lose no time in giving the plants several copious fumigations with tobacco during the night, until these troublesome pests be eradicated. If these Rose trees are grown for commercial purposes, they are sent to market as they come to perfection, and are replaced by others. This kind of succession of forced Roses lasts until the month of April, the remaining subjects being planted out in the open air, after having been unpotted. M. Laurent, of the Rue de Louvre, at Paris, is at the head of the forced flower trade. With him winter does not exist, and from November to May he supplies the market with a constant succession of Roses and Lilacs, these flowers being sought after more than any others, for bouquets and head-dresses for dinners and balls.

The method of forcing Roses for cut blooms, differs from that adopted when the trees are sent to market in pots. The trees are planted in the soil of the frames of the forcing-house itself. Thanks to the perfection to which the art of heating by hot water has been brought, we can regulate the temperature at will, at the same time leaving the glasses of the frames quite uncovered, so that the colour of the blooms is in no way interfered with. Failure takes place in only such severe winters as that of 1871-2. Rose trees forced in this way have the woody portions of their branches only half matured. As soon as May arrives, the lights of the forcing house and the frames must be opened, in order to give them the full benefit of the summer. It is just at this period that the Rose trees should undergo a fresh pruning, which consists in cutting out all weak shoots, which only tend to entanglement, and shortening the bloom-bearing branches to a length of about six inches. Watering must of course be kept up, and the ground weeded and hoed as often as may be necessary. There is but little trade done in Rose-buds during the summer and autumn, ex-

cept at the feast of St. Mary, September 8th, when they will fetch as much as four francs a dozen, every lady bearing the name of "Mary" being presented with rose-buds by all her friends on that day.

FORCING ROSES IN FRAMES.—It is not at all necessary to have a forcing-house in order to force Roses. The following is the method adopted by the Paris florists, in order to procure a supply of Roses early in the spring. Rose trees are potted a year previously, and kept in the borders of the garden. Towards the beginning of November the pots are taken out of the beds, and laid by the heels with the plants in a slanting direction, so as to avoid the growth of the wood and hasten the fall of the leaves. About the middle of December, or a little later or a little earlier, according to the weather, the pots are placed in their proper position. For this purpose a bed is dug, and the necessary number of frames placed upon it. In each frame we plunge eight pots, reserving a space about 10 in. broad along the sides of the frames, and the whole is covered in with the lights. Frames for Roses ought to be 2 ft. 2 in. high in front, and 2 ft. 8 in. at the back. The Rose trees, which should be kept fairly watered, remain in the frames until the eyes are swollen. The shoots above the eyes are cut down, and all useless shoots are got rid of. The pruning over, the frames are surrounded with a wall of stable manure, running all round the frame and overtopping it by about 6 in. or 7 in. The wall of the manure should be 2 ft. wide at the base, and 1 ft. 4 in. wide at the top; in about ten days the manure will be in full fermentation. We must now thoroughly uncover the frames in order to get rid of the ammoniacal fumes, which are fatal to Rose trees, as well as of the damp, which would cause the plants to wither if fresh air did not dry the leaves and buds thoroughly. The frames must therefore be propped open every day when the weather permits, and covered with straw mats at night. It must be understood that the mats are never taken off except the sun be shining. The growth of the plants must be looked after, insects must be rigorously destroyed and the green fly put to flight with copious fumigations of tobacco, given in the evening. The protecting walls of manure should be turned once every fortnight. Rose trees treated in this way, generally bloom about forty days after they are placed in the frame. Counting forty days as the period necessary to bring a Rose tree to perfection, we can so adapt our supply of pots to the frames, that we can have a succession of blooms from the beginning of February to the middle of May, when the first Roses grown in the open air begin to make their appearance. J. LACHAUME.

THE KITCHEN GARDEN.

NOTES ON SEED SOWING.

Sow only seeds of good quality, both as regards germinating power and pure stocks. When a failure occurs badly-prepared land or careless sowing is often the main cause. A favourable seed time can generally be had by watching and waiting, and promptly taking advantage of it when it arrives; it is better to wait a few days than to sow when the ground is in an unfit condition to receive the seed. But with land difficult to work in a backward season a crop may often be successfully got in with the aid of a few light boards laid across the bed; this, in some cases, may perhaps involve a little more labour, but it insures success. The same means may be usefully employed in transplanting in wet seasons, as nothing makes land that is naturally adhesive so unfit for plants as treading on it when its surface is wet. All seeds are best sown in drills, at varying distances, according to each particular kind, but, in all cases, room should be allowed to use the hoe freely. Both thick and very thin sowing are, in certain cases, evils to be avoided, but the character of the land should be considered in deciding what quantity of seed to sow. On light, warm land, where every seed will grow, fewer seeds should be sown than on damp, heavy land, and where, perhaps, in a cold, unfavourable season, slugs and other insect enemies may be troublesome. Besides, no matter how good the seeds may be, some will produce better and stronger plants than others, and there should

always be sufficient plants on the ground to allow of a choice being made, so that the crop, when finally thinned, may consist of selected plants only. Those who have had much to do with young plants will understand the importance of this, although, it may be, the work of thinning is often delegated to workmen who ignore or overlook its force.

The depth at which seeds should be buried should bear some proportion to the size of the seed; but the character of the soil in which they are laid is even of more importance. In warm, dry soils seeds may be safely and advantageously placed deeper than where the soil is of a heavier nature. Drills for what are termed small seeds need not in any case be more than $\frac{1}{2}$ in. deep, and less will suffice on heavy soils. In the latter case, unless the soil be in a mellow condition, cover with a prepared compost, of which burnt earth, or decayed vegetable matter from the waste heap, forms the chief part. When this plan is adopted, no matter what the soil or the season, the seeds will germinate regularly and well. Larger seeds, such as Peas and Beans, may be covered 2 in. for early crops, while later sowings may be put in a little deeper. The same remark applies to later sowings of small seeds, such as those of Turnips, as it often happens in dry weather, by burying them just a little deeper, the seeds can be laid in moist soil, and will, in consequence, germinate more speedily, and when seeds lie long in the land the crop cannot be so even or regular. In certain cases the germination of seeds may be hastened by mixing them with some damp substance, such as sand, or by soaking them in water for twenty-four hours or so before sowing, but the most natural way is usually the best, and artificial plans should only be adopted where, from some unavoidable cause, the sowing of the crop has been delayed.

All seeds should be sown on moderately firm land; for some plants, such as Onions, this is indispensable, and it is especially necessary if the land be of such a nature as to not readily consolidate or settle down, and there is a vast difference in different gardens in this respect. Treading is the means commonly adopted to secure solidity, but where land is very light, the iron roller may be drawn over it twice in contrary directions. If the surface be not sufficiently dry to bear the roller at the time of sowing, or even the feet, delay sowing till the surface is in a suitable condition. This need not, however, interfere with the sowing of the seeds, as the final treading or rolling may be given a week or ten days after the seeds have been sown, and it will be better to do it then than not at all.

There is nothing better than lime dustings to preserve young plants from the attacks of slugs, and very early in the morning or late in the evening, is the best time to apply them. Stirring the surface among the young crops the moment they appear, freely and often, will also help to keep the slugs in check, as they cannot travel well over a rough, uneven surface, and the stirring will also encourage and stimulate the young plants to grow up out of their reach. Scattering dry ashes over any crop to which slugs are partial, is likewise a good preventive, as their soft, slimy bodies can't get over the sharp, jagged edges of the small particles of cinder with which sifted ashes abound.

Where mice or birds are numerous and troublesome, the seeds should be thinly coated with red lead just previous to sowing, in order to make them distasteful. This is easily done; first, damp the quantity of seeds to be sown with water or oil; then scatter a little dry lead over them, and stir and mix altogether. It must not be forgotten by persons unaccustomed to the use of such substances that red lead is poisonous. Paraffin oil may also be used for soaking seeds in to preserve them from vermin, but as commonly sold in the shops it varies greatly in strength, and should be used first experimentally till its effect has been ascertained. E. HODDA.

SPADE HOES.

A HEAVY iron hoe appears to be the universal implement employed for land culture by all half-civilised races, and perhaps under all circumstances no other would be so generally useful. In the Economic Museum at the Crystal Palace, Sydenham, there are one or two examples of "fasses" or spade hoes used in Egypt,

and Livingstone, in his volume of "Missionary Travels" (London: John Murray, 1857) illustrates two similar forms which he saw used by the African natives of Batoka and Angola. Both consist, as will be seen, of a heavy iron blade set in a stout wooden shaft. The Angolan form is peculiar, however, in having two shafts which diverge from the blade at an angle of about 22°, and on being struck into the soil the two plough-like handles give the operator a greater leverage power than one would naturally do. The other implement illustrated may be taken as the type of that adopted by the Chinese emigrants in the Straits Settlements and Eastern Archipelago generally; indeed, wherever a Chinaman sets his foot in a new locality for

Batoka Spade Hoe.

cultural purposes, a chopper and a blade or two of his national "chunkal" or spade-hoe are sure to form a part of his extremely small belongings. He sets to work by cutting the brush wood and small timber on his future clearing, and piling this at the base of the large trees, he fires the whole until only a few great black stumps, and here and there a gaunt, leafless Dorian or Dryobalanops remains of the old forest. Now, the "chunkal" is used to stir the virgin soil by chopping it up, a much quicker process than digging; indeed, a spade would have no chance in a competition where, as in this case, the soil is full of roots. If desirable, the soil can be thus chopped up to a depth of 12 in. or 14 in., the only drawback being that the operator stands on the freshly cultivated land. Armed with a chopper and one of these spade-hoes, a solitary Chinaman will not unfrequently build a miserable little Palm-leaf hut on a well watered bit of forest near a river, and in a month

Angolan Spade Hoe.

or two he will have cleared several acres, to which, when planted with Gambier or Pepper, he looks for a fair return. Here, alone in the tiger-infested forest, or at the best with a companion or two equally poor as himself, he subsists on a little boiled Rice, until his crops of Sweet Potatoes, Bananas, Sugar cane, Egg fruit, Maize, and Yams are fit for use; for one of his first cares has been to clear the bit of land around his hut, on which to plant the few roots and seeds which he has brought with him, most probably the gift of one of his richer countrymen, perchance of the trader of whom he bought the bag of rice, which with a little freshly caught fish from the river, are the only "stores" which stand between him and

starvation, until his garden produce is available. I have often come across these clearings right in the heart of the forest, miles away from any other human habitation, and have been as much astonished at the amount of labour performed with such a simple tool, as the thrifty labourer himself was to see me. Practically, I found one of these heavy sharp-edged hoes invaluable for taking up shrubs and plants in the forest—a much more difficult operation than one would imagine—since the earth an inch or two below the surface is often thickly interlaced with strong roots. In English gardens such an implement—which any blacksmith could soon make—would be of great practical use in clearing shrubberies and plantations, as well as for earthing up operations of all kinds. It must be well steeled along the cutting edge, and should be made strong and heavy enough to sever roots as thick as the wrist at a blow. It will then be found a really useful and practicable implement; a combination of the awkward old grub-axe with the hoe and spade, and invaluable for cultivating land near hedges and trees where roots are plentiful, and where the use

"Chunkal" or Chinese Spade Hoe.

of the common spade, to say the least, is extremely inconvenient. I. O. U.

ADVANTAGES OF PLANTING POTATOES EARLY.

LAST year was an exceptionally bad year for Potatoes, and it is not surprising to find growers condemning good kinds, such as Climax, which may be new to them. I never had a more striking example of the importance of early planting on the size and quality of the crop than last year. In the first place I will speak of a good breadth of Lapstones. This, with me, is usually the best of all Potatoes, and I have grown it more than twenty seasons. Early last year I trenched a piece of ground three spits deep, throwing it up into ridges 2½ ft. wide. I manured it with the contents of a rubbish heap, consisting chiefly of rotten leaves and lawn sweepings. In fine, dry weather, about the middle of March, drills were drawn between the ridges. The sets were carefully planted, and the ridges were forked over, making the ground level. About a fortnight afterwards the remaining portion was trenched, treated, and planted in the same way. Those planted first were up a few days before the rest, but in a short time no difference could be seen, and when in flower no trace of any rows existed, as far as general appearance went, but the disease set in earlier than usual, and with unwonted severity, and on the whole, in a fortnight, not a green leaf was left. When dug, in the middle of August, those first planted were twice as large as the tubers of the second lot, but the quality in both cases was close and bad.

With reference to other sorts grown under plough culture, let us advert to an adjoining field. This, consisting of two acres, was twice ploughed, dragged, harrowed and rolled, and got to a fine tilth, and the Potatoes (two sorts, Fortyfolds and Regents) were ploughed in from 6 in. to 7 in. deep, and 3 ft. from row to row, the plough turning a 1½ in. furrow each time. The planting of the field was finished in two days (the 18th and 19th of March); the weather being fine the crops were

put in under the best of circumstances. A little Guano was sown in the furrow with the seed, and nothing more was done until the young plants began to show themselves above the surface, when the ground was lightly harrowed in order to kill all small weeds. As the Potatoes grew they were twice horse-hoed, the second hoeing covering Hussey's Grey Stone Turnip seed, sown by hand from a tin powder canister with a small hole in it. Nothing more was done until the tubers were dug in the middle of August, when the Fortifolds (having succumbed to the disease soon after the Lapstones) turned out to be a small sample but of good quality; the Regents, the haulm of which was only partially affected, proved to be a fine crop and excellent in quality, whereas Regents, grown by cottagers to whom I gave some seed, planted a month later, proved small and close, although well cultivated; a decided proof, according to my opinion, of the advantage of early planting. When dug the crop is taken to cool dark sheds and picked over. About two or three weeks afterwards, the seed and eating sorts were stowed away in their respective places, and they have not been picked over since, as this season, owing to the cold weather, they have not begun to grow yet.

On the headland of the field on the south side, after the Potatoes are planted, I sow Savoy, Drumhead Cabbage, and Thousand-headed Kale. These, when transplanted, make up for any deficiency that may occur in the Turnip crop sown amongst the Potatoes. Some of the Turnips measured 22 in. in circumference. The culture of this field for both crops is even less than that which an adjoining field receives for a Turnip crop alone under a good tenant farmer, and we get our crop of Potatoes with no more labour than that of dropping in the seed and digging the crop. For many years I have tried most of the new sorts sent out, and some years ago I exhibited over fifty kinds at South Kensington, but now for stock I rely on the above three old sorts. The field referred to is now well dressed with rotten leaves, and it will be ploughed up deeply as soon as fine weather sets in. The soil here being naturally well drained, I plant deeply and never earth up a Potato. Earthing up buries the first leaves, and thereby makes the Potatoes ten days or a fortnight later than they otherwise would be, which is of some importance when the disease shortens the season by setting in so early as it did last year. I ought to add that in my Potato culture not a single cartload of ordinary manure was used in either year during which I have grown Potatoes in the above manner. JOHN GARLAND.

Killerton, Exeter.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Winter Lettices.—During this long winter I have daily cut good Lettices of the Black-seeded Bath Cos variety, grown out of doors. The seed of it was sown in the first week in July, its produce was planted in good land, and when full grown covered over with 6 in. of light Bracken. This not only prevents the frost from injuring the Lettices but blanches their hearts. On St. Valentine's day I lifted several barrow-loads, and laid them in for use, the ground being wanted for spring cropping. —R. GILBERT, *Bughley*.

Magnum Bonum Potato.—It is most probable that the soil in which "B. H. J. S." (p. 190) has grown his *Magnum Bonum* Potato is far too rich. This variety, to be good for table, should be grown in soil that is comparatively poor and moderately dry. If *Magnum Bonum* comes unfit to eat in such soil, there are fifty other sorts considered good that would, if grown in the same soil, be in the same condition. The anxiety to secure a large crop induces planting to be done in a rich, fertile soil. This may suit the more delicate or less robust early or garden kinds, but in the case of large-growing sorts it is a mistake. Except where this is the case, I have not only heard no complaints of the quality of *Magnum Bonum*, but have heard it generally highly spoken of. I raised a splendid crop of moderate-sized tubers of this kind from land that had not been manured for three years. —A. D.

Potatoes and Frost.—I trust no one will be disposed to take "Cambrian's" remarks as to the slight effects of frost upon Potatoes literally, and next winter be careless in protecting their stores. The more completely the frost is excluded the better, as not only does a slight attack affect the eating quality of the tubers, but it too often kills the bud germs, and thus induces blindness in the seed tubers. I observe that both "Cambrian" and Mr. Baines falls into the error of quoting Myatt's, Veitch's, Lee's, Rivers', and Gloucestershire

Ashleaf Kidneys as distinct kinds. Nothing can be more delusive. The exhaustive trial of Potatoes undertaken at Chiswick a few years ago, and which fully settled the question of distinctness or otherwise in relation to numerous kinds, showed that all these so-called sorts are one and the same. Where, again, is the difference between Dalmahoy and York Regent, except in the imagination? As to recommending the Regent, I would strongly recommend its not being planted. A sort that it is almost certain will show a crop more than half diseased is worse than useless. —A. D.

GARDENING FOR THE WEEK.

Conservatory.

Camellias in pots as they go out of bloom in conservatories should be removed into the houses in which their growth is to be made, and their places should be supplied by plants that flower later, so as to keep up a succession. Even in places where considerable numbers of Camellias are cultivated, it often happens that none of the varieties that possess a natural disposition to bloom late are grown, which is not only a mistake, so far as regards the flowers for cut purposes, but also from a decorative point of view, as, when the Camellia bloom is over, especially in large conservatories, it is a difficult matter to find flowering plants of size sufficient to take their place for general effect. Azaleas, if brought into flower as recommended, will now be very useful for these structures, and so will also Genistas, Acacias, Epacrises, *Habrothamnus* (grown as standards), Lilacs, Deutzias, *Prunuses*, *Gaultherias*, *Rhododendrons*, *Ghent Azaleas*, and similar forced shrubs. By the assistance of these, combined with smaller growing plants, such as *Cinerarias*, *Cyclamens*, early-flowering *Pelargoniums*, and the late batch of *Primulas*, *Hyacinths*, *Tulips*, *Lily of the Valley*, and *Narcissi*, a display may now be forthcoming, which it is not easy to equal, either for quantity or diversity, at any other time of the year.

Insects.—Through the little extra warmth required in conservatories, coupled with the fact that many of the plants have been brought on into bloom in a higher temperature, aphides are certain to make their appearance on some, and if continual watchfulness be not maintained, so as to destroy them, they soon spread to an extent that entails very much more labour later in the season. At no time is it so necessary to take means for keeping these pests in check as conservatories are necessarily moved backwards and forwards to other at the present, when the various subjects that have to do duty in a houses. If these insects be not killed on their first appearance, the occupants of almost every house in the establishment get infested with them. There are several objections to fumigating conservatories, especially when attached to the dwelling, where the odour from Tobacco, or of the various preparations now made from it for using in like manner, is highly disagreeable for some days after. To avoid this, any plants found to be affected should be taken out and fumigated elsewhere. For this purpose I have found it well to employ a small, tent-like contrivance, consisting of a light, wooden framework that could be set up in a potting shed, or any outbuilding sufficient to hold a considerable number of plants, by covering the whole up closely with any available material, such as canvas, Peach blinds, or mats, and if a good oil sheet happens to be at hand, putting it over all, the fumes can be kept in until the insects are killed. If two or three applications be given to effect their destruction, without its at any time being so strong as to injure the plants, it will be much better and more economical than fumigating the conservatory, or even a large house, when only a limited number of plants require to be treated in this way.

Shading.—The sun now begins to be powerful, and there is a disposition, in flowers as the season advances, not to last so long. This particularly becomes apparent if no shading is employed; but fixed shading is at all times injurious in its consequences, and should never be used if it can be done without, where there is a desire to grow the plants well. At no season are its effects worse than in the early spring, when the young, tender shoots and leaves require all the light they can possibly get, and where, although there may be a necessity for shielding the flowers from the direct rays of the sun for a few hours in the day, during the very much longer period when nothing is needed, the shade does much mischief. On conservatories with plain roofs there is no difficulty in the matter, by merely using blinds with the ordinary rollers; but on those that are more elaborate in their construction they are generally unworkable, necessitating resort being had to fixed material, but this, when so employed, should always be very thin and light-coloured. The coloured shading of every kind is an unmitigated evil, for the simple reason that it darkens the plants proportionately as it is removed in colour from white.

Greenhouse.

Potting Hard-wooded Plants.—Plants of this description are now potted much earlier in the season than at one time was considered the best; then the operation was deferred till towards the end of April or May, when more active growth had commenced, but this naturally had the effect of subjecting them to greater danger of death or injury by the disturbance of their roots when the drying influences of sun and air were more powerful in their action on the wood and leaves, and, in addition, the state of the weather necessitated the admission of more air to keep down the temperature in place of the confined, close state of the atmosphere it is essential to provide for a few weeks after potting, and which can be managed so much better whilst the weather is comparatively cool. Sufficient soil should at once be prepared, both peat and loam, proportionate to the number of plants that require one or other, in all cases breaking it by hand instead of sifting, except for plants that have only just advanced beyond the cutting stage, and I may here urge that, despite what may appear to be extravagant practice in rejecting much more of the solid earthy portion of the soil, and confining the use comparatively more to the fibrous matter, this will in the end prove the truest economy, as not only will the plants grow away in such material a deal faster than in the soil, compacter soil, but those of an enduring character and expected to keep on for a number of years will be far less liable to get out of condition and die prematurely. At the same time it may be necessary to point out that when soil of the description advised is used it requires more care in compressing it closely in the pots. All the pots requisite should be in readiness—new ones so far as wanted, and old ones cleansed—with crocks broken to the sizes needed, and also washed clean if they have been before used for a like purpose, with the necessary labels to replace all that have become illegible, so that the work can go on and be completed in a systematic kind of way.

Where there is a very large number of hard-wooded plants, it is usual to commence with the smallest first; there is one disadvantage attending this, that it necessitates a considerably larger quantity of pots on hand—stock always liable to breakage—whereas, if the large specimens are potted first, gradually coming down to the smaller, the pots that are thus set at liberty can be used for the latter, but this, of course, must be subject to the condition and immediate want of shifting of the different plants to be operated upon. On those whose experience has been more confined to plants of a soft-wooded, quick-growing character, it may be necessary to impress that, to prevent, as far as possible, the injury liable to be inflicted on hard-wooded subjects in removal, through the breakage of their roots, which are so much longer in repairing any harm they sustain than are plants of a more rapid-growing, hardy description, it is requisite to take every precaution not to disturb them more than is unavoidable. The system once thought needful of loosening the roots from the old ball is most disastrous in its consequences; incalculable numbers of tender-rooted, hard-wooded plants have been destroyed by it. Even when absolute death does not ensue, it frequently takes months before there are a sufficient quantity of healthy feeding fibres to supply the place of those mutilated. It is also of importance with this class of plants to see that the soil which the roots are already in is well moistened before potting, so as to allow all the time possible to elapse before water is given after they have been placed in new material, for the reason that when due care has been taken to avoid any injury to them, a good number will be broken in the necessary removal of the old drainage from the bottom of the ball, and if water has to be given before these have had time to heal up, the wet condition of the new soil, laying in absolute contact with them at the bottom of the pots, often causes them to rot back so far as to destroy the plants. This, unquestionably, is the direct cause of death after potting, although it may often not take place for many weeks, or even some months later. After potting, it is essential that the plants should be kept for three or four weeks closer than usual, admitting little if any side air, and keeping the atmosphere moist.

If the plants are standing on shelves or stages the ground underneath should be moistened, the evaporation from which will be sufficient for the purpose, as hard-wooded plants generally are better not syringed, except with a view to remove insects, or for a time after being out back. If the weather comes very bright, it will cause the temperature to rise considerably, but as this, so early in the season, will rarely be more than for a few hours in the middle of the day, it will do no harm if the roof ventilators be open. Even in the case of plants that are not to be potted, and that usually receive a maximum of air, such as *Heaths*, it must be given very sparingly at the sides or not at all during this and the next month, when the wind happens to be of the dry cutting character proverbial at this season, for, if admitted in a current upon even the old foliage, it is often very destructive in its effects. In span-roofed houses where means

exist, as they ought to do, of giving air at both sides, a little can always be admitted at that opposite to the direction from which the wind happens to come.

Tender Annuals for Pot Culture.—If a little seed be now sown of *Balsams*, *Globe Amaranths*, *Celosia pyramidalis*, and *Cockscombs* they will come in early for conservatory and greenhouse decoration. It is not well to sow the seeds in more heat than is necessary for their healthy germination, and in raising the young plants at this season, it is essential that, from the first of their appearance, they be placed as near the glass as possible, for, if they become in any way drawn up weak and spindly, no after attention can ever repair the injury; for a like reason they should always be potted singly as soon as they are large enough to handle.

Striking Zonal Pelargoniums.—These plants, as is well known, will strike at any time of the year, but the varieties intended for winter flowering I have always found to do much the best from cuttings struck the autumn previous or early in spring, times which give them a chance for getting the wood hard and solidified; without this condition, when subjected to the warmth requisite for the free development of flower through the dull season, they almost invariably are inclined to run to leaf rather than the formation of bloom. Cuttings taken off now, struck in warmth, grown on without check, and thoroughly hardened up during the latter end of summer, if properly managed afterwards, will well answer the purpose required.

Fancy Pelargoniums.—The disposition to cultivate plants that are more easily grown, has caused these to fall into comparative neglect. The present is much the best season to strike them, secure in the purpose the freest-growing shoots. They will root now much more certainly and quickly, and grow better afterwards than those put in when the old plants are cut back after flowering.

Fuchsias for the general display should now be encouraged to make all the growth possible, as, if they do not attain sufficient size early in the season, their natural free-flowering disposition brings them into a blooming state, rather than to shoot extension, when the weather gets hotter. Stop the shoots as requisite, to fully furnish the plants. Syringe them freely on the afternoons of fine days to keep down insects.—T. BAINES.

Flower Garden.

Auriculas.—A pleasant change has come over our specimen plants. A few weeks ago they were almost dormant, now the young leaves are expanded, and trusses are emerging from the centre of the crowns, showing by the development of the pips that the leaf covering is very favourable to their growth, as most of them are as far advanced as the side trusses that could be seen in November. See that the greatest care is taken to protect the young growths from cutting winds; also that the frames are covered with mats at night. We have a number of pots full of seedlings, as it was perceived that the seeds were vegetating as the frost set in about Christmas, the pots were taken out of the frames and placed in a greenhouse. The young plants have mostly formed a third leaf, and they must now be pricked off, say about twenty-five plants in a 4-in. pot. The pots are filled up with fibrous loam, leaf-mould, and a little rotten manure, merely using about $\frac{1}{2}$ in. of finely-sifted soil on the surface in which to plant the young seedlings; after potting, place the pots in a cold frame.

Carnations and Picotees.—We have now finished potting these, and have, as far as possible placed the plants under the shelter of glass lights; the object in doing this is to shelter them from high winds and heavy rains. Those who have not the convenience of lights had better improvise some sort of shelter. Mr. Dowell's garden at Clapham is exposed to the wind in all directions, and he has erected a framework which he has covered with hexagon garden netting. This would not answer quite so well as glass frames, but, on the other hand, no attention is required. He informs me that heavy rain drops are broken by the netting, and fall on the plants in the form of spray. The netting is also a sufficient shelter from high winds. No water should be applied to the plants for at least a week after potting. It is very desirable that each class and section be kept separate, and the varieties should also be arranged alphabetically so that any particular kind may be readily found. Begin potting the scarlet *Bizarres*, following on with crimson *Bizarres*, then pink and purple *Bizarres*; next come the flaked purple, scarlet, and rose in their order. Take of *Picotees* the red-edged first, following with purple and rose-edged, and lastly all the fancy varieties, comprising self *Carnations* and yellow-ground *Picotees*.

Hollyhocks.—The plants propagated in spring will not be quite ready to plant out until the first week in April, but old plants potted up in the autumn and cuttings struck at that time may now be

planted out on the first favourable opportunity. The work can be done even if the border be not in good condition, if there is a reserve of dry loam to place round the roots. I always do this with fine sorts; about two or three spadefuls of soil are taken out, and as much of the prepared soil put in its place; a compost of two parts dry loam to one of rotten manure from spent Mushroom beds answers well. See that the soil in the pots is quite moist before putting the plants out, this is better than watering after planting them.

Pansies in Pots.—For a cottager or amateur who cannot afford the luxury of a greenhouse, there are no plants better adapted for producing choice early flowers than these, or that can be propagated either from seeds or cuttings with so little trouble. Of course seedlings that had not flowered would not be grown in pots, which should contain only the choicest varieties. See that air is freely admitted to the frames in order to prevent the growths from being drawn up weakly. Only shut up close on frosty nights. Give manure watering at every alternate watering, as soon as the soil in the pots is well filled with roots. If the frame faces the south, it will be necessary to shade it, in order to preserve the flowers, during a few hours in the middle of the day.

Primula cortusoides and other kinds grown under glass are now making rapid growth. The pretty little *P. nivalis* should be grown in quantity; its delicate pure white flowers are very sweet, and are freely produced. *P. japonica* may be grown for the sake of variety, but it cannot be said to be either a king or queen amongst Primulas. The finest single and double forms of the common Primrose are easily grown; what they all want at this season is no lack of water at the roots, attention to cleanliness, and free ventilation. Insect pests are very annoying, and must be destroyed.

Tulips.—These are now mostly through the ground, and, to all appearance, are making a very healthy growth. One does not know what a day may bring forth, but with the 1st of March came a change for the better. The plants should, however, be protected from severe frost should it again occur, and that can be done as recommended in previous numbers. Hexagon netting, as used by Mr. Dodwell for his Carnations, I would prefer to any thicker covering.—J. DOUGLAS.

Hardy Fruit.

At length the long desired change in the weather has taken place, and with it comes a formidable array of arrears of work, which will require the most persistent energy to overtake. First and foremost should be the planting of any fruit trees that has yet to be done, after which, complete the pruning and nailing of all wall fruits, especially those that are on southern and western aspects; the trees on the northern and eastern walls are not so forward, and can, therefore, be left to bring up the rear. Fortunately, the protracted cold has had one good effect, and that is, that even if vegetation now should make the most rapid progress, all kinds of fruit will be later in flower than is usually the case, and, consequently, there is greater ground for hope that they may escape spring frosts, which are oftentimes so disastrous. A finer prospect of an abundant fruit season could not possibly be than there is in this district (North Hants) this season, and happily the birds have, by the hard winter, been thinned to something like a reasonable limit; therefore, there is little danger to apprehend from that quarter; still vigilance will be requisite to ward off any attacks which they may yet make, and also to have in readiness all protecting materials, to be applied as soon as the blossoms begin to burst. A few mild days will start all trees into active growth, and grafting of new or improved varieties of fruit on inferior kinds, can now be done. If the stocks were headed down a couple of months ago, all the better, though this need not be an obstacle, as no real harm will be done by cutting them down now. Clef or wedge grafting is that which we practise and recommend as being at once simple, expeditiously done, and effective. Work the clay well over the grafts in order to exclude both air and rain, and keep a reserve of clay to renew any damage that may be caused by frost loosening it from the stocks. Cuttings of Gooseberries and Currants can be made on wet days, and be planted now at any time. Single-stemmed bushes should always be preferred; therefore select the young growths of last year, which should be at least 9 in. long, twelve or fifteen not being too much. Pick out all the eyes or buds except two or three at top, and plant firmly in rows 18 in. apart and 6 in. apart in the row. They will root in a few weeks, and as growth proceeds pick out any buds that may appear near the surface of the soil or through it, the object being to form a tree that shall have a single stem, and be free from suckers. Transplant any cuttings that were put in last season, giving them about double the space which they have had as cuttings, and next year they will be sufficiently large to form permanent plantations. Established plantations of Gooseberries and Currants should be lightly "pointed" over and a liberal mulching of stable manure be afterwards given

them; lacking this, give them a dressing of lime, soot, or wood ashes, or the three mixed together, in which case the mixture should be applied when the trees are damp, and if thrown over them as well as on the ground, some of it will adhere, and not only kill Moss and Lichen, but keep off mischievous birds. Some varieties of Strawberries have suffered severely during the winter, and any not mulched prior to the frost setting in, are sure to be permanently injured. Any thus affected had best be uprooted forthwith, and new plantations formed from the runners pricked out in reserve beds last autumn. Of course no fruit can be expected from such plants during the present season, but the best runners for next season's forcing may be obtained from them, so that they will be of some service if planted thus early. Figs that have been matted or coiled up with hay bands for the winter may now be uncovered, but they should be nailed at once or tied closely to the walls to be clear of frost. Thin out any weak or unripe shoots, but avoid cutting them more than is absolutely necessary for the full exposure of all the branches to light and air. If the trees are in full bearing vigour use manure freely over the surface; but if strong-growing and shy as regards fruiting, partially root prune by taking out a trench at a reasonable distance from the stem, and cutting off a few of the largest roots; then fill in with the same soil without any admixture whatever. Keep all strong growths constantly pinched during the summer, and this, with impaired root action, will conduce to fruitfulness another season.—W. W.

Kitchen Garden.

Now that favourable weather has set in all vacant ground should be dug and all crops of a doubtful character, such as frost-bitten Lettuces, Broccolies, Cabbages, Globe Artichokes, &c., should be removed. Parsnips and Carrots that have been wintered in the ground should also be got up before they start into growth, and the ground can then be got in readiness for other crops. Celery already manifests a tendency to bolt, and, where such is the case, it is best to lift it and heel it in under a north wall, an operation which not only retards the Celery, but sets the ground which it has occupied at liberty for Peas, Potatoes, and similar crops. Winter Spinach, though much damaged, is, with the two or three milder days which we have had, starting into growth, and this crop may therefore be left till the Spinach, now to be sown, is ready to pick. It may then be dug into the ground as manure, and the plot set apart for Potatoes or the earliest batch of Broccoli, either of which do well as a successional crop to Spinach. Seed sowing will now be the most pressing operation, and a suitable seed bed being the first stage of the ladder, neither labour nor patience should be spared in preparing it. Light soils need little beyond well firming in order that the drills may be drawn neatly, but heavy soils will require the surface to be worked about on fine days, and the drills to be drawn a couple of days or so prior to putting in the seeds; if the drills, too, can have a coating of lighter soil or the seeds be covered in with such, the success of the crops will more than compensate for the extra labour. Considering the fickle character of our spring months it is yet too soon to plant the general stock of Potatoes, though, considering the liability to disease when the tubers are late in maturing, one hardly knows which is the greater of the two evils, that is, the haulm to be cut down with spring frosts or the tubers destroyed by murrain. In any case, I would recommend the risk to be made of planting a good breadth of the first early kinds, and, as soon as the tops show above ground, draw the soil over them, and when this can be no longer done cover them with long stable litter till all danger from spring frost is over. If the ground be dry and has been deeply trenched or dug, dibble the sets in in preference to planting them in drills, but in wet or tenacious soils drill planting is preferable because the sets can then be covered, as they should be, with dry mould or vegetable refuse, such as leaf soil, the ashes from refuse heaps, and similar material, all of which assist in the production of clear tubers. Preserve the straightest medium-sized old roots in Seakale that has been forced, for the purpose of forming new plantations, work which may now be done, as cuttings are forthcoming for the purpose. Cut them into lengths of from 4 in. to 6 in., and plant them in rows 2 ft. asunder and 18 in. apart in the row. A long dibber is the most convenient implement for the purpose, and the tops of the cuttings should be covered with at least a couple of inches of soil. Of course the deeper and richer the ground is, the finer will be the Kale to be had for forcing next season. Horseradish may be planted in exactly the same way, but such a plantation should not be used for a couple of years. As regards forced vegetables, Rhubarb will now need little beyond the crowns being covered with pots, to keep up a constant supply. Seakale, also, will readily start into growth by covering the crowns with cinder ashes, or old tan, and the Kale is sweeter when thus produced than it otherwise would be. When there is no provision for forcing Asparagus on the ground, such as frames or pits, another batch must be lifted to

maintain the supply till the open-air produce is ready. French Beans will now do best if sown in a pit or frame, such as that from which the earliest Potatoes have been dug. A slight bottom heat, and a top heat of 60°, are all that is required. Sow thinly in rows a foot apart, and earth up with light rich mould as growth proceeds. To Carrots, Radishes, Potatoes, and Canliflowers, air must be freely given whenever the weather is favourable; the latter will "button," if kept too close or crowded. W. W.

Extracts from my Diary, March 10 to 15.

Thinning Grapes. Shifting Strawberries that are set from Muscat house into Melon house, to swell their fruit. Digging ground lately cleared of Celery for Onions. Sowing west border with Carrots. Sprinkling with artificial manure, cultivating and drilling south border for Potatoes. Putting in Muscat Vine eyes. Propagating Verbenas and Ageratums. Sowing Lobelias and Schizanthuses. Earthing up Potatoes in frames. Sowing east border with Student Parsnip and James' Intermediate Carrot. Planting south border with Alpha, King of the Earlies, and Early Hamsworth Potatoes. Planting first batch of Melons. Tying Tomatoes in fruiting pit. Tying Cucumbers. Potting Ferns. Sowing first batch of Turnips between Rhubarb. Sowing first batch of Celery. Putting lights on Peach wall as protection from frost. Staking Peas in boxes in cold houses. Hoeing and cleaning Asparagus beds. Sowing Pyrethrums. Thinning Mignonette in pots. Putting in Vine eyes, consisting of Gros Colman, Duke of Buccleuch, Pearson's Golden Queen, Canon Hall Muscat, and Bowwood Muscat. Sowing Begonia seeds. Staking and tying Roses. Getting in another batch of Asparagus into Mushroom house. Tying and stopping Vines in Hamburgh house, first time. Tying up Vines in Muscat house. Propagating Begonias. Planting Magnam Bonum, Ripley's Seedling, Haigh's Seedling, Old Lapstone, and Uxbridge Kidney Potatoes. Pruning and nailing Pears and Morello Cherries. Forking twich out of Asparagus beds. Getting Roses, Dentzas, &c., that have been forced from cold houses to the open air. Shifting pot Vines. Potting Gloxinias, Calanthes, and Calceolarias. Pruning and nailing Pears. Protecting Peaches on walls with netting. Staking Pyramid Apples; also first crop of Peas outside. Potting a batch of French Beans. Clearing ground of Brussels Sprouts, &c. Making new lining to hotbed in frames. Sowing Poinsettia seed and a pan of Lavender. Clearing off and cultivating ground for Potatoes, and giving it a top-dressing of old sawdust. Potting next batch of French Beans. Planting International Kidney Potatoes. Emptying Fine store of Rhubarb for pot Vines. Making fresh lining to pit for Pines. Thinning Grapes. Tying Peaches in early houses. Pruning and nailing Cherries and Figs on east wall. Planting after Brussels Sprouts early Vermont Potatoes for seed, also a few single rows of different varieties for stock only. Tying, stopping, and disbudding Vines in Hamburgh house. Thinning Grapes in pot Vinery. Putting a little soil over Peas in pots in cold houses. Making a fresh Cucumber bed in the Pine stove. Getting half-hardy plants out of span-roofed house. Re-arranging plant houses.—R. GILBERT, Burghley.

NOTES FROM KEW.

Greenhouse Plants.—Another addition to the lovely Himalayan Rhododendrons mentioned last week is a silvery-leaved kind (*R. argenteum*), which is remarkably handsome and distinct. The plants are from 6 ft. to 10 ft. in height, and have leaves nearly 1 ft. in length and proportionately broad, their under surfaces being silvery. The heads of bloom are very large and dense; the individual flowers, which are bell-shaped, measure upwards of 2 in. across the mouth, and vary in colour from a pale sulphur-white to a delicate pink, with a central dark blotch. It inhabits the lofty mountain peaks of Sikkim, where it forms with many others a very striking feature in the landscape, often growing 30 ft. high. It first flowered in this country (at Kew) about twenty years ago. The yellow-flowered *Chorozoma* (*C. flavum*) is an elegant little Australian shrub, with small, Holly-like leaves, and it is a desirable kind on account of its distinct colour, as the majority of *Chorozomas*, though they differ in foliage, bear flowers which strongly resemble each other. The charming little single-flowered *Milla* (*Triteleia*) *uniflora*, a native of Buenos Ayres, associates admirably with other showy plants, the stae-like, pale purple blossoms, abundantly produced, being highly attractive. It is scarcely necessary to add that this desirable bulbous plant is perfectly hardy, and that, ere long, it will help to enliven outside borders. It is very variable in point of colour, for, even in a small batch, some marked varieties may be detected, and two in particular deserve notice, viz., conspica, of a deeper shade than the type, and lilacina, with conspicuous violet-blue stripes down the centre of each division. *Eriostemon*, when covered with pure white, star-shaped blossoms, nearly 1 in. across, are very showy. Two kinds now in flower closely

resemble each other, viz., *E. cnepidatum*, with narrow and sharply-pointed leaves, and *E. myoporoides*, with the leaves much broader. *Cytisus filipes*, a shrub growing from 3 ft. to 4 ft. high, of a very gracefully drooping habit, is well adapted for interspersing with plants of rigid growth, the branches are long, very slender, and leafless, and are covered for the greater portion of their length with small white blossoms. *Viburnum suspensum*, a Japanese shrub of no great beauty, is desirable for the sake of variety. It is of dwarf growth and produces numerous clusters of whitish blossoms, resembling those of the common *Laurustinus*. The huge plant (40 ft. high) of the New Holland Silver Wattle Tree (*Acacia dealbata*) is now splendidly in blossom in the Temperate House. The profusion with which the clusters of golden blossoms are borne, added to the elegant silvery foliage, renders it one of the most desirable of the numerous family to which it belongs. It is, moreover, extremely useful for cutting purposes, as it lasts in good condition for a considerable length of time.

Orchids.—Though an old introduction, and now tolerably common in gardens, but few *Dendrobies* can rival *D. Devonianum* for beauty and gracefulness. The flowers, which are about $\frac{1}{2}$ in. across have a large, roundish lip, beautifully fringed at the margins, and furnished with a large central yellow blotch which contrasts finely with the delicate bluish tint of the other parts. These are plentifully produced on long, slender, pendulous stems, on which account it is best adapted for basket culture. It inhabits the Khaysa Hills and other places in North-east India. Scarcely less beautiful, and now apparently becoming rare, is *D. mutabile*, better known, perhaps, as *D. tridenum*, a continuous blooming kind, but more freely at this season than at any other. The flowers, which are rather small, are white, sometimes with a rosy tint and a bright orange spot in the centre, and they are borne in clusters 3 in. long. It is a native of Java. Of quite a different style of growth is *D. densiflorum*, which has stout, erect stems terminated by two or three leathery evergreen leaves. The clusters of blossoms are very dense and of a bright orange colour, but, owing to their short duration, this *Dendrobe* will never become such a popular favourite as many of its congeners. Except for the delicious perfume of its flowers, the Crisped *Rodriguezia* (*R. crispata*) is scarcely worth consideration, as the blossoms are of a dull green unattractive appearance. The same may be said of the curious little *Notylia notialis*, though it possesses a more aromatic fragrance than the preceding, much resembling that of *Cowslips*. It has been aptly remarked that the Lily of the Valley amongst Orchids, is *Odontoglossum pulchellum*, as the chaste beauty of its waxy, pure white blossoms, mingled with the deep green foliage, at once reminds one of that flower. The variety called *majus* is superior to the type in point of size, if that be a recommendation, but both well deserve to be accommodated even in the choicest collection. The rosy *Odontoglossum* (*O. roseum*) possesses a colour rarely seen in the genus, viz., a deep rose, that renders it highly desirable, being about the size, form and colour of *Mesopidinium vulcanicum*, but it may at a glance be distinguished by its different habit. *Chysis Thorswaldseni* produces remarkably handsome flowers, 2 in. across, white, with a golden dash on the lip, and the whole flower of very firm texture, though apparently it does not hold its beauty long. The Crested *Coleogyne* (*C. cristata*) is a general favourite and has but few rivals in that numerous family. The pure whiteness of its large flowers, relieved by the bright yellow crest, contrasts admirably with the deep green leaves which invariably accompany them, and set them off to advantage.

Stove Plants.—In the Palm house, the large-leaved *Clavija* (*C. macrophylla*) is now very attractive. It is a stately shrub about 10 ft. high, with a naked, erect stem terminated by a huge head of ample foliage. The flowers are small, somewhat globular, of a bright orange colour, and borne in long pendulous racemes which are abundantly produced from the axils of the leaves and also from the naked stem. It is a native of Brazil. Near this is another handsome flowering shrub, viz., the Myrica-like *Cyclonema*, a member of the Verberna family and a native of the eastern coast of Africa. It is about 3 ft. high, with heart-shaped, coarsely-toothed leaves, from the axils of which spring numerous loose clusters of blossoms which resemble in form those of a *Clorodendron*—white suffused with pink, and a clear blue, lip-like, lower petal. *Higginsia Ghiesbreghtii* is remarkable more for the rich velvety hue of its reddish-purple, lance-shaped leaves than for the beauty of its blossoms, which are produced in dense clusters at every joint on the stem, and comparatively inconspicuous. As a fine-foliated stove plant few can surpass it, and it is for this purpose that it is strongly recommended. *Crinum ornatum* is a lovely tropical, bulbous plant which, besides possessing a stately habit, has long, bold foliage. Its flower stem rises nearly 5 ft. in height, terminated by an umbel of about a dozen large blossoms of a delicate bluish tint and sweet scented.—W.

NOTES OF THE WEEK.

Saxifraga Burseriana.—This charming Saxifrage is now in bloom in Messrs. Henderson's nursery at St. John's Wood, both in cold frames and in the open air. Small plants of it in 3 in. pots, sheltered from rain and snow, bear eight or nine beautiful snow-white blossoms, each nearly as large as a shilling. In any sunny border or on rockwork this Saxifrage grows freely, and flowers most profusely; and it would also be quite at home in a cold house, where secure from snow and rain its beauty would be unimpaired.

Snowdrops on Stonecrop.—These prettiest of all our early spring flowers have come up from the heaving down which they had by the heavy snow looking as fresh as ever. I have some now in full bloom on a carpet of green *Sedum*, and the effect is most satisfactory. I shall plant with them next autumn bulbs of the Siberian Squill, as these are much cleaner on a carpet of this kind than when growing out of the soil without such protection.—A. D.

Rhododendron myrtifolium.—This is well worth growing in quantity for early flowering, where cut blooms or attractive conservatory plants are required. It is compact in habit; its flowers, which are as small as those of a *Kalmia*, are of a delicate pink colour, and being produced in close trusses, are very convenient for cutting. It is grown by Messrs. Osborn, of Fulham, in whose nursery it is now in flower.

Masdevallia Veitchii.—Like most other Orchids, this varies greatly both in the size and quality of its blossoms. The best variety of it which we have yet seen is now in flower in one of the Orchid houses at Gunnersbury. The size of the bloom is larger than that of any other *Masdevallia*, whilst it is perfect in form and indescribably brilliant.

Apelandra aurantiaca Roezli.—This is grown in quantity by Mr. Roberts at Gunnersbury. The plants, which are in 6 in. pots, are bushy, well furnished with marbled leaves, and produce large quantities of spear-like heads of brilliant scarlet blossoms. Though of little value for furnishing flowers for cutting, plants of this *Apelandra* are very useful, and have a handsome appearance in vases or for furnishing the front rows on conservatory stages.

Rhododendron Falconeri.—This, one of the finest of the Himalayan *Rhododendrons*, is now in flower in Messrs. Downie & Laird's Winter Garden at Edinburgh, where it is bearing no fewer than thirty-nine trusses of beautiful, large, creamy-white blossoms. The plant in question is some 7 ft. in height.

Old Azaleas at Fulham.—The old and excellent plants of Ghent Azaleas, for which Messrs. Osborn's nursery has long been noted, promise this year, in spite of the late severe winter, to bloom equally well as in former years. The buds are very numerous, and have not suffered the slightest injury from frost, thus showing that these charming flowering shrubs may be planted with safety even in the coldest districts.

Hardy Plants in Flower at Tottenham.—Among the best of these may be mentioned *Saxifraga Burseriana*, *Crocus Imperati*, *C. Olivieri*, *C. Sieberi*, *C. biflorus*, *Muscari Scavittianum*, *Hepatica angulosa*, *Cyclamen*, and several varieties of *Hellebores*; *Narcissus Clusii*, *Fritillaria pudica*, and *F. Kroleini* are also in bud. Indoors the *Lachenalias* are very gay, especially *L. quadricolor*. I have had them in flower since October. *Begonia Frobellii* is magnificent. What a grand winter-flowering plant it is! *Hamamthus cinnabarinus* is also very showy, but not hardy. *Primula erosa* and *Imantophyllum miniatum* are also in bloom.—A. P.

Camellias at Fulham.—A large house devoted to these in Messrs. Osborn's nursery at Fulham is now very gay, many plants, consisting of the best known kinds, being profusely in bloom. The plants are of home growth, very vigorous, and are in every way preferable to those of foreign growth, the blooms being larger and more perfectly developed, whilst the buds are less liable to drop. Over the *Camellias* are trained *Tea Roses*, a plan which shows us how charming a house can be made by means of such a combination. If the *Roses* be trained close under the glass, and not allowed to get too thick, they would afford that partial shade in which *Camellias* delight.

Dendrobium Ainsworthii.—This is, without doubt, the best of Hybrid *Dendrobes*, and of this, even, there seems to be inferior as well as fine varieties. The best which we have yet seen is now in flower in Messrs. Veitch's nursery, Chelsea, where it originated from a cross, made by Mr. Seden, with a fine variety of *D. nobile* *coeruleum* and *D. heterocarpum*. The flowers are larger than those of any other *Dendrobe* in the section to which this hybrid belongs; its petals are of fine form, broad, waxy, and pure white, set off to

advantage by a rich dark purplish-crimson throat. Inferior varieties, under the same name, in the nursery just alluded to, and which originated elsewhere, the result of a similar cross, were obtained from varieties of an inferior quality in the first place, thus showing that in cross-breeding there is a great advantage in selecting the very best varieties of the species which are to be the parents.

Galanthus Imperati.—This fine new Snowdrop is slightly earlier than either the common or the Crimean Snowdrop. It has larger flowers and longer stalks than the two last-named.—R. P.

Rhododendron Hodgsoni.—This Sikim *Rhododendron*, is, according to the "Irish Farmers' Gazette," finely in bloom at Glasnevin, where it is quite a tree some 12 ft. or 14 ft. high, well furnished, and carrying no fewer than 160 gorgeous heads of rosy-purple flowers. Several other species are also now in bloom in the same house.

Cyclamen coum vernum.—Notwithstanding the inclemency of the weather, this beautiful little harbinger of spring now forms a lovely object on the rockery at York.—R. P.

Azalea viscosifera.—This is one of the best of the Ghent Azaleas for forcing. Its flowers, which are pure white—except that the upper petal is slightly tinged with yellow at its base—are deliciously fragrant, and valuable for bouquets. We saw plants of it in bloom lately in Messrs. Osborn's nursery at Fulham, in company with *A. mollis* and other varieties; also well flowered examples of the common *Gaelder Rose* (*Viburnum Opulus*), *Rhododendrons*, berried *Acunbas*, and forced *buds*.

Orchids at Gunnersbury.—In the fine collection of Orchids in Baron Rothschild's garden at Gunnersbury, are just now several plants in flower well worthy of notice. Prominent amongst these is the rare *Odontoglossum Andersonianum*, bearing two gracefully arched branching spikes, beset with no fewer than 200 waxy, cream-coloured, beautifully spotted blossoms. *O. Alexandræ*, a fine variety, is in equally good condition, the flowers measuring from 4 in. to 5 in. in diameter, of satiny whiteness suffused with violet, the lip being of bright gold marked with brown spots. *O. cirrhosum* is also producing a fine spike of bloom. *Phalænopsis grandiflora*, and *Schilleriana* growing in wooden baskets along the front of one of the houses are likewise very effective, a narrow stage under them being clad with *Selaginella denticulata* and *Panicum variegatum*, which being kept moist serve two purposes—that of giving the house a pleasing appearance, and benefitting the Orchids.

Prizes for Amaryllis.—An amateur, anxious to encourage the cultivation of this tribe of plants, offers the following prizes to be competed for at the Royal Horticultural Society's meeting, to be held at South Kensington, on April 8. The prizes offered are:—A. For the best dark seedling, 1st prize, £2; 2nd, £1; for the best light seedling, 1st, £2; 2nd, £1. No prizes will be awarded unless the seedlings show decided form and substance of bloom. B. For the best six *Amaryllis*, named, three to be dark and three light varieties, 1st, £2; 2nd, £1. The prizes to be awarded only if the exhibits be considered of sufficient merit. Form, substance, and breadth of petal are necessary points. C. For the best variety selected from among the plants exhibited in class B—For the best dark variety, £1; second best, 10s.; for the best light variety, £1; second best, 10s.

Orchids in Flower at Chelsea.—The Orchid houses in Messrs. Veitch's nursery at Chelsea are, at present, very gay, with flowering plants of some of the best and most popular varieties. Amongst others are especially notable *Dendrobium crassinode*, grown in baskets and small pans, and thickly beset with blossoms; *D. Wardianum*, in equally good condition; and specimen plants of the old, but useful, *D. nobile*, growing in pots, are perfect masses of blossom. *D. Farmeri* bears large drooping bunches of white and yellow flowers. *D. Findleyanum* is a very delicate-flowered variety, with violet-tinted petals and lemon-coloured throat. The curious blood-red *Maxillaria Turneri* is also in flower, as is likewise *Angraecum citratum*, the pretty white flowers of which are set in thick rows on the upper side of long, arching flower-spikes. In addition to these are the beautiful Hawthorn-scented *Odontoglossum madrense* and *O. Roezli* roseum and album, fine varieties; the rare *Epidendrum Wallisi* also bears flowers with waxy, cinnamon-coloured petals and white, purple-traced lip. Many *Lycasts* are also in bloom, and *Cattleyas*, of the *Triana* section are well represented. To these may be added *Odontoglossum prænitens*, *O. gloriosum*, *O. Halli*, *O. nevadense* (a kind having flowers with chocolate petals, barred with greenish-yellow, and a white lip), *O. Alexandræ*, and *O. cirrhosum* in great variety.

Lily Bulbs.—I have to thank Mr. Smith for his reply (p. 178), but I differ from him on the subject of the bulbs, as I agree with the writer in the "Californian Horticulturist" (p. 118), as regards "the decay of the old bulbs and the formation of new ones internally."—B.

ANSWERS TO CORRESPONDENTS.

Evergreen Ferns.—Can any correspondent kindly give me a list of a few medium-sized evergreen Ferns, whose fronds will not turn yellow during the months of December, January, and February in a greenhouse where the temperature ranges from 46° to 56°, as almost all of mine have done at the very moment when they were required for table and other decoration.—D. [The following Ferns, suitable for a cool or intermediate house will be found, if properly treated, to be in good condition during December, January, and February, and other dull parts of the season, viz., *Asplenium Belangeri*, A. bifurc., A. lucidum, *Aspidium cespense*, A. falcatum, *Dicytogramma japonica*, *Gleichenia semper-virens*, *Gymnogramma Massoni*, G. Calomelanos, *Nephrodium glabellum*, *Nephrolepis undulata*, *Oncophyllum japonicum*, *Polypodium sub-aureum*, *Todea barbara*, *Woodwardia radicans*, and *W. r. cristata*. All these have bright clean-looking foliage.—J. B.]

Zonal Pelargoniums for Culture under Glass.—Would you assist me by naming a dozen and a half good Zonal Pelargoniums. I am anxious to add to the greenhouse collection which I already possess, and which is not large. Constant and free bloomers, producing large trusses, are what I am anxious to get, besides being distinct varieties. Would you also name two of the best white kinds? Are *Leamington Lassie* and *New Life* good and free bloomers?—K. T. [The following will possibly answer your purpose, viz., *Mrs. Wright*, deep rose; *Miss Gladstone*, white, with a pink centre; *David Thomson*, brilliant crimson, with white eye; *Sybil H. Eden*, soft rose purple; J. C. *Masters*, purple and crimson; *Circulator*, rosy-scarlet; *Colonel*, Seely, crimson-scarlet, with a white eye; *Lady Sheffield*, violet-purple-pink; *Lizzie Brook*, rosy-crimson; and *Tom Bowling*, orange-scarlet. *Jeanne D'arc* and *White Vesuvius* are two good whites.—H. C.]

Heating Small Greenhouses.—For a house like that described by Mr. L. J. Browne (p. 172) I should recommend a small—say 20 in. long—common saddle boiler as the cheapest, safest, most efficient, as well as most economical, both as regards fuel and attention, that can be adopted. A 24 in. one will heat two houses such as that named. A flued saddle is preferable to the ordinary form where there is work enough for it to do; but they are not made small enough to heat a single house, similar to the one in question, and to have a boiler too large proportionate to the amount of piping attached to it is to incur the certain annoyance of its driving the water in quantity out of the feed cistern when the fire has to be kept going briskly in severe weather. The coil boilers mentioned (p. 176) often do their work fairly well, but I very much prefer a saddle, especially for such places as those under consideration, where, if well set with a roomy furnace, it will burn up anything, and require correspondingly little attention.—T. BAINES.

Cucumbers in Houses.—I am building a little house for Cucumbers, salads, &c., for market, and in the winter to keep bedding plants, as I do not think it will pay to grow Cucumbers in the winter, and being only a garden labourer, I have not much capital. I want, therefore, to grow what will pay best. My house is 12 ft. long and 6 ft. 6 in. broad, lean to against a wall 9 ft. high at the back and 4 ft. brickwork in front with 2 ft. glass, making it 6 ft.; then I get 3 ft. fall for the roof, with glass ends. I think of building a flue along the front for bottom-heat, crossing the end and along the back. Will you kindly tell me whether brick flues or iron pipes would be the best, and what distance should the wires for training the plants be from the glass? and how far apart? Also what is the best Cucumber for the purpose? and how deep ought the bed to be for the mould? and how wide and what distance apart should the plants stand.—C. C. [A flue will answer if you only want to grow Cucumbers during summer, and if this be built in the way you propose, you will get sufficient bottom-heat. The wires should be about 15 in. from the glass, and about 12 in. apart. String will answer the purpose as well as wire. The best Cucumber for the purpose is *Rollison's Telegraph* or *Tender and True*. 6 in. or 8 in. of mould will be enough to plant the plants in, if you earth them up afterwards as the roots appear on the surface of the soil. The plants should be 2½ ft. apart, but you can plant as thickly again as this if desirable, and crop each alternate plant whilst in a young state, destroying them when the rest have become well established. With a flue abundance of moisture must be kept in the house or red spider will soon get possession of the leaves of the plants.—S.]

Names of Plants.—J. W.—*Acacia lophantha*, a native of New Holland. *W. B.*—1, *Nipholobus Lingua*; 2, *Polypodium Billiardieri*; 3, apparently some *Maxillaria*, of which some better specimens should have been sent.

Names of Fruits.—J. D. B.—1, Some local variety undetermined; 2, *Hawwell Souring*.

Questions.

Cutting down Arbutus.—I have an *Arbutus* hedge twenty years old, that is now too high. If the *Arbutus* be cut down close to the ground, or leaving a few feet of stem, will they be likely to sprout again?—E. F.

Eucalypti.—Where can I purchase small plants of *E. amygdalina*, or seeds of it? I find many notices of *Eucalypti* in THE GARDEN, but no mention of where to obtain stock or seeds of them. In several gardens here, the *Eucalyptus globulus* had attained a height of about 20 ft., but the severity of this winter has killed them all. Prince Troubetzkoy reports *E. amygdalina* to have withstood 6° below zero centigrade (21° Fahr.) at Rome. It might therefore succeed in Devonshire.—ΕΞΟΥΤΗ.

Cyclamens.—Some flowers come very jagged and others are small and poor, although grown from the very best seed, and having good bulbs and foliage. Ought I to throw such away, or will there be a chance of improvement if I grow them on for next season? I find *Auriculas* to vary, but I fear a *Cyclamen* once poor is always poor. Can any *Cyclamen* grower give me a word of advice on this subject.—BROCKHURST.

Flower-bed Arrangement.—Can any advise me about a bed I propose making in a hedged-in Grass court. It is to be seen from a distance of 30 ft. My idea is an oval bed 8 ft. long and 5 ft. in breadth, to be planted with *Amila Sieboldi*, *Yucca recurva*, and *New Zealand Flax*, supplemented in the summer with *Coleus* and *Iresine*, and *Centaurea candidissima*, the rest of the bed to be permanent or protected with hurdles or matting next winter. I propose to put in the *Aralias* and *Yuccas* of about 1 ft. high, also the *New Zealand Flax*. But, as I am ignorant of their relative rates of growth, I wish to ascertain how many of each I may require, and how they should be arranged; whether it is indispensable to place the *Flax* in the centre, or whether I should centre the bed with a pillar *Rose*, or a drooping flowering shrub, or one of slender, erect growth. In the latter case what would be the best *Rose* for the purpose, or the best shrub? I do not want *Willow*, *Laburnum*, or *Almond*. The Grass court is oblong, sheltered, moderately sunny, but the soil is heavy, cold, and damp; county, Oxfordshire.—AZUCENA.

THE INDOOR GARDEN.

AMATEURS' GREENHOUSES.

If the thousands of amateurs who possess greenhouses, such as "Delta" (p. 138) describes his to be, were to follow a similar course as regards the plants grown by confining themselves to those they can accommodate in a way calculated to admit of their thriving satisfactorily, there would be less disappointment than there now is. It does not follow that every one with similar accommodation must needs grow the same kinds of plants exclusively. People's tastes and fancies differ with respect to these as with other things. The secret of success with amateurs who rely principally upon their own knowledge in, and attention to, what they cultivate, is to keep principally to such subjects as they can manage, and not attempt more variety than the capacity of the house or houses which they have will permit. This is just what the majority do not do, but, instead, get a bit of almost every plant with which they meet that takes their fancy, until the generally limited room is crammed up to an extent that makes it impossible for all to do more than exist, and when any of the least deserving, it usually happens to be these, get too large the owners have seldom courage enough to clear them out.

"Delta's" practice is also an example of that which I have always urged upon amateurs, viz., the advisability of growing some Grapes in their glass houses, especially where they have two, or one in which there is a division, for, although by real lovers of flowers, the continued opportunity which a greenhouse affords for enjoyment all the year round is often felt to be sufficient for the trouble and comparatively little expense entailed, yet there are few who will not acknowledge that good Grapes are not also always acceptable, and that both these and plants can be grown together equally presentable is evident by what we see continually accomplished. The principal thing to keep in view where both fruit and plants are to be grown together is, that whether one, two, or more Vines are planted according as the size of the house and other circumstances will allow, the roof is not covered to more than half the extent that would be admissible if Grapes alone were grown in the house, and that the plants, which must necessarily stand underneath, have comparatively more room than if there was nothing over them. This precaution, coupled with greater vigilance in looking out for insects, will enable those who like to grow both Grapes and plants to gratify their inclination, even when the means available are no greater than those which "Delta" has. I do not mean to assert that either the plants or the Grapes can be had equal in appearance to those produced under separate treatment, but it is what I should adopt myself under like circumstances.

In respect to the means by which "Delta" warms his house with a flue composed of large drain pipes, it is far from a safe method, as I can testify both from my own experience and the break-downs which I have seen in the case of others who have adopted a similar mode of heating. Even when the precaution had been taken as "Delta" describes, of having several feet of brickwork adjoining the fire before the tiles commence,

and with a strict attention in keeping the pipes swept clean of soot, accompanied by careful stoking, I still found that, as with a brick flue, the soot would nevertheless sometimes get on fire, the invariable result being cracking of the tiles. This occurred when they were made of different descriptions of clay, both glazed and unglazed, and after they were cracked, if the fire charged at all, it generally separated those that were so affected, with the consequent admission of smoke and sulphur, the destructive effects of which it is not necessary to particularise. In my own case, instead of having the pipes round the house continuous, I had in each corner a short length of ordinary flue covered with stone flags, which much facilitated the sweeping process, but from the cause I have named I had them out, and a brick flue put in their place, made, as I would always advise where this system of heating is to be used, with the bricks on bed not on edge, that is, $4\frac{1}{2}$ in. work instead of 3 in. This is so much stronger, less liable to crack, or be shaken and leaky through age, getting on fire, or the furnace charging, that it is much to be preferred; it takes very little longer to get up the heat in these stronger made flues, than with such as are built brick on edge, and the additional substance enables them to retain heat longer after the fire has burnt down, so that the little time which is lost after the fire is lit, is gained in the opposite direction. But, now, when hot water pipes are so easily and expeditiously put together with indiarubber rings, yarn, and red lead, or Portland cement, there is little need for the apparatus costing much more than a flue; and if the furnace for the boiler—a common small saddle is the best in cases of this sort—be made with a view to economy, it will burn up all the cinders and refuse from the fires in a dwelling house. The fire space must be roomy, so that the work can be done on the slow combustion principle, which, to be successful, needs a good body of fuel, as a matter of course, with a damper to regulate the draught. A handy man, such as "Delta" speaks of, with a few hints from any intelligent cultivator who understands this description of work, and who is generally to be found in every neighbourhood, would succeed in putting in a simple hot-water apparatus without much more difficulty than a flue. My reason for here recommending an ordinary saddle in preference to one constructed on the improved principle, with flue and terminal end, is that none of the latter are made but what are much larger than required for one or two small houses, and the price of the common saddles is a good deal less. T. BAINES.

THE OAK-LEAF PELARGONIUM.

In answer to "B. S.'s" inquiry (p. 164) concerning this Pelargonium, I can certainly say that it long survived the "Pig tails" with which "B. S." somewhat oddly associates it. I know not when these appendages went out of fashion, I only remember seeing one some fifty-five years ago at least; but I have met with and grown the Oak-leaf Pelargonium down to a far later period, and I have no doubt that it may yet be found if perseveringly looked after. When I saw the last plant of it I cannot recollect, but I well remember bedding the variety out. It was a great favourite with us before the zonals made their appearance. This Pelargonium cannot well be confounded with any other, and, moreover, it is figured in "Ourtia." "B. S.'s" plant is not, however, *Pelargonium quercifolium*, but *P. glutinosum*. The true Oak-leaved Pelargonium is a much smaller and neater plant, something in the style of the old Moore's Victory, and may be met with in nurseries and gardens under the name of Fair Helen, and is, as regards flower, one of the most beautiful of all the Cape Pelargoniums. Moore's Victory I have not seen for many years, and, like the once famous P. Darynnam, is perhaps lost. It is surprising that the Cape Pelargoniums have not been taken in hand more earnestly than they have been, containing, as they do, some of the most powerfully scented plants known. They also possess an infinite diversity of foliage, and a refined beauty in the flowers of many of them, such as P. ardens and P. echinatum, and, as yet, we have only taken in hand the old P. inquinans, zonale, and lateripes, between which a cross has been effected by Mr. Wills. How rarely now do we meet with the old P. tetragonum, or its variegated form? and who has ever seen the simple-leaved Pelargonium, P. lanceolatum P. What interesting work it would be for some enthusiast to gather together the nearly 300 Cape Pelargoniums with which we were once acquainted! There was at one time a pure golden-yellow Pelargonium, but it is a question whether it now exists or not; this was named *P. luteum*.

There was also a *P. flavum*, with foliage like that of a Carrot. What shades of colour might not be produced with such material with which to work. Imagine a pure yellow Tom Thumb, or a Vesuvius. Many of the Cape Pelargoniums may still be met with, mostly among cottagers, who are fond of such sorts as the Nutmeg, the Parsley (*P. crispum*), the Mint-scented, and others. I ought, perhaps, to add that Mr. Cannell, of Swanley, has the nucleus of a collection of these interesting plants. THOS. WILLIAMS.

ASPARAGUS DECUMBENS.

This makes an elegant basket plant. Its foliage is light and feathery, assuming a gracefully pendent habit, and, being of a pleasing shade of green, when well grown it is effective either in the conservatory or dwelling house. Its blossoms, though small, are sweet-scented, and when in fruit it is one of

Fruiting Spray of *Asparagus decumbens*.

the most interesting of the class of plants to which it belongs. The plant from which the annexed spray, showing the fruit, was taken was sent to us by Messrs. Vertegans, of Birmingham. S.

Propagation of Bertolonias.—Mr. Baines (p. 183) omitted to mention that the leaves afford a very ready means of propagation, as they will produce several plants from each leaf, by simply pegging it down flat on the surface of some light soil, and placing it under the same conditions as recommended for cuttings. This mode is, I consider, far preferable to taking off the half-ripened shoots, particularly as they are not produced very plentifully, and there is less risk of spoiling or at least disfiguring a plant, as the lower leaves, which may have become shabby, will answer the purpose as well or better than the newer ones. B. Van Houtteana, guttata superbissima margaritacea, and others, strike most freely in this way.—W.

"This is an art
Which does mend Nature: change it rather: but
Tis Art itself is Nature."—Shakespeare.

INDOOR FRUIT GROWING FOR MARKET.

FROM Finchley, Potter's Bar, Barnet, and other places in that direction, comes the principal supply of forced fruits to our London markets. The houses in which they are grown are by no means elaborate as regards construction; they are mostly span-roofed, and vary in length from 100 ft. to 300 ft.—strong, light, and airy. They are, as a rule, efficiently ventilated and well supplied with hot-water pipes, the latter being equally distributed about them, thus obviating the necessity of making them so intensely hot—even during cold weather—as to produce bad results from attacks of red spider, a pest dreaded more, perhaps, than any other by the fruit grower.

GRAPE.—These are the most important of indoor fruits, and by many pronounced to be the most profitable. Much, however, as has been before stated in regard to other crops, depends upon having them ready for market just at a time when they are most required. The rapidity with which Grape culture has extended during the last few years is something surprising, and that it is still on the increase is apparent by the number of glass houses that we see almost daily springing up in London and its suburbs. Even at the back of villa residences, where a few yards of ground exist, may frequently be seen numerous small houses devoted to the culture of Grapes, either for market or private use. Our imports of foreign Grapes during the summer, though great, do not appear to affect in any material degree the interests of English cultivators; for, unless imported fruit be of fair quality, its cheapness will by no means guarantee its sale in London markets. From the Channel Islands we receive large consignments of first-class Grapes much earlier in the spring than it would pay English cultivators to produce them; but, after the end of May, by the aid of cheap and improved appliances, and increased knowledge of their business, growers near London who can cut their Grapes and take them forthwith to the salesman, can compete on equal terms even with the Jersey cultivators, notwithstanding that the latter have the advantages of a milder climate and purer atmosphere. I have often been informed by London Grape growers that it is possible to produce fruit of good quality, during the summer and autumn months, at 1s. 6d. or 2s. per lb., with profitable results. But for all this, the enormous profits required (perhaps necessary to meet the heavy losses often sustained) by the retail vendors render it impossible for the public to reap the advantages of cheaply-grown fruit. During the winter months, when Grapes, as a rule, realise the highest prices, if the cultivator obtains for fruit of the highest quality, 6s. or 8s. per lb., he thinks himself well paid, and yet the retail price often reaches from 18s. to 20s., and even 25s. per lb. But at these prices the demand for Grapes is ever on the increase, and growers having a great extent of glass devoted to Vine-culture find no difficulty in disposing of their produce. In one of the most important Grape growing establishments near London there are seventeen large houses entirely devoted to Grape culture, and, collectively, these houses contain no fewer than 650 canes, the majority of which are in excellent fruiting condition. At one time the Vines

here were planted in outside borders, or, if planted inside, their roots were allowed to ramble outside, but now they have nearly all been placed inside, in newly-made borders. The latter are of limited extent, but well drained; they receive liberal top-dressings of good yellow loam yearly, and are copiously supplied with manure water during the season when the Vines are in active growth. Shanking rarely occurs in any of the houses here, and should anything be found to be the matter with the roots, owing to their being inside and almost as comestable as the branches, it can soon be remedied.

In making a new Vine border, just enough soil is provided to plant the Vines in the first year, more being gradually added as required until the whole of the border space is filled. By this method the soil is kept in good tilth for a much longer period than would be the case were the borders wholly made at the commencement. The kinds principally grown are the Black Hamburgh, Gros Colman, Madresfield Court, and Muscat of Alexandria. Late Grapes are looked upon with disfavour, it being thought that the expense incurred in keeping them during winter is greater than the extra money obtained for them. The aim, therefore, is to have all Grapes ripe by the middle of September, and marketed as quickly as possible. The earliest houses are planted with Black Hamburgh and Muscat of Alexandria, the fruit of which is usually ripe by the middle of May. Very early Grapes seldom pay for the fuel needed to produce them, inasmuch as the demand for new Grapes before the beginning of May is comparatively small, and the prices unremunerative. Indeed, it is a singular fact that in some seasons Grapes ripe in April only realise from 10s. to 12s. per lb., whereas a few weeks later they fetch double these prices. This is owing to what is termed the London season not having fairly commenced in April. Madresfield Court is sometimes fit for sale in August and September, and sometimes earlier, and it is highly appreciated in the market on account of its jet black colour and excellent flavour. I have seen magnificent basketfuls of it exhibited in the Central Avenue, Covent Garden, supplied by Mr. Wilmot, of Isleworth, and they invariably realised higher prices than any other kinds, Muscats excepted. As an early Grape, too, this is found to succeed well, and the examples of it shown in May at some of the London shows have been simply magnificent. Good strong, established canes of average length are generally allowed to carry about twenty bunches each, and, as there are upwards of 400 such canes in the establishment referred to, it will be seen that the quantity of Grapes yearly cut for market is very considerable. In pruning, the Vines in question are not cut in so closely as we often see them done in private gardens, but a good plump bud is always left to each spur, and in some cases pieces of young wood 20 in. in length are left to take the places of spurs that fail to break. No plants of any kind are to be found in Mr. Wilmot's Vineries, except, perhaps, a few Tomatoes and Capsicums in pots, it being perfectly well understood that, in order to grow Grapes well, houses must be entirely devoted to them. Cow manure and soot steeped in water form the principal stimulants used in the Isleworth Graperies.

At a large fruit-producing establishment at Potter's Bar, Grapes are grown to a large extent—a fact which will be understood when it is stated that a supply of excellent Grapes is obtained from April till the following March, or at least nine months out of the twelve. The varieties grown are Black Hamburgh for early fruit, and Gros Colman, Lady Downes, Black Alicante, and Muscat of

Alexandria furnish the mid-season and late supplies. The principal Vinery is a span-roofed one, 200 ft. long and 20 ft. wide. The Vines are planted inside, and the roots are allowed to run both inside and out, but no pretentious border has been provided for them. Their main stems are trained under the roof in the form of arches, and when loaded with fruit present a sight unusually interesting. From this house one year 2000 bunches of ripe Grapes were cut. Vine borders here receive little attention beyond being forked up and manured in spring, the soil being simply that of which the garden consists, which is of a yellow clayey character. In autumn, when the Vines need but little nourishment, the borders outside are planted with Broccoli or similar vegetables that can be removed before spring, when the Vines require to be again started. Heavy mulching and feeding when they are in full fruit, and when they require nourishment most, are the principal points depended upon, it being maintained that, whilst at rest, the ground can be turned to profitable account in the way just named without injury to the Vines. In a span-roofed house, 100 ft. long, planted with late sorts, no border whatever was made in which to plant the Vines; a sunk path was simply cut through the centre of the ground on which the house stands, and the Vines were planted on each side, the main stems being trained up one side and down the other alternately; each of these are allowed to carry twenty bunches, with the form and size of which any Grape grower might well be satisfied. As regards pruning, the spur system is the plan adopted. No more fire-heat than is necessary is used, but in autumn, in order to finish the fruit properly, a brisk heat, with plenty of air, is applied to all Vines on which any fruit is hanging. Grapes are cut for market three times a week; each time all bunches which are perfectly coloured are cut and placed stalks upwards in baskets, which hold about 8 lbs. each.

On some occasions 1 cwt. of ripe Grapes is marketed from this place at one time, these supplies, as has just been stated, being obtained during the greater part of the year. As soon as the Vines have been cleared of fruit the houses are closed for a few days and the syringe vigorously applied to the foliage to clear it of insects, &c., after which as much air as possible is admitted, and the roots receive a thorough soaking with water in order to plump up the buds and retain the foliage in a healthy state as long as possible, for, whilst the fruit is ripening, water is, to a great extent, withheld, in order to improve the flavour and solidity of the berries; the roots, consequently, often get very dry before the crop is cleared, and hence the necessity of a good supply of water afterwards, a point probably too often overlooked by Grape growers. A house planted fifteen months before my visit with small canes of Duke of Buccleuch, and only allotted a border about 2 ft. wide, yielded some sixty-four good bunches of Grapes. The rods were planted closely together and fed with manure water, a system on which it was proposed to grow other Vines. The owner has lately planted a house 150 ft. long with young canes of Black Hamburgh for furnishing an early supply; this house, which is of singular construction, was originally intended for Cucumber culture, but as these did not succeed in it so satisfactorily as could have been wished, it was converted into an early Vinery, a purpose for which it is considered admirably adapted. It is 20 ft. wide, and the roof, which is supported on side walls 3 ft. in height, is flat, 9 ft. fall lengthways in the roof only being allowed to throw off water. The interior arrangements consist of a series of beds, some 10 ft. wide and 15 ft. long, surrounded by low brick walls; between each

of these beds are narrow paths, and also one the whole length of the house, on one side of which is likewise a bed 3 ft. wide, also the length of the house. In the centre of these beds the Vines are planted 3 ft. apart, and trained upwards, and when well established, good results in the way of large crops of Grapes may be reasonably expected. The beds are planted with Melons, chiefly for seed; these, it might be thought, would greatly exhaust the soil, but this is easily counteracted by heavy manuring, mulching, and copious supplies of manure water whilst the Vines are in active growth; when the Melons have been cleared away, during winter this house is filled with bedding plants. In spring it is used for Strawberries, and thus the whole space is kept fully occupied.

C. W. S.

(To be continued.)

FLAVOUR OF STRAWBERRIES UNDER GLASS.

An impression exists that Strawberries ripened under glass are uniformly inferior in flavour to those grown in the open air, but I do not hesitate to affirm that, in two seasons out of every three, Strawberries under glass are better flavoured than those grown in the open ground. In many establishments it is the custom to get ripe Strawberries as early in the season as possible, and when ripened in March, or even in April, almost entirely by means of fire-heat, oftentimes with but little aid from the sun, they are naturally deficient as regards saccharine matter. The greater portion of those, however, who devote a part of their glass to forwarding this fruit are well content if they can obtain Strawberries during the month of May. By that time the power of the sun is fully felt, and it often occurs that more favourable conditions then exist for the perfect development of the saccharine properties of the Strawberry than later in the season when the ripening takes place out-of-doors. Nothing can be more delicious than this fruit when well ripened, and nothing is more insipid when it is coloured—for one can hardly say ripened—under unfavourable circumstances. Being naturally of a watery character it requires a large amount of heat and light to thoroughly solidify and mature it; at the same time it demands a considerable quantity of water during the growing period, which, if withheld, has the effect of diminishing the secretions, and consequently deteriorating the flavour of the berries. The latter conditions may, in the case of outdoor plantations, be supplied at will, but the heat and sunshine are not always realised in our fickle climate; the expectations of a fine crop are often blighted by a period of wintry weather or heavy and continued rains at ripening time. Then, again, we often experience chilling weather when the plants are in full growth and when the fruit is swelling. Anything which tends to weaken the general health of the plant will extend its influence up to and during the ripening time. First-rate fruit can only be obtained from vigorous plants, and our spring weather often fails to induce that luxuriance which is so necessary.

These vicissitudes may all be guarded against under glass, sufficient water can always be administered, whilst excess may be guarded against. Artificial heat judiciously employed will insure a temperature necessary to promote a healthy and active state of the organs of nutrition, in fact, we simply modify and ameliorate our climate, just hitting that happy medium which is the very keystone of success. It may be safely affirmed that few, even of those who make a point of annually consuming a considerable amount of Strawberries have really enjoyed this fruit in perfection. With specially prepared fruit I have often surprised and gratified lovers of the Strawberry, and when, as has often occurred, the only experience of its flavour has been derived from open-air fruit, the surprise has been still greater. Anyone who wishes may easily convince himself of the superiority of fruit grown under glass. Let a portion of the crop be covered when commencing to colour with light sashes, and let them remain day and night until the fruit is coloured. The first fruits will, of course, have lost their gloss and will be rather diminished in weight. But the flavour! That will recompense anyone for the slight loss of weight and the exercise

of patience. I once covered some in this manner, then more for the purpose of preserving them from accidents than anything else, as they were wanted for a particular purpose. The season was very hot, and that year outdoor fruit was good, but that under the glass even better; indeed, they were the richest and most highly flavoured Strawberries I ever tasted. The great heat and drought had eliminated the greater portion of their watery character, so that there was not the suspicion of acidity in them. Thus managed, British Queen and President are superb. If in May pot plants be so placed that the fruit can be kept on them some time after it is coloured, at the same time diminishing the supply of water and giving free air during the day, not even taking it off on mild nights, the result will be a treat to the grower; and if he has hitherto cherished an unfavourable opinion of the merits of house-grown Strawberries, he will be ready to admit his error.

It must be remembered that a Strawberry is no more ripe when first coloured than is a Grape; it requires some days—sometimes, in dull weather, a week—to attain perfection. In the open air this condition is but seldom attained, owing either to the impatience of the grower, or to vermin of some kind attacking them. Unless the season is hot enough to thoroughly warm the soil, the under side seldom ripens, and the only way to ensure perfectly ripened fruit is to prop up each truss on sprays of Birch; sun and air then have full play around them, and they ripen right through. The only objection to this method is that the berries are liable to scald if brought up suddenly from the shade of the foliage and exposed to hot sunshine. Under glass this objection does not hold good, as the fruit seldom burns when brought up as soon as it is fairly swelling. Those who grow for market gather the fruit when most saleable, and that is as soon as it is coloured, and is fresh, plump, and bright. Apart from the fact of wishing to pick as early as possible, the berries are then at their heaviest; leaving them after they are coloured in a hot sun means loss of weight. Whoever grows to gratify their own palate will naturally prefer quality to quantity, and will not mind exercising a little patience to ensure it. One season's trial, whether it be hot or cold, wet or dry, will suffice to convince the most sceptical that highly-flavoured Strawberries may be grown under glass.

Byfleet.

J. CORNHILL.

PRUNING, TRAINING, AND PROTECTING APRICOTS.

THE branches of Apricots should be kept close to the wall. If both natural and artificial spurs be permitted, the latter should never be allowed to become large; they project too far from the wall, and in a bad season scarcely any kind of protection will save the fruit on them. Young wood should be encouraged as much as possible. Where natural rather than artificial spurs are mainly relied on, both blossoms and fruit must be nearer the wall and under the immediate influence of its warm dry, surface. In trying to renovate old full-grown trees, the removal of old spurs and the encouragement of young wood should go on gradually side by side; thus no check or disorganisation will take place. New life and vigour will often be infused into old trees by thinning out some of the medium-sized branches, and filling up the space with young wood. This plan need not be resorted to so long as the crop produced is satisfactory; but where Apricots have been an uncertain crop, a change of system will not, under any circumstances, involve much sacrifice, and it may result in a decided success. The great object should be to encourage the production of young wood, and to lay in as much of it as there is space for without crowding. In connection with this, disbudbing in spring should be brought more into a regular system. To lay in more wood without reducing the number of the young shoots by disbudbing the weakly spray would be futile, and would lead to the leaves and branches injuriously shading each other; unripe wood would follow, and the result would be weakly blossoms, which would stand no hardship of wind or weather.

Though a tree should be trained close to the wall to secure full benefit from its warmth, it should not be braced up too tightly. Gumming is often caused by tight ligatures, or by a badly-placed nail injuring the bark. All ties and shreds should

fit loosely, to give space for the branches to swell; no nail should be driven in close to a branch, and no more nails or ties should be used than are necessary to keep the branches safely in position. Where a tree has been well cared for from its youth upwards few nails will, generally, be required, as, when the branches have been properly disposed from the first, the work of training afterwards is very much simplified. The fan system of training is the best for Apricots. When carefully carried out it leads to a better, more regular distribution of the sap; admits easily of any slight alteration of any branches that may be taking the lead during the first years of the tree's formation; and afterwards, should a branch die unexpectedly, the loss can easily be made good. In selecting trees from the nursery care should be taken that the stocks on which they are worked are in a good, sound, healthy state.

As to protection, it is well known that healthy trees, carrying strong, well-matured, fertile blossom buds, will bear more exposure to cold without sustaining injury than those deficient in strength and vigour. Every wall for fruit trees should have a good sound permanent coping of stone, projecting at least from 3 in. to 4 in. from the wall, and it should be grooved underneath, near the edge, to collect the water; it will also be a great advantage if under this groove can be fitted a small sheet iron or zinc gutter to carry off the water and prevent it dripping on the trees. A good projecting coping keeps the wall dry and sound, and trees will thrive much better on a dry, warm wall, than on one that is constantly damp. As regards further protective measures, every season's experience still further convinces me that as good results can be obtained by using simple, inexpensive materials as by the aid of those of a more elaborate and costly character, with the exception of a good glass structure. Light feathery sprays of Yew tree, with the thick ends stuck in under the branches of the tree, projecting from the wall in a downward direction, will afford good shelter from cold winds, and keep off cold rain and sleet. By keeping the light ends of the sprays pointing downwards, the snow and rain will be precipitated to the ground beneath, instead of being conducted to the wall, which will be the case if they have an upward tendency. In windy places an ordifishing net may be drawn over all, to keep the wind from blowing the sprays of Yew from the wall or injuring the blossoms by waving. One advantage of this simple mode of protection is that, as the season advances and more light is required for the swelling fruit, the leaves of the Yew branches shrivel and drop. Where nets of a thicker substance are used, or canvas, or if any other system of covering be adopted that requires removal in the morning and replacing at night, the borders frequently become so trodden in wet weather as to be a serious detriment to the well-being of the trees. Many trees, through injudicious protection in spring, are weakened in health, and rendered more liable to insect attacks. E. H.

FRUIT CULTURE FOR MARKET.

"C. W. S." (p. 199) says that "both for hardy and indoor fruits there is always a ready sale." On the next page, however, it appears that "in a plentiful year hundreds of bushels of good Plums, Apples, and similar fruits, are allowed to rot because the market is so well supplied from abroad that they would not pay for the gathering." This statement implies that our home-grown fruit is inferior to that from abroad, or that foreign fruit of equal quality can be imported at a cheaper rate, or that there is a prejudice in favour of foreign grown fruit, resulting from its superiority or cheapness, better distribution, or some other cause. It is not to be so much regretted if foreign produce of superior quality can be imported cheaper than we can grow it at home, provided the land we have can be put to a more profitable use. The consumers, who are by far the largest class concerned in the matter, are benefited, and the smaller class, the growers, must take care of themselves by growing and finding ways of distribution for better and cheaper fruit in such quantities as to compete successfully with foreign imports, or by devoting their land to a more remunerative industry if it can be found. At any rate, there is no reason why our fruit growers should not adopt means for preserving or canning their surplus fruit in plentiful years, as is now so successfully done in America and France.

In any case "C. W. S." need never fear that many bushels of early Plums will be "allowed to rot," since such varieties as Prince of Wales and Rivers' Early pay well for their culture, notwithstanding the drawbacks which he names. "C. W. S." goes on to say: "Now, if late Plums, to come in after the bulk of the foreign produce is over, were grown there would be a good chance of profit arising from their culture," the fact being that late Plums are now grown far more extensively than the other kind's. Mr. Dancer, of Chiswick, has long known the value of late Plum crops, and his quarters of such sorts as Prince Englebert and Belle de Septembre amongst others are generally well cropped with fine marketable fruit by the ton, while Messrs. Rivers, and the yet more extensive Pershore growers, have long known the value of both early and late fruiting Plums. The inexperienced might be led by "C. W. S.'s" remark to infer that early Plums were a failure generally, and late fruiting kinds not generally grown for market.

Some time ago I made what I thought at the time to be a very moderate, comparative statement, namely, that "in order to fatten a bullock, we require at least the produce of 2 acres of good land for three years, after which, the animal is worth from £20 to £30, while on the same ground we could have grown at least £100 worth of vegetables and fruit." To this "C. W. S." takes exception, since he says "it fails to fairly represent the case." I venture to suggest, however, that he may have failed to read my statement exactly aright, for, had he done so, I feel sure he would have agreed with me, that any cultivator of average merit could certainly obtain more than £100 worth of vegetables and fruit off "2 acres of good land" in three years. How does this statement fail to represent the case? At any rate I am firmly convinced that the result I mentioned can be readily realised, since £17 or even £20 is not uncommon as an annual return for an acre of good land under a vegetable and fruit crop. Potatoes, Onions, and Strawberries would yield such a return under anything like good management. For so short a tenure as three years, to think of planting fruit trees is, of course, quite out of the question, nor are stock-feeding farmers advised by me to attempt fruit culture unless, indeed, they possess the special technical knowledge, which is as essential as capital towards success in this as in other branches of trade. The assumption made by "C. W. S." that the bullock would be fed on "Grass land" is more than I anticipated, since, when I used the comparison, I did not forget that the cheapest and altogether best way of feeding the animal would be to house it and use pulped root crops and cut fodder from arable land, augmented by Linseed or Cotton cake, as is now the practice of the most experienced of large meat-producing farmers.

As to the extension of fruit culture, to which your correspondent alludes, I have only to say that if increased fruit culture in England, together with increased imports from abroad, have failed to lower prices (as is admitted by "C. W. S.") then it is sure evidence that the general demand is ahead of the general supply, and with our present increasing rate of demand, owing to increase in population, neither ten nor fifty large fruit and vegetable growers would influence the markets, if they would only give us fruit and vegetables as cheap and as good or better than those imported from abroad. Our own home growers must balance the imports, or we, as consumers rather than as producers, must be prepared to pay for foreign fruit and vegetables even more liberally than we have hitherto done; and I see that we paid upwards of £10,000,000 last year for imported fruit and vegetables alone. F. W. BURBIDGE.

Pot Vines.—The past winter has proved a rough time for pot Vines that have been, for want of house room, out-of-doors with a mat or two thrown over the pots. Perhaps it may be said that well ripened and established pot Vines could scarcely suffer injury when so exposed; but all depends upon the way in which they have been grown. In any case, harm may be done by exposure, and none are so safe as those which have the shelter of houses, even though in these they may be partly frozen. Forced pot Vines produce large pithy canes that look well, and perhaps tempt the buyer more easily than Vines grown on a more natural system. Such Vines also produce soft fleshy roots that form a mass round the sides of the pots, and when turned out-of-doors in the summer to ripen, rot or decay

in some way, either from cold, exposure, or excess of moisture. Such forced Vines should never be exposed to the open air, but should be placed in cool houses in the autumn to complete their maturity. In some nurseries Vines in pots are not exposed to the open air at any time; they are not even forced except such as is necessary to start the eyes into growth, and they are finally finished off in low span-roofed houses, in which a gentle heat can be used if needed. Such Vines are remarkably short jointed, the wood hard and wiry, and the pots are full of hard, fibrous roots. These are Vines that any one may plant or fruit with the greatest certainty that they will do well.—A. D.

THE FLOWER GARDEN.

FLOWER-BED ARRANGEMENT.

THE first thing which "Azucena" (p. 211) should do is to improve the soil in the bed, and if, as he says, it is wet and cold, some drainage should be put in the bottom. This will be safest done by throwing the best soil from the top on one side; then take the bad soil from the bottom away altogether, to the depth of 3 ft. if possible; 6 in. of stones or any kind of rubble may now be placed in the bottom, on which place a layer of turf with the Grassy side downwards, to keep the drainage clear. On this make the bed, and have the soil made as good as possible by mixing some old manure with it; turfy loam, with some old charcoal, vegetable refuse, or leaf-mould will do. There are many ways of effectively planting such a bed, but round-headed plants, such as Aralias, do not associate well with sedge-like plants, such as the New Zealand Flax, unless they stand well above them, so as to show their outlines clearly and distinctly. If any system of carpeting be adopted, the permanent occupants should be far enough apart to permit of the undergrowth being seen through the foliage of the others. Allow me to offer the following, as suggestions based upon what I have myself tried and seen done elsewhere:

ARRANGEMENT No. 1.—*Dracena indivisa* in the centre, one New Zealand Flax at each end, and four Yuccas on the flanks, i.e., two on each side, with one plant of *Bocconia cordata* between the *Dracena* and Flax at each end. The *Bocconias* will be an immense improvement in summer. Many other hardy plants may be used in a similar manner, notably some of the *Delphiniums* and *Phloxes*. The *Dracenas* and *Flaxes* will need protection during severe winters. Last winter—i.e., the winter of 1877-8—no protection was required. This year they have had their leaves drawn up together and secured in a cone-shaped mass with matting; then they had a single mat wound round them and, thus secured, with some straw placed round the stems and over the earth at the base, large plants of them have kept safely here.

No. 2.—*Chamærops excelsa* in the centre, with half-a-dozen small *Aralias* grouped round it. Two or three *Lilies* might with advantage be introduced, such as *Lilium auratum*, *lanceifolium*, or *candidum*.

No. 3.—Two plants of *Ailanthus glandulosa* 2 ft. on each side of the centre, longitudinally, with six dwarf plants of *Acer Negundo* variegatum planted round. The *Ailanthus* should be trained to a single stem some 4 ft. high, and should be pruned well back every spring, just before the buds push. The largest shoots of the *Acers* will require a little shortening. This will make a handsome bed in summer when the groundwork is filled in with bright colours; but the plants are deciduous, and this, so far as regards winter effect, will be a drawback.

No. 4.—New Zealand Flax in the centre, and half-a-dozen Yuccas round, with about four small plants of *Tamarix* worked in, so as to effectively balance the whole. The *Tamarix* must be pruned close back every spring.

No. 5.—*Acacia inermis* (standard) in the centre, with half-a-dozen *Aralias* round it, and a couple of plants of *Bambusa Metake*, one on each side the central plant.

No. 6.—*Rose Gloire de Dijon* in the centre not too rigidly trained, with a plant of *Clematis Star of India* planted near it, so as to grow up and mingle with the *Rose*, with half-a-dozen plants of New Zealand Flax, or any others of light, elegant habit planted round.

There are numberless arrangements that might be added in a similar way, all of which would look well in suitable situations. For instance, a good-sized Pampas Grass in the centre, and the remainder of the bed planted with dwarf plants to set the Pampas Grass off to the best advantage, would be a simple and effective arrangement. I cannot help thinking that hardy plants that will require no protection in winter would be the most satisfactory. I know of a similar bed, only larger in size, planted with Yuccas, among which are placed thinly *Bocconia cordata*, and the effect is always pleasing. The ground is carpeted with *Cerastium tomentosum*, but there are numberless dwarf hardy plants that would be suitable for forming the groundwork. A good-sized, pyramidal, variegated Holly would form

a good centre for a bed of hardy plants, or a standard *Rhododendron* with four dwarf, standard, grafted plants of *Cotoneaster microphylla* planted one at each end, and one at each flank, with a variegated *Baccharis* between each two *Cotoneasters*. In short, your correspondent is more likely to be embarrassed by the multitude of plants at his disposal than by a scarcity. The first and most important matter is to provide a good bed of soil. E. HORDAY.

THE INDOOR GARDEN.

NATIVE MOSSES AND JUNGERMANNIAS UNDER CULTIVATION.

WHILE the various kinds of *Lycopods* and *Selaginellas* are much run upon for carpeting purposes in stoves and conservatories, the capabilities of our own Mosses and Jungermannias for ornamentation are, I think, unfairly overlooked—a circumstance somewhat strange, as they receive a full measure of admiration in their native woods. Let me describe an arrangement of Mosses and Ferns, which has been in my little stove for the last two years, and which has attracted universal admiration. My gardener brought home one day a quantity of the larger and more beautiful Mosses from a neighbouring glen, and was so struck with their beauty that he determined to try to cultivate them. He arranged them on pieces of old board about 30 in. by 24 in., fastening them down with fine copper wire, which went through rather than over the Moss, and thus was hidden from view. Into this cushion were dibbled bits of small growing Fern, such as *Adiantum glaucophyllum*, *A. Capillus-Veneris*, *Davallia dissecta*, &c. The whole was then placed in an intermediate stove, with one edge dipping into a huge pot which was kept full of water, and which was itself smothered outside with *Adiantums*, having been used as a water pot for many years in a large Orchid house belonging to the late Mr. Bowley, of Blackrock, county Dublin, from whose possession it passed into mine. The Mosses were thus kept constantly moist by capillary attraction, and soon commenced to grow vigorously, as did the Ferns, notwithstanding there was no soil whatever on the board. When all was proceeding favourably the affair was taken down from the water pot and kept frequently syringed, and it has continued ever since to be a mass of exquisite verdure. From time to time various other small plants were inserted, and all have grown with great luxuriance and seem perfectly happy. Amongst the plants on my board may be noted the following, and I am by no means sure that I have exhausted the list:—Of Mosses, the chief is *Hypnum* (*Thamnium*) *alpestrum*, one of the most beautiful, as well as one of the easiest Mosses to cultivate. Mixed with this are *Bryum* (*Mnium*) *undulatum*, *Hookeria lucens*, *Polytrichum commune*, *P. undulatum*, and *Jungermannia aplenoides*. Of Ferns, *Adiantum Capillus-Veneris*, *A. glaucophyllum*, *A. setulosum*, *A. pubescens*, *Davallia novæ-Zelandiæ*, *D. dissecta*, *Gymnogramma ochracea*, *Pteris cretica*, *Oncyrium lucidum*, *Selaginella Martensii*, and *S. M. variegata*. Of miscellaneous plants, there are *Campanula hederacea*, *Pinguicula grandiflora*, *Anagallis tenella*, *Stellaria media*, *Arundinaria falcata* (seedling), *Torenia asiatica* (the only plants which have survived the winter are those in the Moss), and a small *Hypericum*. Recently I have inserted sundry small Orchids, such as *Dendrobium japonicum*, *D. nobile*, *Odontoglossum Alexandræ*, *Acropera Loddigesi*, &c. They look healthy, but have not been there long enough to speak positively about them yet.

While speaking of Mosses I may mention a very pretty *Selaginella* called, I believe, *helvetica*, which grows abundantly on moist banks in the region of the Tête Noire, and doubtless elsewhere in Switzerland and Savoy. Plants brought thence last summer and wintered in a cold frame are now in good

Snowdrops.—*Galanthus Imperatri*, which is just now in full beauty here, having this season come into bloom somewhat later than *G. nivalis*, is undoubtedly the finest Snowdrop at present in cultivation, some of its blooms measuring more than 1 in. in length. *Galanthus Elwesi*, a rare and beautiful species from Asia Minor, is also now in bloom; it is totally distinct in appearance from all other Snowdrops, and can be at once distinguished by its dwarf habit of growth and by the green blotch at the base of each of the minor petals, which, when the flowers are fully expanded, is very conspicuous. Both the single and double varieties of the common Snowdrop (*G. nivalis*) are unusually fine this year, and although they have been in bloom for nearly five weeks past, the flowers are still in good condition. *G. plicatus* is only now showing its broad leaves above the surface of the ground, and will continue the succession of Snowdrops into April.—HUGO HARPUR CREWE, Calke Abbey, Derby.

Yuccas in the Isle of Wight.—I planted the *Yucca* of which the annexed is a representation about twelve or thirteen years ago, and it has taken well to this place. The climate of the Isle of Wight is evidently very favourable to this tribe of plants, which all flourish here amazingly. The flower-spikes come all from a single stem, and they last in blossom deep into the autumn—sometimes nearly to Christmas. The *Yucca* in question is 8 ft. 3 in. high at the highest point, and its circumference is 24 ft. 6 in. On a lawn it forms a splendid object, and when two or three of them are planted together the effect is soon very striking. There are some other species grown here besides *Y. gloriosa*, but I think this is the best of them.—MARCUS LOWTHER, CAPTAIN R.N., Thornton, near Ryde.

Yucca gloriosa in the Isle of Wight.

Abnormal May Apples (Podophyllum).—Last August, when rambling through the woods a few miles from this city (Dayton), on a sort of botanical tour, I found a small group of *Podophyllum* in fruit. Upon examination I found several abnormal specimens in twos, threes, and fours, and one fine bunch of seven, which I had photographed. Can any of your readers explain the cause or causes of such irregularities? I may add that the plants themselves were, to all outward appearances, normal, and gave no indications why they should produce such monstrosities.—AN AMERICAN.

Oil heating.—Several of your correspondents having lately expressed their opinion that oil stoves are useless for warming greenhouses, &c., I think it right to relate my experience, which certainly does not coincide with theirs. Just before last Christmas the little boiler which has hitherto supplied the heat to my small house completely broke down, and, finding it impossible to get it promptly repaired, I was obliged, in despair, to look round for some temporary means to keep out the very severe frost that then prevailed. I ultimately purchased, for 35s., a petroleum stove, fitted with two 3-in. burners, supplied from a tank holding about one quart of oil. From that time to this the temperature in my greenhouse has not been below 42°. The lamp burns for twelve hours without attention, and actually gives off no smoke, but I admit that there is a slightly disagreeable smell. My plants, which are of a miscellaneous kind, look healthy, and, as far as I can judge, have not suffered in the least; therefore, I intend that the oil stove has served me well, and I shall not be persuaded hastily to discard it.—W. M.

health. In form it resembles *S. apoda*, but it is trailing in habit, not cushion-like, as in the case of *S. apoda*. I do not see it in either Ware's catalogue or Backhouse's.

GARENWOOD PIM, M.A., F.L.S.

Monkstown, Co. Dublin.

THE CULTURE OF PANSIES IN POTS.

I WISH amateur gardeners—those who have a great love for a few specialities—could be induced to take up the culture of Pansies in pots, and grow and bloom their plants in a cold frame in early spring. In this way the rich colours and markings of the yellow ground, the white ground, and the self Pansies are seen to the best advantage in the cool, bright spring weather. The flowers are large, stout, and of fine shape, the colours rich, and the belting surrounding the ground regular, and of that glossy richness of surface and texture peculiar to the Pansy. Twenty-five years ago I had something to do with growing them in this way, but that was the day of Pansy societies, and when prizes were offered at the London shows for Pansies in pots. It is a fact that the encouragement given to certain plants, by reason of the places assigned them in prize schedules, has much to do in the direction of encouraging their culture; but I would have Pansies grown in pots for the sake of the pleasure they afford, and, when successfully grown, the great reward they bring to the cultivator. It is not too late to set about the culture of Pansies in pots, provided some good young plants, struck from cuttings taken in July or August last, could be had well established in small pots. In the days I have referred to it was customary with the Pansy growers to pot up a good portion of their plants in small pots, and winter them in cold frames, and good plants could be had all through the winter. It would not be difficult to obtain such plants now, especially from the Scotch florists, but they are not so common in the south of England as they used to be. Pansies for cultivation in pots should be grown from cuttings and not from divided parts of the plants. Healthy, well-rooted cuttings make vigorous, stocky plants. It is best to begin in October or by the beginning of November potting the plants into 5-in. pots, as this gives them a good start and enables them to get well established. The plants can be safely wintered in a cold frame having a dry bottom, as damp is the greatest enemy to the plants during the dead season of the year. All the water necessary during winter is just sufficient to keep the plants alive, and air should be given on all favourable occasions. If sharp frost sets in some covering ought to be placed over the frame while it lasts.

The next stage is that of shifting into the blooming pots; this should be done about the end of February or early in March, selecting the size of the pots to suit the character of the plants; the largest can go into 8-in. pots, the smallest into 6-in. or 7-in. pots. This done, the plants should be encouraged in every way to make a free, stocky growth, taking care not to keep them too close and so imparting to them a drawn appearance. A cold frame, with the plants resting on a well-drained bed, is the best convenience for the plants; the spot should be cool and somewhat moist, and it shaded by trees during the middle portion of the day so much the better. Under such circumstances, and with due attention, the Pansies can hardly fail to do well. Years ago growers in pots for show purposes used to stimulate their plants freely by giving them strong doses of liquid manure. Modern growers have modified this course of treatment, finding they lost plants through overfeeding. Just as the flowers are expanding some weak manure water can be given once in the morning, but having the plants raised on inverted flower pots, so that a quick drainage can be secured. A good compost for Pansies is made up of one-half good fibry loam, one-third old rotted cow manure and horse droppings that crumble almost to powder, and the remainder well-sweetened and thoroughly-decomposed leaf-mould. Liquid manure has been referred to, and to have this handy for use, two tanks, or a tank in two divisions is required. In one division should be put some fresh sheep and cow manure, and a little pigeon's manure if it can be got, and on this water should be poured, and the whole well stirred up together; then it should be allowed to subside until the surface-water is clear, and the clear liquid drawn off

into the other division and used, diluting it as may be thought best. Liquid manure should not be used very strong for Pansies in pots.

Those who make a point of growing flowers in pots, are always careful to keep up a supply of good plants from cuttings. The first batch of cuttings are taken in June, and when the plants from which the cuttings have been taken have done flowering, they are cut down to the ground, leaving any young growths that may be coming up from the roots. They are then top-dressed, and set out-of-doors in a shady place, and finally turned out into the open ground in August, and planted into a prepared bed under a north wall or hedge. The soil for such a bed can be got from the siftings of the refuse soil from the potting-bench, and the plants mulched with a little spent manure from a mushroom bed, to keep the surface cool and moist.

It is scarcely necessary to give a list of varieties. Any florist would be able to recommend and supply a suitable selection; only let the cultivator take care, as far as he can, that they are strong, healthy, and well-wooded plants, and, as such, worthy of his care and attention. D.

OSMUNDA PALUSTRIS.

LIKE the Brake, the Fern-Royal has a very wide range of distribution, and consequently presents a great variety of forms, some of which climate and other conditions have so much differentiated that, taken by themselves, they would be regarded as distinct species. The Fern Royal is distributed all over Europe and Asia, (excepting the Arctic regions), Tropical and South Africa, and the Mascarene Islands, and in America from Canada to Uruguay. *O. regalis* var. *palustris* is an American variety occurring in Central America and Brazil, and one of the prettiest of the genus. The accompanying engraving gives a good idea of the beauty of this Fern, reduced to about one-sixth of its natural size. It has alternately been regarded by different writers as a species and variety, and, like too many other Ferns, has received a number of different names. Milde enumerates the following in his elaborate monograph of the genus: *O. palustris*, Schroeder; *O. spectabilis* var. *brasilensis*, Greville and Hooker; *O. spectabilis*, Martins and Galeotti; *O. mexicana*, Fée; *O. spectabilis* var. *palustris*, Presl; and *O. pulcherrima*, Pohl. The pinnales are finely and elegantly toothed, a character which could not be shown in this very much reduced representation of the plant. I know nothing of the history of its introduction, but it comes nearest to the *O. gracilis*, figured in Lowe's "Ferns, British and Exotic," viii., t. 4. It is well grown in Mr. Williams' nursery at Holloway, whence our illustration was obtained. W. B. HEMSLEY.

CROTONS FOR TABLE DECORATION.

AMONG ornamental foliaged plants suitable for decorative purposes none are more beautiful or useful than Crotons, some of the newer varieties of which have not only magnificently coloured leaves, but are also very remarkable as regards shape. One of the most peculiar in this respect is *C. interruptum*, with which Nature has played some strange freaks by forming gaps in the leaf-blade, and these occur regularly on each side, leaving only the midrib for a distance varying from 1 in. to 2 in., when it again assumes the ordinary character for a short space till there is another break, and so on, which, together with the rich veining, renders the plant very interesting. There is another curious kind named *spirale*, which has leaves about 1 ft. long, with a regular spiral twist from top to bottom, and, as these are narrow and beautifully coloured, it is particularly adapted for use on dinner tables, as are also many of the others. One of my special favourites for this purpose is *C. Wiesmanni*, which has long, narrow foliage of a pleasing green shade, veined regularly throughout with bright golden-yellow, the effect of which, seen under artificial light, is greatly heightened and intensified. A pair of this and a well-coloured *Dracaena Cooperi* for the centre, or *vice versa*, is simply perfection, as, being somewhat of the same type and habit of growth, they associate well together. Another fine variety for a similar purpose is *C. angustifolium*, which has long,

narrow leaves that droop in a very graceful manner, and these, as soon as they attain a little age, become brilliantly tinted, the midrib being of a bright glowing crimson. When required for table decoration, the best way is to start with young plants and grow them on with single stems clothed with foliage right

fibry peat and sand, and grown in the warmest part of the stove, keeping them well up to the glass, in order that they may have the full benefit of the sun, as without that they do not assume the rich leaf markings for which they are so highly prized.

Osmunda palustris.

down to the pots, an easy matter to accomplish, if the points of any strong shoots be taken off and struck, which may be done by inserting them in sharp, sandy soil in single pots, and placing them where they can get a strong, moist heat. As soon as they are struck, they should be shifted on into rough,

Beautiful, however, as are the above-named Crotons, and many others that have been in commerce for a long time, they are likely to be eclipsed by several of more recent introduction, as, on going through one of the London nurseries some time ago, I was much struck with the appearance of one

called Lord Derby, and, although many of the plants were only small ones, they were conspicuous among a whole houseful of others for the striking colour of their foliage, which, in most kinds, does not become at all marked till they attain some considerable size. If this should turn out to be a good grower, as its appearance would lead one to suppose, it will be much sought after for exhibition purposes. Although not at all equal to it in point of colouring, *C. Disraeli* resembles it in form, but those who are so fortunate as to have the first can well dispense with the latter. *C. Mortii* is a very desirable kind to grow in a collection; the ground colour of its leaves is a deep glossy green and the midribs yellow, with the same shade running on into the leaf blades, where it again forms a margin around their edges.

The only drawback to Crotons for general use is that they are very tender, but, for all that, with a little management they may be made available for the embellishment of conservatories during the greater part of the summer. All that is necessary is to place them in the warmest part of the house, where draughts or cold air does not play immediately on them, and, when so situated, if kept tolerably dry at the roots, they will stand until quite late in the autumn without showing the least signs of distress. There is one thing that should be borne in mind, however, and that is, that the transition from the close, confined heat of a stove to that of a cooler house must be gradual if their safety is to be insured, as, with this class of plants, it is sudden changes that work the mischief, by causing them to flag and lose their tender young roots, which get a chill, and, once these are gone, nothing but a brisk temperature will restore them or save the plants from perishing outright.

The habit of most of the large-leaved Crotons is naturally bushy, but in order to make it more dense and compact, the points of all the leading shoots should be nipped out about this time, or the branches should be cut back where the specimens are already large enough, and the pruning to which they are thus subjected will cause them to break again, and to become refurnished with fresh young foliage. When the young growth of such as are pruned back is about half-an-inch long, the plants should be partially shaken out and repotted, but being subjects of a rather moisture-loving nature, it is important that they should have free drainage, for, although in the height of the growing season they cannot well have too much water, their health is injuriously affected unless it can pass freely off. In potting, about equal parts of peat and loam, with a little sand, will be found to answer best, and this soil should be used rather rough and lumpy, but pressed in tolerably firm, and after a day or two watered with tepid water to settle it about the roots. No more should then be given till it gets tolerably dry again, after which, as growth progresses, they will gradually require more. Stiff formal training with Crotons, and indeed with all other plants, should be avoided, as it spoils their beauty; in short, beyond a little adjustment, partaking something of the pyramidal form, the less staking and tying they have the better they look. A few sticks hidden among the foliage may be used to secure the main branches to, so as to bring the frame into shape, after which the regularity of the growth will do the rest.

A good plan to get Crotons well up in colour, is to grow them in houses among other plants that do not require shade, and in order that the tops may be brought up close to the glass, they should be set on inverted pots so as to be above their associates. Thus situated, they get the benefit of a full play of light. To prevent the attacks of red spider and thrips, pests to which they are rather subject, heavy syringings should be given every morning and afternoon during bright days, but should either of these pests effect a footing, hand washing must at once be resorted to, or they soon do irreparable damage. A good soft sponge and soap and water carefully used will soon clean the foliage, and even if there are no insects, the plants quite pay for the labour and time thus bestowed on them by their improved appearance. S. D.

Cœlogyne cristata.—This, in my opinion, is one of the finest of all winter-blooming Orchids, and, what is of equal importance, it is very easily cultivated. We have a small plant of it in a 5-in. pot

bearing at present three spikes of bloom. It has been grown on the back shelf of a Pine stove, where it seems to thrive satisfactorily. On the same shelf a plant of *Lycaste Skinneri* has produced, amongst others, one of the largest blooms I ever saw on any plant of that species. I may just remark, acent growing many plants in the same house, that on the same shelves with the Orchids there are four dozen Black Prince Strawberry plants in 6-in. pots; with from thirty to fifty fruit formed on each plant.—CAMBRIAN.

CULTURE OF *MONSTERA DELICIOSA*.

The structure described by "E. G. L." (p. 193) will suit the *Monstera* very well. The elements of success in the culture of this tropical fruit are heat, light, and moisture, and, provided these necessary conditions be one and all supplied, success will be ensured. Any form of training may be adopted which will bring the plant well up towards the glass. It may be made to cover a portion or the whole of the back wall trellis, or, what is preferable, it may be trained round forked tree stumps, a system which suits it admirably. It may be grown in a tub, but I should prefer planting it out in a good body of fibrous peat and loam in equal proportions, which should rest upon a good drainage of brick rubble. Thus placed, unlimited supplies of water may be given in hot weather, and the fruit will be fine in quality and abundant. One of the best fruited specimens of it which I ever saw was at Cologne; it enjoyed an extensive root-run, and many of the main feeders found their way into a miniature lake; the stems were trained to tree branches, and the fruit was plentiful and good. Although the *Monstera* will thrive in a low temperature, it will not develop its true character as a fruit-bearing plant, unless a brisk growing heat be maintained during the spring and early summer months. If "E. G. L." intends to devote the whole space of his house to the *Monstera*, there will be but little difficulty in growing it to perfection; but if other plants are to be grown along with it, they should not be permitted to crowd it, or in any way obstruct the light from it, and only just enough shade should be given to prevent scorching. J. CORNHILL.

Bylect.

LAPAGERIAS BEST FROM LAYERS.

IN "Gardening for the Week" (p. 163) incidental reference is made to the slow growth of the *Lapageria*, the writer observing that both the red and white *Lapagerias*, when raised from cuttings or layers, are "very slow growers, and must not be over-potted." This is true with regard to cuttings. They take months to strike, and make slow progress afterwards, but not so with layers, which grow fast when well managed. We have a young plant here which originated from a layer put down in November, 1877, and by October following, or eleven months afterwards, it had one strong shoot 8 ft. long, one 5 ft., one 3 ft., and one or two lesser ones. I bought the plant of Messrs. Fisher, Holmes, & Co., of Sheffield, who had at about the same period several hundreds of the same age, with shoots ranging from 3 ft. to 9 ft. in length, and producing abundance of flowers. This was the white variety. These plants had no leading shoots to begin with, but were produced from the leaf-bud, the shoots being layered their whole length with only a portion of each leaf peeping above the soil. The firm in question has been producing stock in this way for years, a house 50 ft. long being set apart for the purpose. The largest plants are at once transferred to 9-in. and 10-in. pots, which were well filled with roots the same season. The success attending the raising of plants in this way has suggested the idea that the best way to grow the *Lapageria* profitably for decorative purposes, would be to raise plants annually like pot Vines. I reckoned that the aggregate length of flowering shoots produced by layers from two or three old plants would be 1500 ft. at least, reckoning the number of plants at 300, their average length at 5 ft., and only allowing one shoot to a plant; but 2000 ft. would be nearer the mark, for many of the plants had from 12 ft. to 18 ft. of wood upon them. During last autumn the whole of one side of the roof of the house was a sheet of white *Lapageria* flowers, from plants under a year old. The multiplication of wood is easily explained. The shoots, when trained on to the roof in the usual way, do not break freely at the buds, but lengthen at their extremities principally, but when they are buried in the soil they produce long shoots from each bud, and also begin to put out suckers at an early stage. Pure peat and sand, plenty of drainage, and plenty of water at the roots, are considered to be the essentials as regards the successful culture of this climbing plant. J. SIMPSON.

Forcing the *Laurustinus*.—Instances may often be found in which the principal merits belonging to plants cultivated in this

country remain undiscovered for years. The Laurustinus has long been employed to ornament our pleasure grounds, but we are only just awakening to the fact that it makes a pretty pot plant, and may be forced into bloom at a very early period of the year. Those who have so treated it this season will have been enabled to fully appreciate its merits. It is useful either as a small compact plant for general decorative purposes, or large specimens may be grown in tubs, to be introduced as required into the stove or forcing house—and they by no means require the lightest and best part of the structure—where they will yield, from Christmas onwards, an abundance of flowers for cutting. Anyone who has a warm house may utilise the Laurustinus to great advantage, as the plants may be placed in a light shed or cold frame, from whence they may be introduced into heat. Where there are corridors and draughty places to decorate, these forced plants will be found as useful as any plant in cultivation, inasmuch as they last so long in flower, and do not show any signs of suffering when exposed to vicissitudes of temperature. It would be well if everyone made a point of keeping a stock of Laurustinus in pots, as, apart from the enjoyment to be derived from them early in the year, they serve to guarantee us against exceptionally severe winters. We from time to time experience a season which cuts off a great portion of the outdoor plants, and our gardens are denuded of this pretty shrub. By propagating every year, there would always be some good-sized specimens available for replacing those destroyed.—BYFLEET.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Treatment of Cyclamens after Flowering.—"Brookhurst" recommends (p. 176) that old Cyclamen bulbs should be placed in the full sun when removed from the conservatory. I have practised this system but I abandoned it, as I found that bulbs thus treated never flowered so well as those which had received protection. It hardly seems fair treatment to expose a plant, which during the spring has received the shelter of a glass roof, and which has probably been even screened from the hot sun, to the vicissitudes of an English summer. Even such hardy shrubs as the Lilac and Deutzia would be much injured, if on removal from the greenhouse they were all at once exposed to the full force of the sun and wind. As an experiment I once placed some Cyclamen bulbs where they did not get any sun the whole summer through, and many of them had nearly 200 blooms on them. I am aware that in its native habitat the Cyclamen grows in the full sun, but the fact of its thriving naturally under sunshine, does not warrant us in subjecting it when in cultivation to great extremes.—J. CORNHILL.

—Having always paid great attention to Cyclamens after they had done blooming, I read with much interest the paragraph which appeared in THE GARDEN (p. 164) on the subject. I am delighted to see prominence given to what is so important to these lovely flowers, viz., the great care necessary during their state of rest, a fact forgotten by almost all amateur Cyclamen growers. There is one question, however, which I should like to ask your correspondent, and that is about the two removals mentioned (p. 164). The Cyclamen is always impatient of removal, but in pot culture one shift is absolutely necessary on account of changing the soil. There are, too, at all times of its growth so many fine, delicate rootlets, which would, under the system of first planting out and then repotting, run a double risk of injury. Would it not be better to move them in July into larger pots and then let them bloom without further check? My plan has always been the same as that which your correspondent recommends up to July, when I take them carefully out of their pots, shake the earth from them, and wash them in tepid water, cutting away any dead roots which I can find. I then pot them and keep them warm for a few days till the roots become established, and then plunge the pots in ashes in a sheltered part of the garden, having them always watered and syringed till the nights become frosty, when they have the protection of a cold frame till they come into bloom. My Cyclamens have been beautiful, some bearing from sixty to seventy blooms, well thrown up above the leaves. I may add that the main thing in the culture of these flowers is, first, to procure and sow the seed in June, when it is fresh from the old plant, to keep the plants well drained and the leaves well syringed, and, last and most important, is the care and culture after flowering.—STAR.

Propagating Bertolonias.—I am well aware that these plants may be increased by means of leaves in the way mentioned by "W." (p. 212), a plan well worth following in the case of those who grow Bertolonias in quantity for sale, but for private places I prefer shoot cuttings, as, with them, one gets a plant up in a condition to show its character in much less time, and taking off the tops helps the plants to break back, and better furnished specimens are the result.—T. BAINES.

ROSES.

CULTURE IN POTS AND IN BORDERS.

CULTURE IN POTS FOR MARKET.—Large quantities of dwarf Roses are grown in pots for the Paris market. These Rose trees come from the district of Le Brie like those which are intended for forcing. They arrive in Paris about the month of November, and are at once laid by the heels in the beds prepared for them. They are potted in the open air during the fine days of autumn, or in winter under a shed. The pots used are 6 in. in diameter, and are filled with a compost consisting of one-third of rotten night soil, one-third of light earth, and one-third of garden soil. The pot, which must be well drained, is filled to a third of its height, and the Rose tree is placed in the middle. The plant is held in the left hand, and the pot is filled up with the right, sprinkling the soil between the roots, and pressing it down from time to time. The Rose tree ought to be so firmly fixed in the pot that it can be lifted up, pot and all, without the latter separating from the ball. The potted Rose trees are then laid in by the heels, the pots being laid upon their sides, and allowed to remain in that position during the winter. In February or March they are planted in borders in four rows, at a distance of 16 in. from each other, in every direction. This method of culture adapts the plants first for the market, and, finally, for being grown in rooms. As there is a large demand for Roses about midsummer, the festival of St. John, and on the occasion of the feast of the Assumption in the middle of August, it is very important that the Rose grower should be well provided with Roses in full flower at these two periods. To effect this it is necessary to reserve several borders specially for plants which must not be pruned, so that the whole of the sap may produce plenty of wood, and a moderate number of flowers at the extremity of the branches. About six weeks before the time when they are required they are pruned, at least two-thirds of the most vigorous branches being cut off, the weakest branches being cut back to the stem. The sap then fills the lowest eyes, which have hitherto remained dormant, causing them to develop themselves fully. The growth of the plants is watched until the new buds begin to form, which generally takes place about the twentieth or twenty-fifth day. Vegetation is then encouraged by copious waterings, giving one watering-potful to every four plants. If the plants are growing too fast they must be checked by giving them a smaller quantity of water, or else by shading them from the light, or, better still, by transferring them to a cold house. By this means the Rose grower can be ready for the market by a particular day, with a well grown stock of plants, which will bring him in from 1s. 3d. to 1s. 8d. each. We have already stated that it is the Rose du Roi and the Aimée Vibert which are best fitted for pot culture. Bengal Roses may also be grown in pots from 5 in. to 6 in. diameter, which are sold from 4d. to 6d. each, while the little Lawrence Pompons may be grown in pots of from 2½ in. to 3½ in. diameter. These beautiful little plants are specially fitted for stands and *jardinières* in small rooms.

BURGUNDY ROSE POMPONS.—The Burgundy Rose Pompons, which belong to the Cabbage Rose class, have produced a dozen varieties, those most usually cultivated being the Rose de Mai and Pompon du Roi, with purple flowers, the latter being the most dwarf of all. The Burgundy Pompon, which is a true miniature edition of the Cabbage Rose, was found in 1735 on a hill in the neighbourhood of Dijon, where it was growing spontaneously; hence its name. In some localities it is called the Pompon de Mai, on account of its coming into its fullest perfection in that month. The buds of this beautiful variety are specially fitted for head-dresses and bouquets for balls. They take the place of winter flowers when they begin to become scarce, and when made into beautiful bouquets with Violets, form fresh, bright, and elegant head-dresses. The Pompon Rose is grown in borders, beds, and clumps. It is very easily cultivated, as every soil seems to suit it; it is, however, best adapted to light soils, in which it blooms much earlier and more abundantly. These two varieties of Roses are propagated by the suckers which they throw up. Every year the roots are earthed up, so as to cause the new shoots to throw out roots, which are separated in the autumn. The

Pompon Rose, when grafted on the Brier, does not seem to thrive, but when cleft-grafted or budded on the Cabbage Rose it seems to prosper. It forms a Rose tree with a full head, and lives a long time without being injured by the frost. In this form it ought to be trimmed down to about $6\frac{1}{2}$ in., a single branch of last year's pruning being preserved. We must also be careful to cut away all the weak shoots which interfere with the form of the head.

DWARF ROSES FOR GROWING IN BORDERS.—Dwarf Roses may be conveniently used in the formation of borders, as well as in beds and round baskets, or on the edges of clumps. Such borders are remarkable, not only for the abundance of flowers with which they are covered during the whole season, but also for the variety of colours which may be obtained by grouping different kinds together, as well as for the ease with which this sort of Rose is cultivated. All that is necessary is to prune the trees so as to induce them if possible to throw out new shoots from their base which will cover the whole of the soil beneath them. To make a Rose border, several parallel or concentric lines are planted, according to the shape of the bed. The Roses are about 4 in. from each other on each row, the rows being 8 in. apart. Less than three lines should not be planted if we wish to obtain a happy effect; we can, however, increase that number, according to the result we desire to obtain. By graduating the height of the plants from the first row to the last, so that they gradually increase in size, or else so that they increase as far as the middle of the bed, and then decrease to the other side, we obtain a bed of single or double slope as we please. The first form is most suitable for the borders of shrubberies, the second for open beds or baskets. We give below the names of those varieties which are most suitable for growing in borders. They must be planted according to their height, the smallest in front: 1. Laurence's Glory, very small flower, crimson-purple; 2. White Pompon; 3. Pompon bijou, light pink; 4. Pumila, a variety of the Noisette, white; 5. Double multiflora, globular flowers, pink; 6. La Désirée, bright pink; 7. De Chartres, half double, delicate pink. J. LACHAUME.

Rose Niphotos.—Canon Hole condemns this Rose, but he qualifies his condemnation by frankly owning that its buds are grown by thousands for the London market to be made up as button-holes, or inserted in the best bouquets. Nor can we honor it more than by using it for the latter purpose. Catherine Mermet, a large, fleshy Rose, I cannot think superb; it lacks the modesty of Niphotos, and Marie Bauman is quite out of the competition, owing to its brilliancy of colour and robustness of habit. As to making Niphotos in paper, the flowers are not to blame; moreover, it is only the most beautiful that are chosen for imitation. Niphotos has but one fault, at least, to my prejudiced eyes, viz., its fragile wood often rendering the blooms invisible without raising them. This renders the plant more suitable for a cool greenhouse than for outdoor growth.—EUGENE E. P. LEGGE, *Litton Cheney, Dorset.*
